Address.

ANCIENT AND MODERN CONCEPTION OF SYPHILIS.

HAIRMAN'S ADDRESS, DELIVERED BEFORE THE SECTION ON CUTANEOUS MEDICINE AND SURGERY, AT THE FIFTY-SECOND ANNUAL MEETING OF THE AMERICAN MEDICAL ASSOCIATION.

WILLIAM L. BAUM, M.D.
CHICAGO.

During the centuries that have elapsed since syphilis ras demarcated as a definite disorder nosologically, iews have appeared, disappeared, and reappeared as o its origin and relation to other disorders. Dominance f judicial astrology, at the time of the Naples epi-lemic, led Steber, of Vienna, in 1494, to claim syphilis s a new disease, due to the conjunction of planets. rünbeck, of Burkhausen, in 1496, charged the disease o the work of Saturn and Mars causing corruption of he blood and bile. Leoniceno, of Lombardy, about he same period, was skeptical as to the occult factors f the origin of the disease. He disbelieved in the origin n divine wrath against blasphemy, which led the em-eror Maximilian to issue an edict. He also disbelieved n judicial astrology, and charged the epidemic to a ertain unseasonableness of the air. He pointed out hat in 1494 inundations occurred all over Europe, and hat it was not surprising that in the wake of such henomena the summer atmosphere acquired those hot nd moist qualities which physicians and philosophers egard as the generating cause of all putrid germs. nundations rapidly develop a general putrefaction of he air and soil. They may not only determine pesti-ential affections —*pestilentia*—like those in the 15th entury, but also prepare for other diseases in the uture.

Here, Leoniceno forms a conception of the relations f syphilis to general nosology, which has since main-ained its own. While syphilis has since been endemic, t rarely assumes a type which could be denominated pidemic. About the time of Leoniceno, the view was ntertained that syphilis was *leprosy modified* by coin-ident nosologic factors. Many 15th and 16th century hysicians believed that syphilis arose from the stings f venomous insects. Indeed, Americus Vespucci laimed that the Indian women used venomous insects o stimulate the genitals of their lovers. In all proba-ility, the peculiarly marked adenopathic character of he epidemic of the 15th century played a large part n lending credence to this venomous insect hypothesis. he adenopathic character of syphilis sometimes ap-ears to-day to an extent that at once puzzles and inter-sts the syphilographer.

No great epidemic has appeared since that of the 5th and 16th centuries. Epidemics of every disease, in the 15th, 16th and 17th centuries, exhibited a decided adenopathic tendency. Constitutional peculiarities at that time doubtless played a large part as predisposing causes, just as the neuropathic tendency of the present day plays a large part in the production of the luetic neuroses.

About 1540, the furibund character of syphilis began to disappear. Probably inherited immunity played a part in this, as well as the fact that the Galenic physicians, stirred by the assaults of Paracelsus, took a more active part in treatment. Antoine Lecocq, in 1540, noticed that syphilis begun to lose its furibund, galloping character. Fracastor, at the same time, remarked that the disease had been markedly modified. Patients had but few pustules and slight shin pains; but more gummata were observed. The hair exhibited a greater tendency to fall out; sometimes the teeth became loose and fell out. The attention of Rabelais was early attracted to syphilis, because his generous disposition drew him toward this neglected class of patients. In 1538 he made great efforts to reform the treatment of these patients at Paris. Rabelais had "often seen syphilitics when greased with mercurial ointment; their faces on edge like a knife and their teeth clacking like the keyboard of a broken-down organ."

ETIOLOGY.

The germ, or animalcular theory of disease, began to assume prominence early in the 17th century. Blankard, a Hollander, had stated: "In the seed of men, and in that moist matter which women carry in their wombs and in their sheaths, are found small animals, which, being venomous, corrupt not only the genital parts, but even, growing in time to large quantities, thrust themselves everywhere in the blood." By the middle of the century even the clergymen were acquainted with this theory. Thus, commingled with the fetichism of Cotton Mather, is found a chapter on the animalcular origin of disease, at the end of which, in describing remedies for this supposed source of distempers, he remarks: "Mercury, we know thee! But we are afraid that thou, too, will kill us if we employ thee to kill them that kill us! And yet, for the cleansing of small blood vessels and making way for the free circulation of the blood and lymph there is nothing like mercurial deobstruents."

Ballay, in the 18th century, claimed that the iguana to which Mark Lister charged syphilis, contained a "small species of animal" which he called venereal virus. He states, much less logically than Mather but in accordance with a view now strongly dominant, that mercury would not have the virtue of curing lues, were it not kept up by small insects, visible only under the microscope. Thirty years before, Ballay, Diedier and Desault had claimed that the venereal leven consisted of "imperceptible worms." Boerhaave strongly opposed.

and, in the opinion of his admirers, completely battered down the hypothesis of the imperceptible worm or animalcula.

The doctrine of disguised venereal diseases flourished. All unusual morbidities which could not be explained were attributed to concealed venereal disease without distinct symptoms. Furstenau charged hysterical phenomena to the driving in of a venereal virus by badly-directed treatment. Rosen, in 1764, made himself the apostle of this doctrine and accepted as hereditary some symptoms of recent syphilis in two 30-year-old patients. Van Swieten, in refusing to admit the heredity of syphilis, momentarily checked this theory. Stoll restored it to its dominance and Fabre was one of its warmest partisans. To a certain extent, this belief was an outgrowth of the tendency to demarcate diathesis which marked the time. Hahnemann, under the influence of this tendency, with that curious distortion of logic which so often suggests in him, paranoiac twist, ignoring the demonstration of the parasitic origin of the itch, charged psora or scabies with being a diathetic state having much more dangerous consequences than syphilis. "This thousand-headed monster of disease does," he remarks,[1] "cause internal affections (after eruptions sometimes containing only a few vesicles), accompanied by intolerable, voluptuous itching, and a peculiar odor. The psora—itch—is the only real, fundamental cause and producer of all the other numerous, I might say innumerable causes of disease—hysteria, mania, epilepsy, convulsions of all sorts, softening of the bones, cancer, gout, jaundice, cyanosis, dropsy, amenorrhea, hemorrhage from the stomach, lungs, nose, bladder and womb, paralysis, and pains of a thousand kinds, etc.—that figure in systematic works on pathology, as peculiar and independent diseases." Despite the demonstration in his time of the itch insect, Hahnemann permanently stamped this etiologic theory into modern homeopathic nosology and therapeusis.

To a certain extent, as to-day, teleologic notions anent the duty of the physician to preach sermons on debauchery in lieu of studying disease, increased this belief in disguised syphilis. Clinical recognition of the anomalies of syphilis, moreover, leads to a bias in favor of syphilitic etiology. Ricord, Dr. Oliver Wendell Holmes remarks, was the "Voltaire of pelvic literature, a skeptic as to the morality of the race in general, who would have submitted Diana to treatment with his specifics and ordered a dose of blue pill for the vestal virgins." While Buret and others have taken up the cudgels strongly for the purely specific nature of syphilis, still the modern trend of opinion strongly favors this 18th century notion, cleared of obscurity by 19th century biochemistry. The toxin of syphilis is now recognized as producing effects non-specific in character and resistant to antiluetic treatment. Lues, like all the great contagions, is now known to produce arrests of development resultant in defective constitutions.

During the 19th century a singular swerving occurred in views held as to lues. While, at the outset of the century, lues was considered as a disease modified by the constitution which it attacked, and the condition of that constitution at the time at which it occurred, by the middle of the century it was looked upon as a disease *per se*, which had little or no relation to constitution or to the patient's condition when attacked. In this particular, opinion concerning it followed the same evolution as views of other contagious diseases. The doctrine of specifics in therapy played no small part in determining this. Lues was likewise separated by nosologists from other diseases, on the teleologic ground that, not occurring in the lower animals, it was a product merely of human debauchery. This view of the disease appeared soon after the great epidemic of the 15th century. Many Galenic physicians, like too many English medical men of to-day, regarded it beneath their dignity to treat a disease of this kind. In England, despite the example of the great biologist, John Hunter, medical men still use venereal diseases merely as a starting point in practice. At the middle of the 18th century it was a common thing for beginners to establish dispensaries for this purpose. Smollett remarks, anent Fathom's attempt to secure practice: "The other means used to force trade, such as ordering himself to be called from church, alarming the neighborhood with knocking at his door at night, receiving sudden messages in places of resort and inserting his cures by way of news in daily papers had been so injudiciously hackneyed by every desperate sculler in physic, that they had lost their effect upon the public and therefore were excluded from the plan of our adventurer, whose scheme for the present was to exert himself in winning the favor of those sage sibyls who keep, as it were, the temple of medicine and admit the young priest to the service of the altar; but this he considered as a temporary project only, until he should have acquired interest enough to erect a hospital, lock, or infirmary, by the voluntary subscription of his friends—a scheme which had succeeded to a miracle with many of the profession who had raised themselves into notice upon the carcasses of the poor.

"Yet even this branch was already overstocked, insomuch that almost every street was furnished with one of these charitable receptacles, which, instead of diminishing the taxes for the maintenance of the poor, encouraged the vulgar to be idle and dissolute by opening an asylum to them and their families from the diseases of poverty and intemperance; for it remains to be proved that the parish rates are decreased, the bills of mortality lessened, the people more numerous, or the streets less infested with beggars, notwithstanding the immense sums yearly granted by individuals for the relief of the indigent."

The "lock" was then, as now, in England, the appellation of a hospital for venereal diseases.

Among the factors charged with the creation of the epidemic in Naples, was bestiality. This opinion was based on a theory that morphology of the contagion is affected by a culture medium. This opinion, experiments of Dr. G. F. Lydston have shown, there is reason to believe, since morphology of both the streptococcus and the gonococcus may be affected by the culture medium. The changeable nature of the vaginal secretions and the difference between human and animal vaginal secretions, were believed to have originated by fermentation—the peculiar qualities of the epidemic lues of the 15th century. While it was long thought that venereal diseases were unknown and incommunicable to animals, investigations during the last half of the 19th century demonstrated the existence of an adenopathic epidemic disorder among horses, known as dourine, and also as *maladie du coit*. This disorder, as Dr. R. J. Withers demonstrated a decade ago, before the Chicago Academy of Medicine, is in many particulars akin to furibund, adenopathic syphilis. It seems to bear the same relation to human syphilis that acute tuberculosis of cattle does to human tuberculosis. Some medical reports of the epidemic of the 15th century refer to syphilis among horses and cattle. Probably much of this was dourine, since horses were then brought in great numbers from Arabia and from North Africa, where dourine is comparatively common.

[1] Organon, p. 113.

The 18th century was marked by clinical demarcations of the different diseases charged to venery. In the early part of the century the distinction between gonorrhea and the other diseases had been pointed out, and had even been used by Swift in his "Tale of a Tub"; still, the disorder remained unnamed until the close of the century, when Swediaur revived the term gonorrhea, under which title—as etymology shows—the Greeks had placed indifferently, blenorrhagia, prostatic discharges and spermatorrhea. Two years after Swediaur, however, Hunter attempted to demonstrate that gonorrhea and lues were the same disease, and, through an undiagnosed lues in a gonorrheic, seemingly proved it. Tode, just before Hunter, had denied the possibility of luetic infection from gonorrhea. Hunter's experiment demolished the position of Tode and pointed out once more that error always lies in absolute assertions. Bell, in 1793, demonstrated that while gonorrhea and lues occasionally complicated each other, they were distinct disorders. The demarcation between hard and soft chancre was not established until 1852, by Bassereau, a pupil of Ricod. This distinction, even yet, is not totally accepted in therapeusis.

The problems of syphilography for the 20th century, as outlined by syphilographers in the 19th century and remote past are:

1. The early diagnosis of the disease where primary sore is either not recognized, as in extra, genital syphilis, or where it is abnormal.
2. The determination as to what predisposition produces the serious nervous and other consequences of tertiary lues.

Arising from this problem comes a secondary one: To determine the predispositions leading to the parasyphiloses. The next thing is to determine the influence of other diseases, whether malign or benign, upon syphilis. The bacteriology and bacterio-morphology of lues and other venereal diseases remain to be worked out. Practically, here, in regard to lues, there is not much advance beyond the guesses of the 17th century. In dealing with bacterio-morphology, the culture medium furnished by various lymphatic systems of man and animals needs determination. Since dourine in epidemic type has frequently to be dealt with by state veterinarians, material can be procured which would throw the same light on lues that lung plague in cattle has thrown upon pneumonia, and that cattle tuberculosis has thrown upon phthisis. In therapy, the problem is to avoid excesses of mercurialization and iodization, to treat secondary mixed infections and toxemias, and to treat the general systemic nervous exhaustion as well as the mental state of the luetic patient. Syphilographers practically must recognize that co-existent syphilophobia is almost as much of a physical depressant as syphilis itself.

Culices Make War on Anopheles.—Sir William MacGregor, governor of Lagos, British West Africa, in a paper read at the British Medical Association, stated that he had placed twenty each of the larvæ of the culex and the anopheles together in water. The anopheles were soon destroyed by the culices, showing that the latter might be made use of as an exterminator of the malaria-propagating anopheles.

INTRA-UTERINE AMPUTATIONS.

PROBABLY CAUSED BY FIBRIN ABNORMALLY PRESENT IN THE LIQUOR AMNII.*

J. MAHER, M.D.,
OAKLAND, CAL.

Intra-uterine amputations are of sufficiently frequent occurrence to excite professional curiosity as to the causes which produce them. I wish briefly to call your attention to a case which occurred in my practice, and I do so perhaps more for the purpose of seeking light than of exploiting a theory.

Two and a half years ago, while officiating as obstetrician, I found a baby which had just been born minus some fingers and toes. I did not know of the abnormality until my attention was called to it by the nurse on the occasion of my next visit, some fifteen hours after the birth. I then found constricting bands of what appeared to be dried fibrin encircling several of the fingers and toes, which were evidently doing the amputating.

After the constrictions had been removed some of the members in the course of time fell off, having been strangulated to such an extent that they could not recover. Others remained and still show very distinctly, as you see by the photographs, the marks of the constricting bands. Fingers which had already been amputated were undergoing re-amputation at points nearer their origin. In other cases two members were cut off by one constriction and at the same time united to each other at the point of amputation. This happened to the two fingers involved on the right hand, which were afterwards separated by the knife.

The baby which was the first one was normal in all other respects and is to-day strong and vigorous. The parents are healthy. Family history is good. The second baby, now a month old, was born in normal condition.

It is not my intention to theorize, but I am inclined to the opinion that the trouble in this case arose from the abnormal presence of fibrin in the liquor amnii.

The causes of intra-uterine amputations, as given by the text-books, are: amniotic bands, inflammations, intra-uterine fractures, and constrictions by the cord. It would seem reasonable also that the amniotic bands so called might be due to fibrin deposited upon a part from the liquor amnii in the same way that it is deposited by whipping fresh blood, constricting the part, causing arrest of development beyond the point of constriction, and subsequent amputation.

The liquor amnii during the first half of pregnancy being almost pure blood serum, this phenomenon might be caused in the same manner as thrombus, embolus, or heart-clot. The liquor amnii may be open to unknown sources of contamination or the accidental introduction of the so-called fibrin ferment and the membranes could offer but poor protection to a fluid so easily infected.

The exact origin of the amniotic bands is not stated in the books, but the majority of writers leave us to infer that they are *all* out-growths from the inner surface of the amnion, and here is where I wish to respectfully take issue with them.

---

* Read at the Fifty-second Annual Meeting of the American Medical Association, in the Section on Obstetrics and Diseases of Women, and approved for publication by the Executive Committee of the Section: Drs. A. H. Cordier, W. E. B. Davis and Henry P. Newman.

Lusk says: "An abnormally small quantity of liquor amnii is, however, only of importance in the earlier stages of fetal development. If the amnion be not then separated from the fetus by an adequate amount of fluid, abnormal amniotic foldings and adhesions between the amnion and the surface of the fetus may take place. The so-called feto-amniotic bands thus formed may, by mechanical compression, result in various fetal deformities or in spontaneous intra-uterine amputation."

Muller says: "Adhesion between parts of the fetus and the amnion are favored by a deficiency in the amount of amniotic fluid. If these points of adhesion become firmer or vascular they may persist, and if the process develops at an early term of fetal life, the regular development at that point will be arrested, giving rise to morphological anomalies which consist in the failure of union between two parts, such as hare-lip, exstrophy of the bladder, etc. If these amniotic bands are attached to the edge of fetal cleavage the cavities are particularly likely to remain open, giving rise to ectopia."

Again, I quote from the "American Text-Book of Obstetrics": "Amniotic bands disturb the development of the extremities, chiefly by producing constrictions causing at the peripheral end edema or atrophy. If this strangulation takes place at a very early date of fetal life then the growth of that part will be greatly arrested, so that the peripheral end beyond the constriction is proportionately small; in other cases it produces death of the part and so-called spontaneous amputation." The same authority says: "It is now generally admitted that the existence of amniotic bands is one of the causes for intra-uterine amputation. This amputation usually takes place early in fetal life. Sometimes there are a number of these bands and they persist to the time of birth."

These writers describe exactly what happens. But I wish to suggest that adhesions between the amnion and the fetus are more apt to cause distortions, producing so-called monstrosities, than clean-cut amputations. In the case here presented, we have no good reason for believing that what occurred was the result of contact with the amniotic surface or of a lack of fluid. When we stop to consider the position of the fetus in utero with legs drawn in, and the arms flexed and folded, it appears to me quite improbable that these members ever come in such constant and intimate contact with the amnion as to become adherent, but that, being the parts which are free and in almost continuous motion, they pick up the fibrin from the liquor amnii when it is abnormally present.

The question arises, would such a deposit of fibrin with the consequent constriction and atrophy taken in connection with the movements of a vigorous baby amputate *any* limb? I have seen a case where both arms and both thighs were taken off at or about the junction of the middle and upper thirds. The subject of this mishap was until quite recently a member of the British Parliament.

Trailing Skirts.—Notices are posted in some places in Switzerland informing wearers of trailing skirts that they will be fined. At Ems, Prussia, trailers are not allowed in the public gardens.

ECTOPIC PREGNANCY, WITH REPORT OF A CASE OF OVARIAN PREGNANCY.[*]

WILLIAM H. WATHEN, A.M., M.D., LL.D.
Professor of Abdominal Surgery and Gynecology in the Kentucky School of Medicine; Fellow of the American Gynecological Society; Gynecologist to the Louisville City Hospital and to the Kentucky School of Medicine Hospital, Etc.
LOUISVILLE, KY.

I do not believe that it is possible for an ectopic pregnancy to develop primarily in the peritoneal cavity, for the ovum can not be lodged securely in any one place sufficiently long to form chorionic attachments, and the peritoneal secretion would very soon destroy its vitality; the one or more cases of reported abdominal pregnancy, after removal of the uterus, were primarily tubal or ovarian, these organs not having been removed with the uterus.

Ectopic pregnancy must be primarily tubal, tubo-ovarian, or ovarian, but as it can not develop to term in any of these structures, it ruptures either into the folds of the broad ligament or into the peritoneal cavity; and if the chorionic attachments are not then destroyed, there is no reason why the pregnancy may not continue to term.

I believe that most cases reported as intra-peritoneal pregnancy are extra-peritoneal, having developed in the folds of the broad ligament, or having then separated the peritoneum from its attachment, either extending upward posteriorly, or anteriorly between the peritoneum and the abdominal wall.

A case recently reported, in *American Medicine*, by Drs. Cullen and Goldsborough as probably abdominal pregnancy resulting from rupture of the uterus, is evidently a case of extra-uterine pregnancy, being primarily tubal, which ruptured into the layers of the broad ligament, and then separated the peritoneum from the anterior abdominal wall; and when they entered the cavity containing the fetus and membranes they did not open the peritoneal cavity. I make this positive assertion, because I am sure that if they will carefully examine the uterus of the woman they will find it in a normal condition. I refer to this case because of the prominence of the parties, thereby emphasizing the fact that there is generally an error in the diagnosis of what is styled intra-peritoneal or abdominal pregnancy. While the pregnancy is primarily nearly invariably tubal, or tubo-ovarian, there are two cases recently reported where it is claimed to have been shown to be primarily ovarian; namely, the case of Dr. G. P. Anning and Mr. Harry Littlewood, and the case of Dr. Catherine van Tussenbroek, as will be seen in the following extract,[1] and in a letter from Dr. Bland-Sutton.

DR. G. P. ANNING and MR. HARRY LITTLEWOOD read a paper on a case of primary ovarian pregnancy with rupture fourteen days after last menstruation.

The patient was aged 28 years, married five months, with no previous pregnancy. Menstruation was usually normal. She was operated upon on August 27, 1900, for a ruptured ectopic gestation, about thirty-six hours after the rupture. About two pints of blood and clots were removed, and a small ovum about the size of a Barcelona nut was found. This fitted into a firm envelope composed of laminated clot. There was a rent in the right ovary leading to a cavity, which contained some blood; into this the ovum and its sac exactly fitted, clearly indicating the primary ovarian origin of the pregnancy. The right tube was removed, and showed no evidence of rupture. The left tube was examined and found normal. The cystic portion of the left ovary was removed. The patient made a good recovery. The specimens were shown, with microscopical sections of the ovum, the sac, and a portion of the ovarian wall.

[1] *British Med. Jour.*, Jan. 12, 1901.

MR. BLAND-SUTTON remarked that belief in ovarian pregnancy could be traced back more than two centuries, but a critical examination of recorded cases, showed that in some instances the supposed ovarian fetus was in reality a dermoid, and in others a sequestered fetus (lithopedion) in the broad ligament. In a few instances the account of the dissection was so careful and circumstantial as to leave the impression that the formation of the embryo in the ovary could not be denied. It must also be borne in mind that the modern cases prior to 1899 rested upon no safer evidence than the non-detection of the ovary during an operation or upon the postmortem examination of a person with an advanced extra-uterine gestation. Even so careful and judicious a writer as Dr. Farre did not deny the possibility of a spermatozoon entering an ovarian follicle, but he denied that any case of ovarian gestation had been satisfactorily proved. Mr. Bland-Sutton came to the same conclusion after a study of a much larger number of specimens than were available to Dr. Farre, and with the advantage of modern methods of histological research. His (Bland-Sutton's) investigations had been particularly directed to the very early stages, for he urged as a postulate that, if the ovum was really capable of being fertilized in its follicle, "an early embryo in its membranes contained in a sac in the ovary" should be forthcoming. He was convinced that the specimen now before the Society was an example of early ovarian pregnancy. The only possible objection that could be raised to this view depended on the fact that the authors had not taken any steps to prove that the "mole" had not been ejected through the celomic ostium of the tube (tubal abortion). He would not press this objection because he had sections of a more complete specimen which quite satisfied him that an ovum could be fertilized while in its follicle. Since the last meeting Mr. Bland-Sutton had visited Amsterdam, and through the courtesy of Dr. Catherine van Tussenbroek, had been able to see the early example of ovarian pregnancy described by her, and had brought back sections which would be available for inspection by any Fellow of the Society. The condition of the parts was exactly analogous to that of a tubal mole, so that for convenience of reference it would be spoken of as an "ovarian mole"; the blood corpuscles in the vessels of the villi were nucleated; there was no trace of a decidua in the ovarian follicle, and it was an interesting fact that in the clinical report of the case it was stated that a decidua had formed in the uterus, and a few days after the operation was discharged with the *douleurs d'accouchement*. The "mole," with its chorionic villi which had become the criterion for many cases of early tubal pregnancy, seemed likely, from this specimen, to become the criterion of early ovarian pregnancy also, and a large field of inquiry had thus been opened, for the condition known as blood cysts of the ovary would now require very careful investigation in the new light afforded by this specimen.

"LONDON, May 7, 1901.

"Dear Doctor Wathen:—The sac in the van Tussenbroek specimen contained an embryo. I satisfied myself on this point when examining the sections. That case is complete in every particular. Yours very truly, J. BLAND SUTTON."

"P. S.—No embryo was found in Anning's case. The van Tussenbroeck case was reported in extenso in the *Ann. de Gyn. et de Obstet.*, under the title "Un Cas de Grossesse Ovarienne."

By studying this extract carefully, and Dr. Sutton's letter, it will be clearly seen that in no case has an embryo ever been seen, and the assertion that there has been an embryo rests solely upon macroscopic and microscopic examination of the membranes. I contend that the opportunities for error in such examinations are so abundant that it is doubtful if we are justified in accepting such cases as genuine unless the embryo can be seen, as in the specimen I now exhibit, which must be accepted as positively ovarian, unless we deny that any case can be such with the tube not patulous in its entirety, with no closure of the outer extremity. By examining this specimen, you will see that the tube has not been ruptured in any place, but that the fimbriated extremity has become adherent to the sac cavity, which I claim is the result of an irritation caused at the time of rupture, and hemorrhage.

It is a well-known fact that, in all structures in the peritoneal cavity nature tries to protect the life of the individual by a rapid formation of adhesions to prevent further extension of injury, and why should there be an exception in this case?

As microscopic examinations show that sections taken from all parts of the sac from which the laminated clot containing the embryo was removed are positively ovarian tissue, there can be no doubt as to the impregnation having occurred in the Graafian follicle, and that the ovum never escaped from this cavity. Within the center of the laminated clot, there was an unbroken amnion containing an ounce of liquid, and an embryo of about six weeks' development in a state of perfect preservation, which can be seen by examining the specimen.

If ectopic pregnancy be diagnosticated before rupture, there is no operation in which the peritoneal cavity is opened that is more easily performed, or more successful. This may be accomplished by either the vaginal or the abdominal route. After the rupture has occurred, the selection of the method depends upon the condition existing. If the rupture is in the folds of the broad ligament, with few exceptions the operation can be completed successfully by the vaginal method; and I have within the last five years performed nine-tenths of my operations for ectopic pregnancy by this method, and have had but one death, which was the result of long delay and general sepsis before the operation. So demonstrated facts outweigh theory of those who oppose the vaginal route.

If the rupture is intra-peritoneal, the operation may often be performed by the vaginal method, and if conditions are encountered that can not be overcome, we may speedily open the abdomen and have the advantage of excellent drainage from below; this greatly aids convalescence, where the pelvic and abdominal structures have been extensively soiled with blood, which may have become infected by passage of germs from the bowel.

In cases of great shock, where the patient would probably die if an abdominal section were performed, we may control hemorrhage and establish drainage through an incision into Douglas' pouch, by bringing down the ruptured tube and applying a clamp over the bleeding point; this may be left in position, giving positive assurance that there will be no hemorrhage until the woman can be stimulated and gotten into a condition favorable for an abdominal section; it may be done without the administration of an anesthetic or greatly disturbing the woman. In fact, all operations for extra-uterine pregnancy before the end of the third month, where there is not great shock, may be performed so easily and so successfully that a description of methods is hardly necessary. This, however, is not true in cases that have continued to develop for several months or to term after rupture from the tube. In these cases, we would have no trouble were we able to remove the placenta and control hemorrhage. The dangers of sepsis and secondary hemorrhage are so great if the placenta be left, that we are justified in encountering the dangers of hemorrhage in efforts at its removal. If we attempt to separate the placental attachment without facilities to control the blood-vessels speedily, our patient may die of hemorrhage before we can reach the bleeding points; therefore it is best to have a large assortment of long and varied-shaped forceps, which may be applied at many points before the separation of the placenta is attempted.

If we wait to apply the forceps to all points after the separation the hemorrhage may so obscure the surface that we can not succeed. It is nearly impossible in these cases to use ligatures to an advantage before the placenta is separated, but they may be applied afterward when we have controlled hemorrhage by forceps, just as we do when we control hemorrhage by forceps in the removal of uterine myomata; for the large vessels will then have become greatly contracted. Firm gauze pressure may aid in controlling hemorrhage.

Of course, there can be no well-established technique that will apply to every case, because in one ectopic pregnancy that goes to term we may open directly into the sac cavity and not expose any intra-peritoneal structures; while in another the peritoneal cavity will have been opened and the placenta found attached so widely that it seems nearly impossible to separate it without fatal hemorrhage. Again, the attachment may be such that the placenta and membrane may be separated without causing profuse hemorrhage. If in any case the placenta can not be or is not removed, a large opening should be made into the pouch of Douglas so as to establish free drainage, and if possible the fetal sac should be sutured into the lowest part of the abdominal incision, thereby protecting the peritoneal cavity.

DISCUSSION.

Dr. A. Goldspohn, Chicago—Every case that can be actually counted as a case of ovarian pregnancy is an object of much interest inasmuch as that question does not seem to be definitely decided. We know that Dr. Wathen is one of the advocates of the vaginal route. The difficulty about forceps, which he speaks of, to control hemorrhage and about not being able to ligate the arteries through the vagina is considerable and unnecessary. We know that extrauterine pregnancy is a sterile condition. Drainage and ventral hernia as objections to the ventral incision can be avoided. If the rupture has occurred some time back, so that the source of bleeding has certainly been occluded, that the hemorrhage is not continuing and has not been progressing, we then have an hematocele to deal with. To clean that out, the vagina is a good route, but when we are not certain that hemorrhage has been definitely stopped and that natural hemostasis has occurred, we have to operate, not simply to empty an hematocele, but also to stop hemorrhage. Then the route by abdominal section is to be preferred. Also, because many of these cases have some true gynecologic reconstruction work to be done, it can be done intelligently and to best advantage to the patient by means of an abdominal section.

Dr. Wathen, in reply—Dr. Goldspohn misunderstood me in relation to drainage. When I operate from below in a case of large hematocele, I drain because it is necessary, no matter whether the hemorrhage has stopped or not. We can not always tell that, but we generally can control it from below by opening and taking out the hematocele, bringing down the ruptured tube, and removing it. What I spoke of, in drainage, was that if we succeeded in operating from above and failed to take out the placenta, it would be well to drain. Where there is simply a freshly ruptured ectopic gestation, or no rupture at all, there would be no necessity for drainage unless you soiled the cavity yourself. I do not believe in drainage by the abdominal route. I have not drained for three years. I packed with gauze, but that is simply isolating infected areas. *Per vaginam*, where I remove infected or non-infected material, I always drain, using the drainage tube with gauze, and I get good results. I have not found the case yet of rupture into the broad ligament that I could not control from below. They all recovered, but one. They will always recover if you get them in time. If there is a little hemorrhage, gauze packing will readily control it.

GYNECOLOGY, ITS CONTRIBUTION TO GENERAL SURGERY.*

HENRY O. MARCY, M.D.

BOSTON, MASS.

As we stand upon the threshold of a new century, it is wise that we review the history of the past and garner its lessons for the future.

Until within the latter half of the Nineteenth Century, the practice of medicine had continued in quite the same general way as for the indefinite past. Even surgery, as a specialty, was so exceptional that, after my return from the army service as surgeon, in 1865, my revered master, Dr. Henry I. Bowditch, urged that I abandon my purpose of making surgery my life-work, with the statement that there was but one man in New England who, as a surgeon, obtained more than a competency.

The introduction of ether into general use, followed by the wide experience gained by a large proportion of our younger graduates in the civil war, gave to surgery in America a new impetus, and this, with a very general advance in anatomic, pathologic and clinical knowledge, caused many to fit themselves very carefully, by a long period of study at the various centers of European learning. This enthusiasm has in no way abated, until now, by general consensus of opinion. American surgery is not surpassed, if equaled.

Gynecology is very naturally in origin a subdivision of obstetrics rather than surgery. The older works were usually styled, "Obstetrics and Diseases of Women," oftentimes adding, as did also the professorships, "and Children." This tended to the study of uterine and pelvic pathology rather from the medical than the surgical aspect, and hence arose the very general and now justly criticised methods of intra-uterine and vaginal medication.

The younger members of the profession can never understand the difficulties which hedged about the study of the pelvic pathologic conditions of women at a not very remote date. This was due quite as much to the prudish reserve of the profession as to that of the laity. Dr. Bennett in the preface to the first edition of his work entitled "The Inflammation of the Uterus," published in London, 1845, states, "that in England no examination, even of a married woman, is attempted by the most experienced practitioner unless there be very serious reason for such a step, and very frequently not even then. That this laudable sense of propriety is, however, often carried much too far by the members of the medical profession with us is well known to all who specially study uterine pathology. I might cite numerous illustrations of this fact. One alone will suffice to show how frequently examination is neglected by well-informed practitioners from false delicacy on their part and not that of their patients. A few months ago I was consulted by an unmarried female who had presented for eight years, not a few only, but all the symptoms of uterine polypus. During this period she had been attended for weeks and months at a time by five or six medical gentlemen of undoubted talent and ability, not one of whom ever proposed an examination. They must have suspected the disease. That person has repeatedly told me that she would at any time have submitted to an examination, had she been requested, so great was the intensity of her suffering. Delicacy carried to such an extent becomes absolutely criminal."

---

* Read at the Fifty-second Annual Meeting of the American Medical Association, in the Section on Obstetrics and Diseases of Women, and approved for publication by the Executive Committee of the Section: Drs. A. H. Cordier, W. E. B. Davis and Henry P. Newman.

In my own student days I was carefully instructed to make a small hole in a sheet placed over the patient and through this to examine, and, if thought necessay, to thrust in the long cylindrical speculum, in the almost futile hope of adding to my knowledge. Even as late as 1869 I was obliged to seek in Germany opportunities for physical examination nowhere permitted in America.

Mr. I. Baker Brown was one of the most popular and prosperous of the younger surgeons of London, until after the publication of his very thoughtful and original work entitled, "The Diseases of Women," in 1864. In the surgical reparation of the injuries incident to childbirth he will ever be looked upon as a wise pioneer, but in the attempt to popularize his work he went a step too far for the conservative opinion of the time, and the active opposition of the profession forced him into obscurity and want.

Drs. Burnham and Kimball of Lowell, Mass., were illustrations of professional ostracism by men incapable of judging of their vastly superior merit. To the latter I am indebted for very much of value, and I esteemed his friendship as an especial honor; yet I was advised confidentially by one who was then a leading practitioner in Boston, that if I would succeed in Boston I must ignore him. Yet he performed 225 operations for ovariotomy with 69 per cent. of recoveries. He removed the uterus 12 times with 5 recoveries.

This was in a greater degree true of Dr. Horatio R. Storer of Boston. Educated in a most careful way, four years an inmate of the family of the immortal Simpson, and the editor of his works, he tried in vain to stem the tide of adverse popular medical opinion, and broken in health as a consequence, abandoned his profession. Yet these men made contributions to surgery which have rendered their names immortal. They placed upon a sure foundation the surgical removal of large uterine myomata, and Dr. Storer was the first deliberately to plan and execute the safe surgical cure of umbilical hernia. When this operation, now considered of so little danger, was first made known, the criticism and condemnation here was bitter and almost universal.

The peritoneal cavity and the knee-joint were then thought beyond the deliberate invasion of any surgeon who would maintain the respect and confidence of the medical profession. From a source least expected there arose a new teacher who became famous by dint of industry and a genius rarely surpassed in any field of labor —J. Marion Sims. Unlike McDowell, also from the South, Dr. Sims had had no foreign training. Educated in Charleston, S. C., he practiced in Montgomery, Ala., until on account of illness he removed to New York in 1853. He had worked out with remarkable perseverance, amid discouragements sufficient to have overcome most men, and had established the cure of vesico-vaginal fistula by the use of the silver wire suture, and won thereby a national reputation. Certain instruments were necessary in order to bring the parts within easy manipulation, and I shall never forget his telling me of the happy discovery which almost at once brought into general use the retracting speculum still called by his name. He had noticed that by placing his patient in the semi-prone position and retracting the perineum with his fingers, that the air pressure caused vaginal distention, which he called *ballooning* the vagina. One day, when desiring to examine a multiparous negress in her own cabin, he found himself without instruments. Chancing to see a large iron spoon, he bent back the handle and upon retracting with the spoon-bowl he at once saw the value of such an instrument, placing the entire vaginal vault under easy inspection and control.

When we contrast the difference between the use of the almost universal cylindrical tube, used since the days of the Romans until then, we may well understand the enthusiastic welcome of the new instrument. Dr. Sims is wisely considered the founder of a new department in surgery, since gynecology was almost at once raised from the level of empiricism to the dignity of a science.

The neglected work of Baker Brown was taken up and improved upon. It was not, however, until a number of his enthusiastic female friends organized for the founding of the Woman's Hospital of New York that the work under his hand received medical support. Conservatism hedged him about as with a high wall, while professional jealousy and criticism wellnigh crushed his sensitive spirit.

Ardent in his support of the cause of the rebellion, he would not remain under the flag of the United States, and owing to this he took up his residence in Paris. Here his genius found a new favoring field, and he was received with éclat in all the great centers of Europe. In 1865 he published his remarkable book under the modest title of "Notes on Uterine Surgery."

I first met him in Paris and the charm of his personality is as distinct in memory as yesterday. Upon his return to New York he associated with himself Drs. Emmet and Thomas and for some years it is probable that no one center of clinical teaching did so much to mold medical thought as the modest clinics held at the Woman's Hospital. So popular did his teaching become that the Board of Managers, out of a supposed respect for the modesty of the patients, voted to restrict the number of medical visitors to fifteen. This touched the dignity of Dr. Sims as personally offensive, and he tendered his resignation which in a somewhat similar feeling was accepted. He told me years after that he had always regretted this step as hasty and inconsiderate. The work in the Woman's Hospital continued under the masterful supervision of Drs. Emmet and Thomas, who made many contributions to gynecology of the highest value.

Although to Dr. Bobbs of Indiana is justly given the credit of having successfully performed cholecystotomy, it was undertaken, prompted by a mistaken diagnosis, he believing the enormously distended gall-bladder to be an ovarian cystoma. To Dr. Sims is justly awarded the honor of having, after a careful study of the pathology of biliary calculi, formulated and carried into successful execution the modern surgical intervention for the removal of the gallstones. He is entitled to be called the father of gall-bladder surgery.

In 1847, Prof. Charles D. Meigs, of Philadelphia, published a large volume upon, "Woman, Her Diseases be left, that we are justified in encountering the dangers of hemorrhage in efforts at its removal. If we attempt to separate the placental attachment without facilities to control the blood-vessels speedily, our patient may die of hemorrhage before we can reach the bleeding points; therefore it is best to have a large assortment of long and varied-shaped forceps, which may be applied at many points before the separation of the placenta is attempted.

If we wait to apply the forceps to all points after the separation the hemorrhage may so obscure the surface that we can not succeed. It is nearly impossible in these cases to use ligatures to an advantage before the placenta is separated, but they may be applied afterward when we have controlled hemorrhage by forceps, just as we do when we control hemorrhage by forceps in the removal of uterine myomata; for the large vessels will then have become greatly contracted. Firm gauze pressure may aid in controlling hemorrhage.

Of course, there can be no well-established technique that will apply to every case, because in one ectopic pregnancy that goes to term we may open directly into the sac cavity and not expose any intra-peritoneal structures; while in another the peritoneal cavity will have been opened and the placenta found attached so widely that it seems nearly impossible to separate it without fatal hemorrhage. Again, the attachment may be such that the placenta and membrane may be separated without causing profuse hemorrhage. If in any case the placenta can not be or is not removed, a large opening should be made into the pouch of Douglas so as to establish free drainage, and if possible the fetal sac should be sutured into the lowest part of the abdominal incision, thereby protecting the peritoneal cavity.

DISCUSSION.

Dr. A. Goldspohn, Chicago—Every case that can be actually counted as a case of ovarian pregnancy is an object of much interest inasmuch as that question does not seem to be definitely decided. We know that Dr. Wathen is one of the advocates of the vaginal route. The difficulty about forceps, which he speaks of, to control hemorrhage and about not being able to ligate the arteries through the vagina is considerable and unnecessary. We know that extrauterine pregnancy is a sterile condition. Drainage and ventral hernia as objections to the ventral incision can be avoided. If the rupture has occurred some time back, so that the source of bleeding has certainly been occluded, that the hemorrhage is not continuing and has not been progressing, we then have an hematocele to deal with. To clean that out, the vagina is a good route, but when we are not certain that hemorrhage has been definitely stopped and that natural hemostasis has occurred, we have to operate, not simply to empty an hematocele, but also to stop hemorrhage. Then the route by abdominal section is to be preferred. Also, because many of these cases have some true gynecologic reconstruction work to be done, it can be done intelligently and to best advantage to the patient by means of an abdominal section.

Dr. Wathen, in reply—Dr. Goldspohn misunderstood me in relation to drainage. When I operate from below in a case of large hematocele, I drain because it is necessary, no matter whether the hemorrhage has stopped or not. We can not always tell that, but we generally can control it from below by opening and taking out the hematocele, bringing down the ruptured tube, and removing it. What I spoke of, in drainage, was that if we succeeded in operating from above and failed to take out the placenta, it would be well to drain. Where there is simply a freshly ruptured ectopic gestation, or no rupture at all, there would be no necessity for drainage unless you soiled the cavity yourself. I do not believe in drainage by the abdominal route. I have not drained for three years. I packed with gauze, but that is simply isolating infected areas. Per vaginam, where I remove infected or non-infected material, I always drain, using the drainage tube with gauze, and I get good results. I have not found the case yet of rupture into the broad ligament that I could not control from below. They all recovered, but one. They will always recover if you get them in time. If there is a little hemorrhage, gauze packing will readily control it.

GYNECOLOGY, ITS CONTRIBUTION TO GENERAL SURGERY.*

HENRY O. MARCY, M.D.
BOSTON, MASS.

As we stand upon the threshold of a new century, it is wise that we review the history of the past and garner its lessons for the future.

Until within the latter half of the Nineteenth Century, the practice of medicine had continued in quite the same general way as for the indefinite past. Even surgery, as a specialty, was so exceptional that, after my return from the army service as surgeon, in 1865, my revered master, Dr. Henry I. Bowditch, urged that I abandon my purpose of making surgery my lifework, with the statement that there was but one man in New England who, as a surgeon, obtained more than a competency.

The introduction of ether into general use, followed by the wide experience gained by a large proportion of our younger graduates in the civil war, gave to surgery in America a new impetus, and this, with a very general advance in anatomic, pathologic and clinical knowledge, caused many to fit themselves very carefully, by a long period of study at the various centers of European learning. This enthusiasm has in no way abated, until now, by general consensus of opinion, American surgery is not surpassed, if equaled.

Gynecology is very naturally in origin a subdivision of obstetrics rather than surgery. The older works were usually styled, "*Obstetrics and Diseases of Women*," oftentimes adding, as did also the professorships, "and Children." This tended to the study of uterine and pelvic pathology rather from the medical than the surgical aspect, and hence arose the very general and now justly criticised methods of intra-uterine and vaginal medication.

The younger members of the profession can never understand the difficulties which hedged about the study of the pelvic pathologic conditions of women at a not very remote date. This was due quite as much to the prudish reserve of the profession as to that of the laity. Dr. Bennett in the preface to the first edition of his work entitled "*The Inflammation of the Uterus*," published in London, 1845, states, "that in England no examination, even of a married woman, is attempted by the most experienced practitioner unless there be very serious reason for such a step, and very frequently not even then. That this laudable sense of propriety is, however, often carried much too far by the members of the medical profession with us is well known to all who specially study uterine pathology. Chancing to see a large iron spoon, he bent back the handle and upon retracting with the spoon-bowl he at once saw the value of such an instrument, placing the entire vaginal vault under easy inspection and control.

When we contrast the difference between the use of the almost universal cylindrical tube, used since the days of the Romans until then, we may well understand the enthusiastic welcome of the new instrument. Dr. Sims is wisely considered the founder of a new department in surgery, since gynecology was almost at once raised from the level of empiricism to the dignity of a science.

The neglected work of Baker Brown was taken up and improved upon. It was not, however, until a number of his enthusiastic female friends organized for the founding of the Woman's Hospital of New York that the work under his hand received medical support. Conservatism hedged him about as with a high wall, while professional jealousy and criticism wellnigh crushed his sensitive spirit.

Ardent in his support of the cause of the rebellion, he would not remain under the flag of the United States, and owing to this he took up his residence in Paris. Here his genius found a new favoring field, and he was received with éclat in all the great centers of Europe. In 1865 he published his remarkable book under the modest title of "Notes on Uterine Surgery."

I first met him in Paris and the charm of his personality is as distinct in memory as yesterday. Upon his return to New York he associated with himself Drs. Emmet and Thomas and for some years it is probable that no one center of clinical teaching did so much to mold medical thought as the modest clinics held at the Woman's Hospital. So popular did his teaching become that the Board of Managers, out of a supposed respect for the modesty of the patients, voted to restrict the number of medical visitors to fifteen. This touched the dignity of Dr. Sims as personally offensive, and he tendered his resignation which in a somewhat similar feeling was accepted. He told me years after that he had always regretted this step as hasty and inconsiderate. The work in the Woman's Hospital continued under the masterful supervision of Drs. Emmet and Thomas, who made many contributions to gynecology of the highest value.

Although to Dr. Bobbs of Indiana is justly given the credit of having successfully performed cholecystotomy, it was undertaken, prompted by a mistaken diagnosis, he believing the enormously distended gall-bladder to be an ovarian cystoma. To Dr. Sims is justly awarded the honor of having, after a careful study of the pathology of biliary calculi, formulated and carried into successful execution the modern surgical intervention for the removal of the gallstones. He is entitled to be called the father of gall-bladder surgery.

In 1847, Prof. Charles D. Meigs, of Philadelphia, published a large volume upon, "Woman, Her Diseases and Remedies." This continued a text-book of recognized reference until after my graduation. His teaching is given (in the form of letters) to his class, and he discusses colloquially with his genial "Helen," in a very free way, of her supposed diseases and manifold sufferings. Very little of profit came to the student from its study, and it is now chiefly valuable as a standard by which to gauge the ignorance rather than the knowledge of woman's diseases half a century ago. It is said the good Doctor made simplicity of living a virtue and showed its benefit in a well-preserved physique. He commended walking as the exercise for all, even of the profession. One of his famous sayings reported is the following: "The doctor who drives one horse has weak legs, he who drives two has a weak head."

Surgery can never repay the indebtedness which it owes to Drs. John L. and Washington L. Atlee of Pennsylvania. They revived the operation for ovariotomy in 1843 and were the first in the history of medicine to remove successfully both ovaries at one operation. The first successful ovariotomy ever performed, as is well known, was by Dr. McDowell in 1809. Dr. McDowell operated thirteen times with eight recoveries. The next ovariotomist in America was Dr. Nathan Smith, then professor of surgery at Yale College. His operation was performed July 5, 1821. The third was Dr. A. G. Smith of Danville, Ky., who assisted Dr. McDowell in some of his operations. This was performed in May, 1823. The fourth was Dr. D. L. Rogers of New York, who operated in 1829.

In 1830, Dr. J. C. Warren of Boston reported the thirty-third case on record. He first tapped and two weeks after removed the ovarian tumor. The ligature slipped. "Owing to the shortness of the pedicle, the ligature partially slipped off as soon as the scirrhus was taken away, and though the vessels were secured as fast as possible, they were so numerous and large that the patient in a short time sank from loss of blood." Dr. Warren concludes his remarks on the case and the result of the operation in these words: "The event of this case has led me to decline repeating the operation, and I should advise others to decline it unless there was some peculiar insulation of the tumor, as when it forms a hernia. or when it has a very long and narrow pedicle."

Dr. J. Bellinger of Charleston, S. C., who attempted an ovariotomy in 1828, operated successfully in 1835. No other successful ovariotomy was performed until that of the Atlees above referred to. Dr. Bellinger reports his operation as follows: "Incision extended to the ensiform cartilage; the tumor was removed by cutting the round and broad ligaments. Two arteries of considerable size were tied with animal ligatures, both ends of which were cut off close to the knot; a tumor in the pelvis was formed by the uterus distended with a large quantity of dark watery fluid which escaped by a rent made by the finger through the posterior wall. The patient was still living and in good health, May, 1847; menstruation never returned."

Dr. Vangirard reported in 1847 a case which had been tapped fifty times in three and one-half years. *Ether inhaled;* recovery. Dr. Atlee in 1849, reported two cases; chloroform mixture given. In 1850 he reported a case very troublesome because of a forcing out of the intestines, owing to a state of catalepsy produced by the chloroform mixture. Dr. J. H. Bigelow in 1849 removed a cyst weighing eight pounds; recovery—the first case which I find of recovery in Boston.

Dr. Bellinger's case is especially worthy of note, because of the use of the animal ligature, cut short, and the pedicle dropped back into the abdomen. Others had used animal ligatures prior to this date, but the ligatures were usually left long and brought out through the abdominal wound, that they might be removed later.

It was thought at this time by the profession in general that the previous surgical experience did not warrant surgical intervention. On this account, it made it even more difficult to stem adverse criticism than that which befell Dr. McDowell. In the publication of his experience[1] Dr. Atlee wrote: "I pledge myself to the profession to treat this subject in all truth and candor; to falsify, omit, or withhold nothing; to write down errors, if such there be, in honesty and without fear, taking censure when deserved. In the decision of a matter of such weight to humanity, personal sacrifices ought to be utterly disregarded. If this operation is to be established, it must be on correct statements; if it fails on such testimony, it fails justly and forever. . . . Let the question therefore be met as it should be and its history be a record of truth." Dr. Atlee moved to Philadelphia, where he soon after performed his third operation, the first in the city, in March, 1849. The operation was denounced by the general profession, in the medical societies, and in the medical colleges. He was pointed out as a dangerous man. A celebrated professor, even in a published lecture, invoked the law to arrest him in the performance of the operation.

"The day before I operated upon my patient in Philadelphia, an eminent surgeon called upon her to assure her that she would certainly be dead in twenty-four hours after the operation. Twenty-four hours after the operation I requested him to visit her, and her condition was such that he could not believe she had been meddled with until I exposed the wound."

In 1852, the Northern Medical Association passed the following resolution: "That this Association, viewing the numerous fatal results ensuing upon ovariotomy and the many disasters arising from errors in diagnosis, unreservedly deprecates the frequent performance of this operation as detrimental to the best interests of science. and fraught with the most imminent hazard to life."

The following autumn, the same society reviewed the subject carefully and passed a resolution no less condemnatory.

Dr. Atlee was indefatigable in his researches upon the history of ovariotomy in every country and gathered a statistical table of 101 operations, which he published in April, 1845. In 1851, he published a new edition of his table, then containing 222 cases.[2]

There were in America 27 cases only. So slowly did ovariotomy find favor with the profession, because of the excessive mortality, that the total number of reported cases in the United States up to 1864 was only 117, of which nearly 60 per cent. recovered. Even as late as 1863, there are only three cases reported in that year, with two recoveries. From January, 1864, to October 10, 1871, the number rapidly increased to 622. Of this number, 246 cases, with 70 per cent. of recoveries. were operated upon by Dr. Atlee alone; 121 by Dr. Gilman Kimball, of Lowell, with 70+ per cent. of recoveries; 60 by Dr. A. Dunlap, of Ohio, with 80 per cent. recoveries; 28 by Dr. E. R. Peaslee, with 67+ per cent. of recoveries. Dunlap's cases show the highest percentage of recoveries. The total of the four operators give 455 cases, with an average of about 70 per cent. of recoveries. Total number of cases in the United States, 739.

---

[1] American Journal of Science, April, 1845.

[2] Transactions of American Med. Assn., 1851.

The total number in Great Britain at the same date was 1006, the list being headed by Sir Spencer Wells with 440 cases, recoveries 74.54 per cent.; Charles Clay with 250 cases, recoveries 72+ per cent.; Thomas Keith 136 cases, recoveries 81+ per cent.; T. Baker Brown 120 cases, recoveries 70+ per cent.

In France up to 1867, there had been only 116 cases reported, with only 40.51 per cent. of recoveries. In Germany up to 1870, there were 180 cases, with 41.66 per cent. of recoveries.

The gravity of all these cases was greatly increased owing to the pathologic changes incurred by delay, as the rule then was not to attempt operation, because of the great fatality resulting from peritoneal injuries, until after twice tapping. Thus, extensive adhesions, reduction of vitality, etc., were the rule rather than the exception.

It is not my present purpose to follow the history of abdominal surgery beyond the advent of antiseptic teaching and practice. Owing to the indomitable heroism of the few already referred to, whose memory will be cherished, the battle over ovariotomy had been fought and won before our knowledge of wound infection had been placed upon a scientific basis. To a considerable degree this was also true, in favorable cases, of uterine tumors.

To Drs. Burnham and Kimball, of Lowell, belongs the undisputed honor of being the first deliberately to plan and successfully carry into execution that which is now justly considered one of the greatest triumphs of modern surgery—the comparatively safe removal of uterine myoma.

All along the lines, however, the details of operative measures were actively contested; the treatment of the pedicle, the closure of the wound, the use of drainage, the character of sutures, dressings, etc. It is true that the mortality was still large, which has been so extraordinarily lessened by modern aseptic methods, the chief of which has been the making and maintaining of a wound free from septic infection.

Our profession has been and is justly a very conservative one, and, as a rule, new teaching, no matter how scientific the demonstration, has ever encountered adverse criticism. When I was a pupil of Mr. Lister, in Edinburgh, in 1870, he had a following of scarcely a half dozen pupils, and not a single professor but looked upon his methods with distrust and criticism. My own was the first case of ovariotomy with successful issue in Cambridge, and this as late as 1872, and even this did not meet the approval of my seniors, who declared it unfortunate, lest a number of fatal cases should result from the overweening enthusiasm of a young devotee to a new faith. About this date I found it difficult to obtain the presence even of a physician at my first operation, deliberately planned for the cure of hernia, lest it might be construed into a quasi-approval of that which was necessarily looked upon as a most dangerous operation.

In 1880, when I exhibited to a medical society the specimen of my first resection of the pylorus for cancer, it was met with universal criticism, as beyond the pale of legitimate surgery. My first intercurrent operation for appendicitis was in December, 1886. This was upon Dr. S. N———, to whom was due, quite as much as to myself, the credit of working out the problem, with the deduction that the danger to life would be sufficiently less by operating between the attacks to warrant the operation upon an individual when in a fair state of health. The problem was then a new one and chanced to be the first operation of the kind reported. The danger was generally considered too great to warrant the approval of surgical intervention.

The removal of a biliary calculus from the common duct with immediate suture, followed by easy recovery, October 26, 1889, the first case of this character on record, was criticised as a surgical improbability, although attested by several reputable surgeons who assisted me in the operation. These instances are cited to show the difficulties encountered by pioneers in that which is now considered the every-day work of hundreds of surgeons. It is said that the adventurous innovator of to-day in new fields of research becomes the conservative of to-morrow. Different periods of life have doubtless much to do in bringing about such changes of opinion. However, it is wise to consider, in some directions at least, if the pendulum of surgical opinion may not have swung already too far away from the central truth. It may be well to inquire, if we have not too many surgeons, unless indeed they are better ones, and if the training and preparation for this special work should not be more thorough and critical, since the surgeon should be the good physician and something more. A special training in pathology, bacteriology, a familiarity with anatomy that must ever be an unfaltering guide, and in addition to all, should not the surgeon be the mechanic, artisan, and artist—rare gifts, especially molded to fitness by long years of training!

In conclusion, we may summarize the contribution of gynecology to surgery as primarily the entire domain of pelvic, abdominal, and intestinal surgery. Gynecology, which only a quarter of a century ago was looked upon with disfavor and criticism by surgeons who stigmatized it as the "art of puttering," has become the chief cornerstone in the new edifice dedicated to surgery. Its contributions indirectly benefit every unfortunate sufferer from accident or injury, until indeed it is itself lost in the common weal to humanity and bids fair in the future to be relegated to the past simply as a name, a sort of structural hypothesis, upon the scaffolding of which, one series of earnest workers labored, until they met and joined hands with other zealous rivals, in giving to the twentieth century the surgery of to-day, a sure Art, well builded upon a well-established science.

A CASE OF LEPROSY—A CASE OF MULTIPLE NEVUS PIGMENTOSUS.*

BURNSIDE FOSTER, M.D.
CLINICAL PROFESSOR OF DERMATOLOGY, UNIVERSITY OF MINNESOTA.
ST. PAUL, MINN.

The following case was seen in consultation with Dr. E. Boeckmann, March 13, 1901. The patient, J. J., 20 years of age, was born in Minnesota and has never been out of the state. His father, mother, two sisters and one brother are living and well. The other brother, older than this patient, died in May, 1898, of leprosy, from which he had suffered for about eight years. In infancy this brother had been nursed by a woman who had two brothers, both of whom were lepers and were known to be such in that community. It should be stated that the father of my patient came from a leprous district in Norway forty years ago, but that there is no leprosy in the family history. The mother was born in Minnesota.

---

* Read at the Fifty-second Annual Meeting of the American Medical Association, in the Section on Cutaneous Medicine and Surgery, and approved for publication by the Executive Committee of the Section: W. T. Corlett, L. Duncan Bulkley and W. L. Baum.

The patient presented the ordinary type of anesthetic leprosy, there being eruptions scattered about on different parts of the body. There was, however, a distinct tuber on the right wrist; there was marked thickening of the ulnar nerve on both sides, and numerous areas of marked anesthesia on different parts of the body. The patient had lost a great deal of hair and his eyebrows had nearly disappeared. He suffered from occasional attacks of fever and acute eruptions. A section cut from a nodule in the skin, which I have here for your inspection, shows numerous leprous bacilli. This case is probably an instance of the anesthetic form of leprosy, which, as is so commonly the case among the lepers in this part of the world at least, is becoming tuberous. I regret very much that I have not been able to present the patient.

My chief reason for reporting this case is that I desire to put it on record as the only case of leprosy known to have been born in the State of Minnesota, or indeed in this part of the country. You are all familiar with the statement, so frequently made, that all the cases of leprosy in the Northwest have had their origin in some leprous district of some other country, and that for some unexplained reason, the disease was never communicated to others here, although there has been abundant opportunity for such communication. This case puts the matter in a new light.

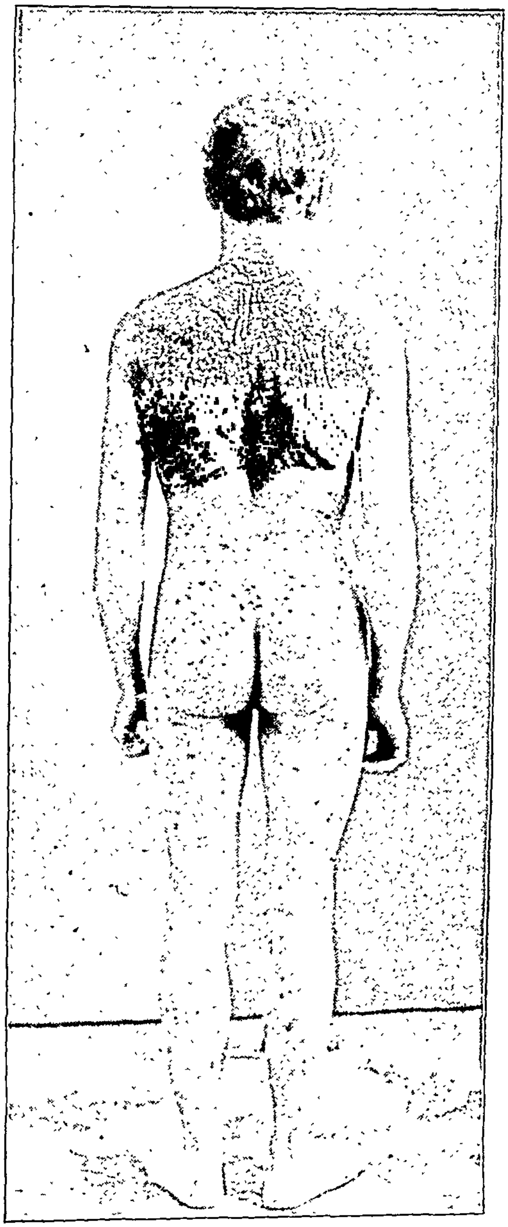
MULTIPLE NEVUS PIGMENTOSUS.

The history of this remarkable case may be told in a few words. N. G., aged 21, was born in Sweden; his family history is negative. He is a strong, well-developed young man, apparently healthy in all respects. The condition here presented existed at birth, and has not altered since, except that the large growth on the back has spread slowly during the last few years. There is a slight secretion from the deeper fissures of this growth and it has an offensive odor. With the exception of the large growth the moles are nearly all smooth and flat, with here and there a growth of hair, notably on the shoulders and right buttock. The question of malignancy must be answered by the future clinical history. The accompanying photograph portrays the appearance better than any description; hence, I shall attempt nothing further in that respect.

The *microscopic report* was made by Dr. J. C. Johnston,[1] from sections submitted taken from the large growth between the shoulders. Hematoxylin alone was used in staining.

Unna[2] has made a thorough investigation of these growths; so thorough, in fact, that it only remains for later investigators to confirm or disprove his findings on minor points. The tumor in question belongs to his class of "soft moles," which are carcinomata, and not endotheliomata, as claimed by Von Recklinghausen; these are developed, according to Cohnheim's theory, from epithelial cell nests, detached from the epidermis in fetal or early life. In many places in these sections connections can be traced between the cell masses and the covering epidermis, there being, apparently, no basement membrane.

The epithelium is not, as a rule, greatly thickened, although there is some increase in all its layers, but the rete pegs are enormously prolonged and form an anastomosing network. The basal layer is deeply pigmented in certain areas, however, not uniformly. In the meshes of the network and in the papillary body generally, are seen the rounded, snared-off masses of cells. Their borders are clearly demarcated, generally by connective tissue. The cells show oval, vesicular, deeply staining nuclei, their contours being made out with great difficulty. Further down in the cutis are seen columns of epithelial cells, oftenest horizontal, between the connective tissue bundles. The cells are closely packed; their nuclei are smaller, more elongated and less vesicular. More deeply, but still in the cutis, the cells are arranged in loose masses, more widely separated from each other, their outlines more clear and the nuclei larger than in any other situation. The appearances here strongly suggest a malignant carcinoma, except that there is no mitosis. Pigment is irregularly scattered through the cell masses and cords lying within and without the tumor elements. The appearance in the former case is often that of a nucleated clump of pigment granules. Vacuolation of the nucleus is frequently apparent, both in the new growth and in the epidermis.



---

[1] Jour. Cutaneous and G.-U. Dis., March, 1899.

[2] Histopathology, p. 1129.

In the cutis the lymph spaces are enormously dilated, but there is no proliferation of the lining endothelium. There is considerable proliferation of connective tissue cells. Careful search failed to show any trace of coil-glands or ducts; here and there, however, attached by solid cords to the surface, were groups having the structure of sebaceous glands, evidently tumor cells pursuing their physiologic course. In this tumor there is both epithelioma and acanthosis, i, e., epithelial proliferation with and without fibrillation, the latter, of course, occurring in the epidermic meshwork.

LUPUS VULGARIS?

I will ask you to help me make a diagnosis in the following case. The patient is 27 years of age, apparently perfectly sound, but for the cutaneous trouble, in physique is almost a giant; he is an operator with a publishing company here. At the age of 3 he began to have ulcers and sores on his body, which have never healed. They have pursued a varying course, sometimes the ulceration has been quite deep. When I first saw him it was for an ulceration on the wrist. There was not very much discharge, but there were two or three jelly-like nodules, which resembled lupus vulgaris. Some nine years ago this young man was treated with tuberculin and the eruption entirely disappeared, but it returned in about six weeks. My first thought, toward which I am still inclined, was, that this is a case of lupus vulgaris and lupus erythematous combined. I want you to note particularly the character of the scar on the wrist which, as you observe, is very soft and pliable. This was the result of treatment by superheated air after the Hollander method.

DISCUSSION.

Dr. William Allen Pusey, Chicago—It seems to me this is a case of lupus vulgaris. Dr. Foster is in a better position to offer an opinion about the erythematous element than we are.

In connection with the leper case, I know of one interesting case of leprosy, in regard to development. It was a gentleman in good position who had lived in Chicago most of his life. He lived in New Orleans for two years, under good hygienic conditions. I saw the case several years ago with a typical tubercle of leprosy on his face. After that he went to Dr. Zeisler. He had lived in Illinois all his life except the two years he spent in Louisiana ten years ago.

Dr. Joseph Zeisler, Chicago—I believe with Dr. Foster that this is a very remarkable case. In my recollection of lupus I fail to remember a case where the disease was so remarkably free. It is unique to see a primary affection of the arm. Like Dr. Pusey I am not in a condition to see the erythematous element at present; the lesions are typical lupus.

Dr. Foster—How about the scar?

Dr. Zeisler—I should say it was an unusually excellent scar for lupus.

Dr. Foster—My diagnosis of erythema was from the scar.

Dr. Zeisler—As to treatment, I should use surgical means—cauterize each individual lesion.

Dr. Douglass W. Montgomery, San Francisco—This I believe to be a case of lupus vulgaris. In regard to the nevus I should think that a pigmented sarcoma had developed from the nevus.

The case of leprosy is to me the most interesting of the three. The development of leprosy in this country is quite an important question, for it seems to be capable of developing over quite a large section of the country. We have always with us in California, and in San Francisco particularly, a great number of lepers, who are almost all immigrants, however, and it is very rare to find an instance of leprosy that has developed on the Pacific Coast. I have had two cases that could be said to have developed on what is called the Pacific Coast. A third case that I thought at first had developed there shows the difficulty of obtaining accurate histories. The patient was a physician, a woman, who had typical leprosy. She steadily denied ever having lived in what is called a leprous country and said she had lived in California only, and California can not be called a leper country. That remained as a fixture in my history of the case until some years later I found that her father had lived in Mexico and that she had been brought up there. Here was a patient, who was a physician, who knew about leprosy, who had studied her own case and knew the importance of the history, and yet told me that she had always lived in California and never admitted having lived in a leper country.

Of the two instances where I found leprosy to develop on the Pacific Coast, one was a man from Vermont or Massachusetts who had never been out of the United States except once for a few hours on the Canada Southern railway going West, the only part of that country he had ever visited. It was a long time after first getting his history that I found he had lived in a Chinese railroad camp, and I have no doubt that he then contracted the disease. Another instance was a woman born in Ireland. She came to New York and afterwards to San Francisco. Her husband was born in Ireland, had lived in Ireland, Boston and San Francisco and nowhere else. Their children were all born in San Francisco. The woman developed eruptions and when I saw her she was in the full bloom of tubercular leprosy. She denied any intercourse with lepers and denied knowing anything about leprosy, and denied association with Chinese. I found out afterwards that she had had for years in her house, as a boarder, a well-known leper, an American who had acquired leprosy in Hawaii. These instances show the difficulty of getting at the source of contagion. These are the only instances I have ever found of leprosy developing on the Pacific Coast, but that it does develop there is a very important finding.

Dr. W. T. Corlett, Cleveland—In regard to the first case, I agree with those who consider it a peculiar case of lupus vulgaris. I do not, however, see any erythematous element in it. The scar is very peculiar. I have in mind a case of symmetrically distributed eruption leaving a scar similar to this, which was the result of syphilis.

In regard to the nevus, it is a very striking case and I quite agree with Dr. Foster that it is at the present time a case of very marked nevus which will probably result in sarcomatous changes later on.

In regard to the case of leprosy reported by Dr. Foster, about three or four years ago there was reported before this Association two cases of leprosy occurring in the vicinity of Columbus, Ohio. I think in Dr. Morrow's article in the "Twentieth Century" these cases are regarded as leprosy. I have seen the cases and after careful consideration must differ from his diagnosis. If they be cases of leprosy they are ones which have developed in the State of Ohio, the patients never having left the state. The father had some mysterious eruption, which seems to give more direct history of syphilis than anything else. The only time he left the State of Ohio was during the war of the rebellion, when he was in the Southern states. I do not report these as cases of leprosy, for I think they are a peculiar form of syringomyelia, closely simulating the lesions of lepra.

Dr. L. Duncan Bulkley, New York City—I dislike to connect lupus vulgaris and lupus erythematosis in any way; for, while the nodules of lupus vulgaris have sometimes developed in the lesions of lupus erythematosis, there is in reality no connection or relation between the two diseases. In the present instance I should regard the whole process as that of lupus vulgaris, and think the scarring is quite compatible with this diagnosis; there are certainly some quite characteristic nodules of lupus vulgaris here and there.

In regard to the nevus, I quite agree that there is danger of the development of sarcoma. I believe that this will occur if he lives long enough.

As to the question of leprosy developing outside of leprous countries, there are enough cases now known to have originated in the United States to make it certain that this may happen. The subject was pretty well thrashed out last year at Atlantic City. I have seen at least two such sporadic cases in New York City, and others have seen similar cases, where the patient had not been in a leprous country and no source of infection could be traced; these cases are, of course, very rare.

Dr. Schuler, Pittsburg—I only wish to speak of the migration of patients with leprosy. A case came under my care some years ago, of which I was perfectly ignorant at the time, but after looking it over I made up my mind that it was a case of tubercular leprosy. As soon as I intimated to the lady what was the matter with her she immediately left me and put herself in the hands of some other person, and continued passing from one to another until she landed in Johns Hopkins Hospital, where she died about two years ago. When I was trying to elucidate where she had lived and how she came by the leprosy, she denied ever having been out of the states of Pennsylvania and Ohio, but when she came near to death she told the rest of her history; that she had spent several years in the West Indies, and no doubt from that source she contracted her leprosy. I wanted to speak of the difficulty of getting a truthful history that you can trace back to a possible origin.

Dr. William Frick, Kansas City—All seem to agree that this is a case of lupus vulgaris, and I did hope that the gentlemen would speak of the treatment by *x*-rays. I have had a case which was treated that way and with marked benefit.

I believe I have at present a case of leprosy in Kansas City and it has developed in the United States. The woman was born in Ireland, came very early to the United States, went around from one place to another, including Vicksburg, and for several years has been in Kansas City. She has had the disease for five years. It is principally in the face, with some nodules on the back. I have not been able to corroborate the diagnosis, but the clinical appearance seems to be that of tubercular leprosy.

Dr. Burnside Foster, in reply—I have been well aware of the fact that this was a case of lupus vulgaris, but not a typical one; and I had thought, on account of the appearance presented by the scars, that this might possibly be one of those cases which we sometimes see where lupus vulgaris and lupus erythematosus co-existed.

REPORT OF A CASE OF EPIDERMOLYSIS BULLOSA HEREDITARIA.[*]

L. E. SCHMIDT, M.S., M.D.
CHICAGO.

On account of the comparative infrequency of these cases, but not for any unusual circumstances in connection with it, the case is reported. W. Beatty, in 1897, gave a most complete review of the cases and literature up to that time. Rona, in 1899, was able to collect but 18 cases in the literature.

As in one case of Dr. Elliot, we find from the history that apparently this affection originated in the patient and was not inherited. In regard to this we know that there must be a starting point, and should there not be any hereditary influence in this case we can not point out why the boy is affected, as the clinical history does not differ from any one of those where we know an hereditary influence is present. Nevertheless, some authorities persist in calling it an hereditary disease.

In my case from its inception the second week after birth the parents believed that traumatism played a rôle in the causation of the bullæ. Nevertheless, after the greatest of care, but *especially after the boy commenced* to walk, the efflorescences continued to appear. The course in all these years has been about the same, neither does it vary as to the time of year.

As has been noticed by Elliot and others, the lesions do not leave any pigmentation, as we find so commonly among bullous eruptions. In these cases epidermal cysts, especially noted by Rona, are frequently seen after a bulla has healed, and these in turn quickly disappear and leave but a smooth, glossy, bright-red surface with the creases of the skin absent.

Edwin B.; age 9 years; presented himself for examination April 15, 1899.

Anamnesis.—Both the father and mother denied any hereditary nervous or blood diseases. All that could be ascertained was that their relatives had never been affected by any other than the ordinary diseases. The father is the third in a family of five, and was married at the age of 24 years. The mother is the fourth in a family of seven, and was married at the age of 23 years.

At present (June 1, 1901), they have been married thirteen years, and previously and since then have never been treated for any disease. Both parents regard themselves as perfectly well, although the mother for some years past has irregularities with her menstruations. Beyond this, nothing further can be elicited.

Two healthy boys, the second twenty-three months previous to the one in view, were born. This one was in all respects a normal labor, no forceps or other instrumentation required. Two years later, without any apparent cause, a miscarriage in the beginning of the fourth month occurred. The fourth and last boy was born four years ago. The three other boys seem to be perfectly well. They have had the ordinary diseases of childhood.

The boy under consideration was under 9 years of age; he was never seriously sick, although had measles and whooping-cough some years ago. At time of birth the patient was regarded as normal. No eruption on skin was noticed. Not until about the end of the second week, then commencing in the soles of the feet, just around the heels especially of both feet "water blisters," about the size of a split-pea, made their appearance. These were opened and treated with dusting powder. About the third month, small, regular, from pinhead to size of Lima bean, blisters appeared at irregular intervals on the dorsal surface of the hands and fingers. When he became old enough to walk, which was the usual time, bullæ up to the size of a large thumb-nail began to show themselves around the anterior surface of the knee, around the ankles, apparently especially over tendo Achilles. Beginning at the time, hemp-sized and small vesicles appeared on the dorsal surface of toes and both feet. Likewise bullæ about the elbow, especially over extensor surfaces, commenced to appear.

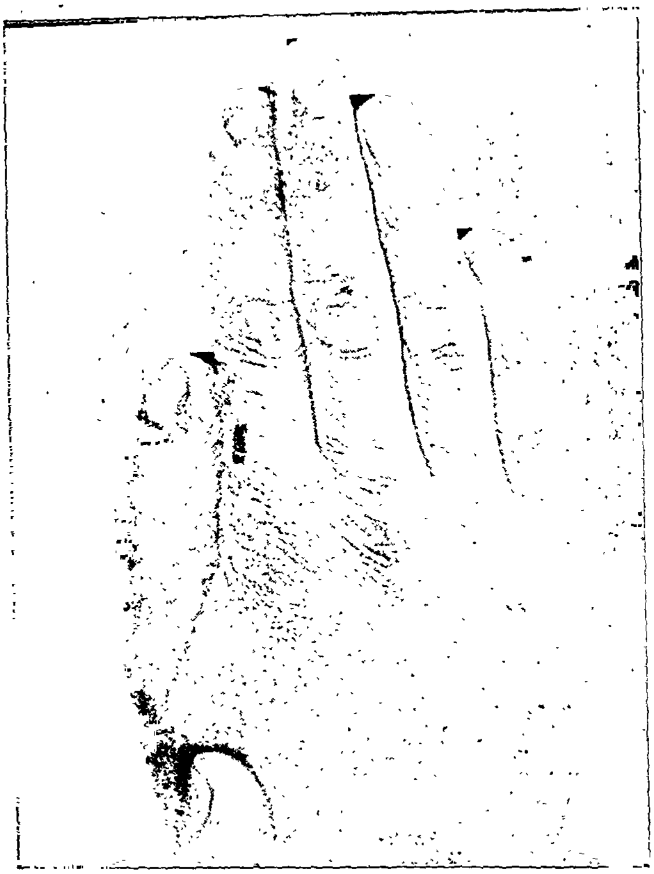
Apparently all these became more exaggerated since patient is able to walk and since he is open to traumatism; that is, these blisters came with more frequency, and usually became of quite large size. His mother states that the larger number of these blisters broke usually shortly after their appearance, and remaining contents would dry and in several days only the outer border of a blister would remain. The contents were usually clear, light yellow in color and slightly tenacious. But rarely would the contents become turbid or milky in appearance. If so, the parts became painful and swollen. It is only during the past four years that the contents of some bullæ occasionally become dark, bluish-purple in color. Both the nails of fingers and toes are affected and have been so as long as the mother can recall. Occasionally small blisters appeared in the external ears.

---

[*] Read at the Fifty-second Annual Meeting of the American Medical Association, in the *Section on* Cutaneous Medicine and Surgery, and approved for publication by the Executive Committee of the *Section*: W. T. Corlett, L. Duncan Bulkley and W. L. Baum.

I have had the boy under observation for over two years. During this time repeated acute attacks of inguinal and axillary adenitis occurred. After a bulla became infected the corresponding glands would often become painful and greatly swollen almost within twenty-four hours. On physical examination of heart I have occasionally heard a hemic murmur. During this time he has had a bronchitis.

One year ago he complained of severe earache. Dr. Holinger examined him and found a small vesicle at border of membrane. As soon as this disappeared the pain ceased.



May 10, 1901.

During this time he occasionally had some unusual appearances in his case. Several times areas the size of silver 50-cent pieces would become red and itchy, and in a few days scaly. These would be over the lower dorsal vertebræ, exactly in the median line. Besides small vesicles, which would become hemorrhagic, appeared in mucous membrane of tongue and buccal surfaces. Patient would not notice them until he was made aware of their presence.

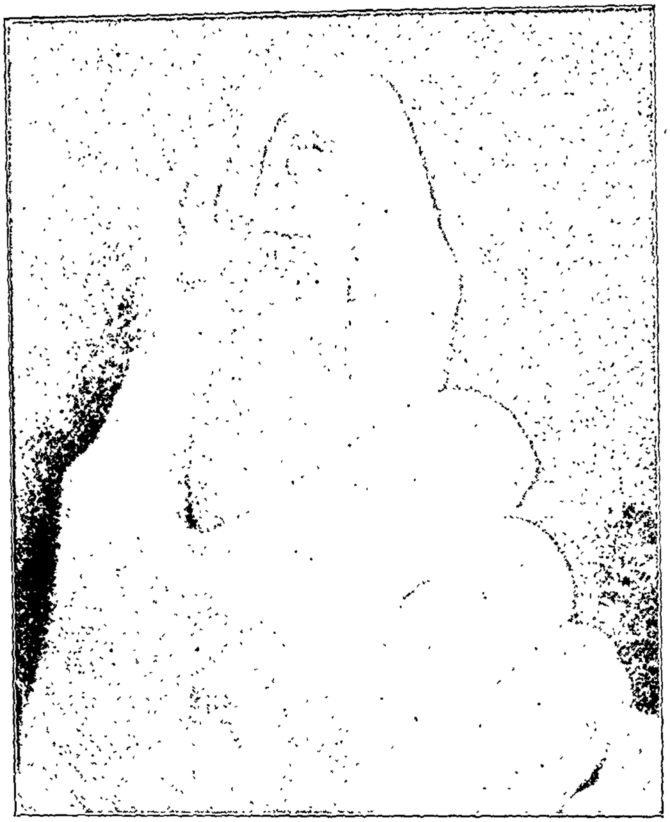
He can play baseball when hands are in fair condition without causing new blisters to arise. Whenever a new blister does appear he always claims it follows a blow or fall.

His mother states that he has always been peculiar in regard to his diet. He refuses to take almost all vegetables and fruit.

During this entire time I have given patient tonics of all kinds, especially for long periods some form of iron; now for some time cod-liver oil. The blebs, as a rule, have been treated by allowing them to remain closed, or, if very large, by opening and dressing with some inert antiseptic powder or salves according to the needs. The infected and hemorrhagic bullæ were treated antiseptically. The former often required moist dressing in order to give relief.

For four weeks I have had the patient in the Alexian Brothers' Hospital under close observation. During this time the hands and feet were wrapped in inert powder and absorbent cotton. Patient was not allowed out of bed and the hands could not be used; was dressed daily. With every precaution so that the affected parts were well protected and so they could not be used, the bullæ appeared with apparently the same regularity as if this care had not been taken. The acute swelling of the glands was treated with unguentum, Credé, and in no case did suppuration occur.

April 25, 1899: Blood examination showed hemoglobin, 74 per cent.; leucocyte count gave polymorphonuclear, 73 per cent.; large mononuclear, 6 per cent.; small mononuclear, 18.5 per cent.; eosinophile, 2.5 per cent.



May 15, 1901.

Nov. 10, 1899: A bleb, irregular in shape, about size of a 25-cent piece, completely full, surrounded by a red zone, located on palm of hand. Cleansed and surface made aseptic and sterilized needle attached to Luer syringe was used to aspirate. This turbid thick and grayish colored fluid was transplanted on the ordinary media. Typical growths of the *staphylococcus pyogenes albus* appeared.

March 6, 1901: Patient returned with a large hemorrhagic bleb at the base of the right thumb and palm of the hand, said to have followed a fall upon his hand. The bleb was opened under aseptic precautions and 9 c.c. of hemorrhagic fluid withdrawn. It was centrifugalized and slides made from the sediment stained with methylene blue and Ehrlich's triple-stain. Cultures were made from the freshly withdrawn fluid and also from the aseptically centrifugalized.

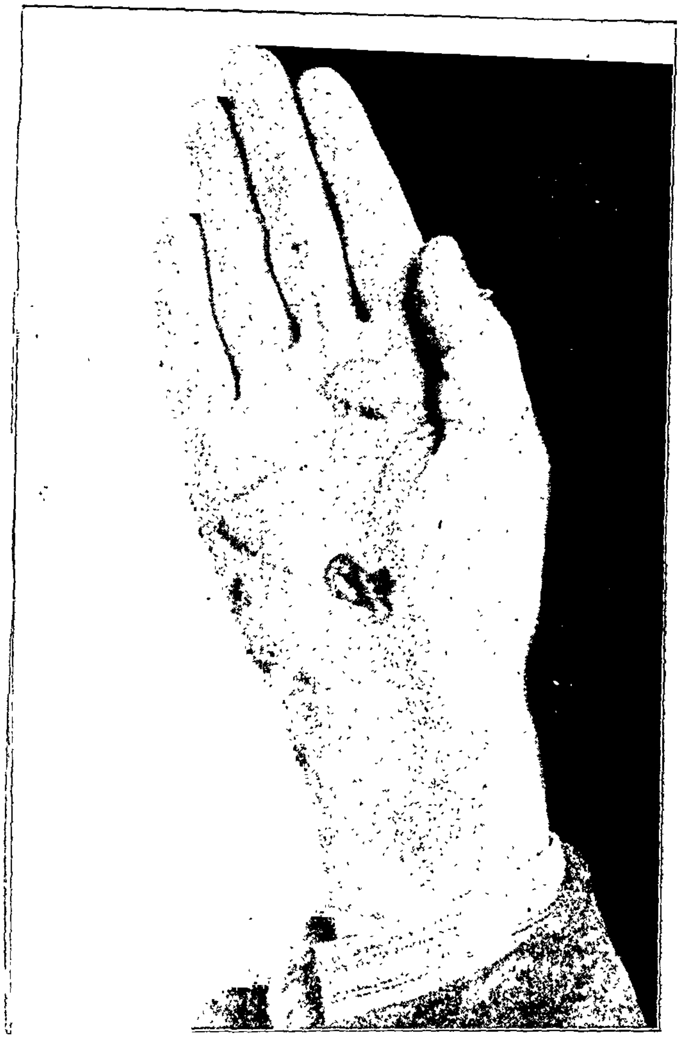
Just below the right patella was another large bulla which was treated in an exactly similar way. The contents were not hemorrhagic, but were perfectly clear.

Four cover-glass stained specimens from sediment of the hemorrhagic fluid showed numerous red blood corpuscles, a few leucocytes, two of which were of the eosinophile variety. No growths on any of the media after 72 hours.

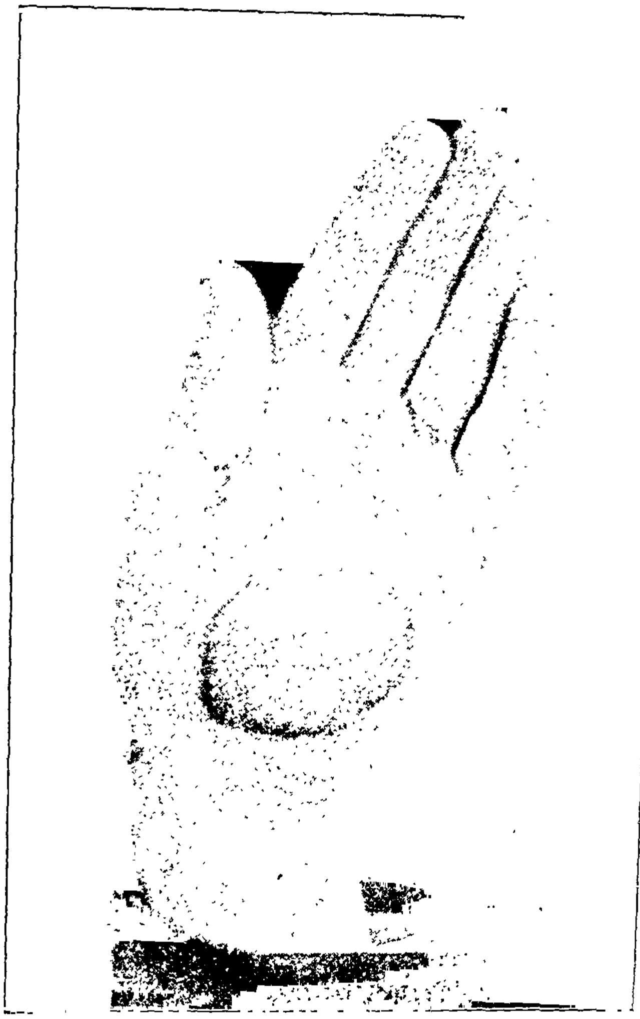
March 27, 1901: Since the preceding visit he has had numerous bullæ on the elbows, forearms and hands, and also on toes and about the ankles and knees. Some of those present are hemorrhagic and others filled with clear fluid. One bulla over the right knee was filled with a turbid fluid. This was aseptically treated and transplantations on ordinary media were made. The staphylococcus pyogenes albus was present in all tubes.

Blood taken from ear showed 71 per cent. of hemoglobin. The leucocyte count showed: Polymorphonuclear, 74 per cent.; large mononuclear, 7 per cent.; small mononuclear, 16 per cent.; eosinophiles, 3 per cent.

April 5, 1901: The condition of patient about the same. Bullæ have come and gone. The contents of several were again examined microscopically. Numerous leucocytes were present and the large number showed no abnormal conditions, but they varied from this to an advanced stage of degeneration. Some were vacuolated and had fragmented nuclei. The red cells appeared smaller than those from the general circulation. Besides, transplantations were made, all without showing any growth.



May 23, 1901.



May 23, 1901.

Analysis showed the urine clear, acid, with sp. gr. 1021; no albumin; no sugar; trace of indican; Diazo-reaction negative; urea, 1.7 per cent.; microscopic examination was negative.

During the entire time that I have had the patient under observation I have made repeated examinations of blood and contents of the various kinds of blebs, and all with the same findings. I could see no change in the course, that is, no decrease or increase in the number of blebs during the different seasons of the year. All the functions of the body seemed to be normal. The skin appeared to act freely at all times, and at no time did he complain of excessive sweating of any particular part. Bulla filled with clear fluid, size of a split pea, located about left elbow, involving an area that had never been previously affected, was removed with ethyl chlorid, incising one-eighth of an inch from the efflorescence. Another, considerably larger, filled with hemorrhagic fluid from about the wrist removed under cocain infiltrations. Besides this other parts, including the epidermal cysts, were removed without any anesthesia. All these specimens were treated alike, hardened in weak, then absolute alcohol, mostly all prepared by the celloidin method, but some were mounted in paraffin. The ordinary staining methods were used and Zeiss microscope and lens used for their examination.

Repeated blood examination showed a variation of hemoglobin from 71 to 83 per cent., going up and down in percentage strength. In the leucocyte count we also see variations: Polymorphonuclear, 73 to 75 per cent.; large mononuclear, 5 to 6.5 per cent.; small monuclear, 16 to 18.5 per cent.; eosinophile, 2 to 3 per cent. Continued bacteriological examination of the contents of the clear and also of the hemorrhagic bullæ showed absence of all bacteria. In those that were infected I have found the staphylococcus pyogenes albus.

Centrifugalizing the contents of hemorrhagic bullæ, all elements of the blood have been found. The larger number of leucocytes showed degenerative processes. Some were vacuolated and also had fragmented nuclei. The red cells appeared smaller than those of the general circulation.

Urinary examinations were negative to all pathological conditions.

For histological study excisions from healthy to frequently affected parts were examined.

HISTOPATHOLOGY.

In the strata spinosum and strata basale in all the specimens examined we find marked changes. Practically the adjacent cells of these layers show varying cellular destruction. Cells adjoining each other often show great contrast; one may be scarcely involved and the other may be the seat of greatest degeneration. This change involved the cell and its contents, yet no definite relation from below upward could be noticed, nevertheless we see that in the interpapillary changes we find the greatest destruction. In examining a bulla we can see how these affected cells, for the greater part, form the outer wall of the bulla, but few cells remain attached to the papillæ, and these, for the most part, show but little degenerative changes.

At a point where the layers of the bullæ again come together these changes were noticed. In some sections the process apparently stopped suddenly and in others the changes in the cells gradually changed to the normal condition.

The contents of the bullæ showed differences. In some, fibrinization had occurred—in those of several days' standing, also in those that were sanguinous. For the greater part the leucocytes that were present had undergone degenerative changes.

The greater number of blood-vessels showed dilatation, and in addition an infiltration about the same. The character of the latter were such that they were most markedly present in the older lesions and scarcely, or not at all to be noticed in lesions that were excised from areas that had never been previously affected.

In all we find a more or less serous transudate about the immediately affected parts. Whenever this fluid reaches these weakened areas of epithelial cells we get a separation of the same, and is the beginning of a bulla. It would seem as if this disease is non-inflammatory, only becoming so when it has reached the chronic state.

What the primary cause for the degenerative changes in the basal layer and the consecutive flow of serum is we can not explain. It must be some peculiar condition of the skin inherent in these unfortunate individuals.

Status Praesens.—Patient is of average size, although muscular development apparently below average. His general health appears to be good. Skin is somewhat flabby and general color seems to be slightly pale. He exercises the same as his playmates, but he is easily hurt, i. e., blebs arise and give cause for pain, especially if they become infected. In his school work he is as far advanced as those of his age. His skin is active, perspires freely, and apparently not unusually from any special area.

Irregularly distributed over the surface of tongue, more towards the median line and extending posteriorly to the circumvallate papillæ, from pinhead to one-half hemp-seed sized vesicles, some filled with a clear and others with hemorrhagic fluid. A few of them are so situated that the teeth could not have caused any traumatism. On the buccal mucous membrane on a level where the teeth touch, and opposite decayed teeth, are elongated vesicles filled with hemorrhagic fluid. About these parts a light leukoplakia exists, showing that possibly similar eruptions have preceded it.

On the lower lip, just to the right of the median line, the signs of an old 5-cent piece sized bulla partly extending over the skin.

On the tips of both ears irregular in outline, the border raised and represented by an epithelial layer passing into the normal *niveau*. Within this outline the skin is of a slightly redder hue. Within can be seen some parts that have apparently not been affected. These parts as well as all the others are normal to the different sensations.

Exactly over the tenth dorsal spinous process a perfectly round flushed area, silver-dollar in size. It has given him a slight sensation of warmth and itchiness. Over the upper lumbar vertebræ and in the median line an area somewhat smaller in size, color not quite so bright and the surface covered with very minute scales. This has been present some ten days. These have never reached the stage of bullæ, nor have any bullæ ever been noticed on the back.

Thumb-nail of right hand is about to become detached. It is raised, especially at base, and here, too, are transverse striations. The whole is very opaque and slightly movable. On raising a very distorted nail, with rough surface and with no free edge, is to be made out. On the flexor surface over the second phalanx a 10-cent piece sized bulla filled with clear fluid. About the nail and extending over the greater part of the dorsal surface of thumb, is scaly and of a dark-red color.

Now, over the metacarpal-phalangeal joints a few small vesicles. Interspersed we find pinhead sized white-capped elevations or epidermal cysts, arranged apparently usually in circles, which probably correspond to the outline of some previous existing bullæ.

The entire palm of hand covered with bullous eruptions, several bulla having come together. Contents is dark-purplish in color. About the wrist and extending partly up the extensor surface of forearm a similar appearance to that over the dorsal surface of the hand. Over the extensor surface of the elbow is a bulla one and one-half inches in diameter, comparatively well filled, slightly flabby with clear, semi-fluid liquid.

The nails of the thumb, middle and small finger are similarly affected as on the right side, except that a whitlow exists about the index finger-nail, it having followed a bulla. The palm of hand and dorsum as well as wrists and elbow showed a few bullæ, epidermal cysts and also red and scaly patches.

Nails of toes of right foot are all irregular, small, surface rough and apparently poorly nourished. Over dorsal surfaces of all the toes a reddish scaly condition and a few small vesicles present; similarly on the toes of left side. Never any bullæ on soles of feet, only occasionally on the dorsal surfaces, consequently only normal skin. About the malleoli and over the lower part of the tendo Achilles we find a few blebs and remains of old ones. No signs over tibiæ of any previous affections, but at present over both knee caps, palm-sized, flabby bullæ. About these scaly and discolored skin.

The hands show no signs of any cyanosis or edema. The shape appears to be normal, except when bullæ are present. The palms and dorsal creases are present when not temporarily affected by bullæ. Especially on the extensor surfaces of the extremities where bullous eruptions have frequently existed we find the skin glossy, tense, and the normal striæ of the skin lost or all the appearances of atrophy present. In these areas we find these epidermic cysts. These apparently go and come without leaving any permanent macroscopic changes.

I have attempted with heat, chemicals, and mechanical means to cause bullæ, but without avail. A slight redness would appear, but only of passing moment.

Of late there seems to be a tendency among some authorities, among whom we find Hallopeau, to bring all these cases under one class, yet to recognize different varieties. All varieties have some things in common. We find, 1, that shortly after birth or usually at latest in early youth, there is a tendency for traumatic bullous eruptions; 2, that similar areas are affected; 3, that it is hereditary; 4, that the general health is intact; 5, that the course is chronic and remains uninfluenced by therapy.

Now, the dystrophic form of Hallopeau includes the case which I report. Because, in addition, it has consecutive atrophy of the skin, epidermal cysts and distortion of the nails. Those cases that belong to the simple variety can not have any one of these changes present.

That these types exist we must admit. Certainly the clinical appearances are very marked. Without doubt these differences are so great that we must admit of the possibility of varieties. But it is asked: Why make such classifications? Have we not various diseases in which one or more clinical symptoms are absent and yet call one and all the same? No two cases of different types in the same family have yet been reported. This would almost certainly be a connecting link between the two and to some extent clear the question.

I think that we are still in doubt, and that for the present it will be best not to classify all under one and the same disease.

DISCUSSION.

DR. F. H. MONTGOMERY, *Chicago*—I am *only* sorry Dr. Schmidt can not show the case here. Those of us who have been fortunate enough to see this case have no doubt regarding the correctness of Dr. Schmidt's diagnosis.

DR. M. L. HEIDINGSFELD, *Cincinnati*—The feature which has impressed me most strongly in Dr. Schmidt's interesting paper, is the low percentage of eosinophilia, less than 2 per cent., if I remember rightly. This corresponds to the recent investigations of Bettmann of Heidelberg, who has found an exceedingly low percentage of eosinophilia in epidermolysis bullosa, which is in direct contrast with nearly all other forms of bullous eruption, and what is most interesting, is also in direct contrast with the investigations of nearly all other writers on epidermolysis bullosa, notably with Columbini, who claims an eosinophilia of 14 per cent.

The nature of the bullæ in this disease is also a matter of peculiar interest. It has been noted that sinapisms, in the form of mustard plasters, Spanish-fly, etc., when applied over the predisposed pathological areas, are unattended by vesication or even redness, while on the other hand, these symptoms are promptly induced over normal tissues elsewhere, which from the very nature of the disease, is the converse of the anticipated. Subcutaneous injection of normal salt solution, over the pathological areas, has been followed by the formation of bullæ which have the same appearance and pursue the same course, as those of spontaneous nature. From this, the deduction has been drawn, that the essential factor underlying this peculiar condition, is an undue relaxation of the areolar connective tissue, which readily permits and favorably prolongs an exudation.

DR. LOUIS E. SCHMIDT, *in reply*—This case has been different from the cases reported in the literature. I know in regard to some of the findings, especially as far as being able to raise bullæ by artificial means and in blood examinations, they differ very markedly from some of the authorities. The microscopic findings are practically the same as those of Elliot.

New York State Insane.—Inequalities in county statistics of the insane are pointed out by the lay press without assigning any causes for the discrepancies. Thus Ontario county, with 49,000 inhabitants, has 185 insane, while Clinton, with 47,000, has but 88. Rensselaer, with 121,000, has 527 insane, while Oneida, with 133,000, has but 438. Ulster, with 88,000, has 265 insane, while Duchess, with 81,000, has but 360, and St. Lawrence, with 89,000, has 209. Orange county, with 103,000, has 357 insane, while Westchester, with practically the same population as Orange, has 500 insane.

PROTRACTED INFLUENZAL PNEUMONIA IN INFANCY.*

FRANK X. WALLS, M.D.
PROFESSOR OF CLINICAL PEDIATRICS, NORTHWESTERN UNIVERSITY.
CHICAGO.

While no period of life is exempt from influenza, it has been observed, during the pandemics of grip that have encircled the world, that infants are in a high degree immune from this scourge. During the recent epidemic of December and January, 1900 and 1901, I had under my observation, at the one time and in the same institution, four infants suffering from protracted pneumonia of influenzal origin, which, I trust, are of sufficient interest to present their histories and exhibit some pathologic specimens.

It is not my wish to convey the impression that grip in infants usually runs such a protracted course as the cases I present. During this period of life, grip is as protean in all its characteristics as in other life epochs. None the less the simultaneous occurrence of four cases in an institution that shelters sixty to seventy-five babies argues for the great frequency of severe and protracted forms, if infants be afflicted with influenza.

Etiology.—These four infants were fed exclusively on artificial food at the time they contracted the grip, and two of them had been nourished in this manner since birth. This is in accord with the observation that nursing children are almost absolutely immune, even though their mothers be seriously stricken with the grip. This immunity is explained by assuming that a potent antitoxin is eliminated in the maternal milk. Infants artificially fed are more susceptible than babies at their mother's breast, but are less susceptible than adults. Comby estimated that the morbidity among children in Paris during the pandemic of 1889 and 1890, was 40 per cent., and among adults was 60 per cent. We may state that the influenzal sick-rate, which is nil in young infants, progresses and regularly increases up to adult life. The youngest child that Comby reports with the grip was 17 days old, and he saw three nurslings contract the grip while nursing their sick mothers. This latter observation is quite exceptional. Relapses among children are not rare, but second attacks, during the same epidemic, are exceptional. The contagiousness of influenza is very great, and, particularly in institutions caring for a number of children, the afflicted infants should be isolated.

Symptomatology.—The onset, in these cases of protracted grip-pneumonia, was rather precipitate, and presented the clinic picture of a more or less severe gastrointestinal infection, to which, in a few days, symptoms of involvement of the respiratory tract were added. Convulsions were not present, neither were there any pronounced nervous symptoms, such as stupor, chill, etc., though some irritability or restlessness was early present.

Usually the first symptoms observed would be that the child refused its food, or, if it had taken some, would vomit. It would be cross and fretful, would have a high fever, the breathing would become fast, then hurried and jerky. Cough, at first short and occupying a single expiration, would increase in intensity until it might be paroxysmal and continuous as in pertussis. The bowels were usually constipated and a considerable accumulation of gas in the stomach and intestines was frequent. The tongue usually was red and dry or coated with a moist whitish fur, and the pharynx mildly injected.

---

* Read at the Fifty-second Annual Meeting of the American Medical Association, in the Section on Diseases of Children, and approved for publication by the Executive Committee of the Section: H. E. Tuley, Edwin Rosenthal and Samuel W. Kelley.

The temperature was elevated to a high degree, even early in the disease, and was distinctly irregular and intermittent, pursuing no definite cycle. One of the curves in particular resembles that of a pus infection. This irregularity and intermittency is intensely characteristic of influenzal infection and is in marked contrast to the pulmonary infection with the pneumococcus. The remissions of temperature may resemble the irregular and inverse type, as observed in tuberculosis, or may exhibit such a periodicity as is observed in malaria, and these resemblances are still further approximated by the frequent concomitants of drenching perspiration. The daily difference between maximum and minimum temperature, as exhibited in these charts, is very great, and differs very much from that observed in the vulgar gastro-intestinal infections. It appears to me that these characteristics of the temperature curve, sudden onset, great height, irregularity, and great daily difference are rarely exhibited in other infections in infancy. Hyperpyrexia was several times observed, but was well borne by these infants.

The earliest symptom of respiratory involvement was an acceleration of breathing. The breathing was continuously short, shallow and fast approximating 30 to 40 respirations a minute, with paroxysms when the rapidity would excel 60 to 80 a minute. These paroxysms would continue from a few minutes to an hour, and would be accompanied by a severe degree of cyanosis. More or less coryza was present in all of the cases, while in two cases the nares became intensely inflamed; in these two there was an extension of the inflammation to the middle ear, with rupture of the drum membrane and discharge of muco-pus from the external ear.

Cough was present, but not early. It was sometimes paroxysmal and explosive, suggesting the cough of pertussis. As is the rule in infancy, there was little sputum raised with it and we were content to examine what could be obtained, during a paroxysm of coughing, by placing the infant's face downward and gently slapping it on the back, or removing the mucus from the mouth with the finger. In one case we obtained some sputum by means of the stomach tube that was introduced because of an accompanying gastric disorder. At no time was the sputum rusty or even blood-tinged, but usually consisted of a thick, tenacious, glairy, transparent mucus. The sputum was obtained from all four cases and was examined particularly for the influenza and tubercle bacillus. Smears were made on glass slides and the stains usually employed for tuberculosis were used, but in none of the cases were tubercle bacilli found. For influenza, a weak carbol-fuchsin, or hot, methyl-blue solutions were used and cultures were made on hemoglobin blood serum. Influenza bacilli were present in all cases, a few times, in what seemed to be pure cultures, but usually associated with other bacteria.

The pneumonia was clinically lobar. A large part of one lung was consolidated without intervening aërated portions in the same patch and the remainder of the lung showed evidences of only a diffuse bronchitis. The consolidation was very slow in its development, not being observed until several days, a week or even longer, after the initial symptoms; and when the consolidation was pronounced it gave the characteristic physical signs observed in adults, viz., dulness, bronchial breathing, and bronchophony. Distinct crepitant râles were wanting over the consolidated area, but crepitating, cracking, and mucous râles were very abundant. Small and large mucous râles were diffused over both lungs. Consolidation persisted during the entire course of the pneumonia, and, in the cases that recovered, slowly cleared up, and, within a few weeks after the temperature became normal, the lungs were clear.

The pulse was fast, rather weak, but not distinctive, and corresponded to the intensity of the infection, as measured by the pyrexia, lung-involvement, etc. The pulse-rate varied from 140 to 180. The examination of the heart did not reveal any symptoms of peri-, myo- or endocarditis, but complications on the part of the heart are very frequent during the course of the grip in infants; more particularly are found weakness, dilatation and failure of the right heart. Fluid or fibrinous exudate in the pericardium has been observed in older children and postmortem changes in the myocardium of a degenerate nature are not rare.

The nervous system was signally exempt from any complication in these cases, if we except the early restlessness and irritability, and in one case the slight rigidity of the lower limbs, though many observers have noted convulsions and paralysis from involvement of the central nervous system, and meningitis from influenza is not unknown. Hemorrhage and abscess in the brain, disseminated myelitis, hemorrhagic pachymeningitis and peripheral neuritis have been encountered during the grip.

The urine presented the usual febrile characteristics. It was strongly acid in reaction, of a high specific gravity and contained abundant urates. In only one case was albumin present, and this was two weeks before the fatal termination, when a nephritis developed which became very intense and was in a great measure responsible for the unfavorable termination.

The abdomen was usually distended with gas, at times even considerably, but offered no other abnormal conditions. There was neither rigidity nor tenderness, and the liver and spleen were not palpable. Herpes was observed in one case, but no other skin eruption was noted in these cases. Mention should be made of the profuse perspiration which was present in all of the cases and which is said to be dependent upon an angio-neurosis—a vasomotor paralysis—due to the grip-toxin.

The literature records, as occurring in grip in children ,an exanthema simulating closely either the diffuse punctate erythema of scarlatina, or mayhap the mottled reddish eruption of measles. Sudamina, urticaria, erythema, nodosum, erysipelas, pemphigus and hemorrhages into the skin have been observed, although, as was stated, these eruptions were not present in the cases under consideration. Otitis media appeared in two cases, which is in accord with the known frequency of this disorder complicating inflammations of the upper respiratory tract, particularly during early life. Slight hyperemia alone was observed as regards the ocular complications, though severer disturbances have many times been recorded.

Pathology.—Concerning the pathology of protracted influenzal pneumonia, because of the necessary limits of this paper, only some of the important data will be considered. The anatomical form of protracted grip pneumonia is essentially catarrhal. The pneumonia may occur acutely, suddenly involving a great extent of lung, just as in croupous pneumonia, but in my cases the pulmonary consolidation was slower in its involvement of the lung, but resembled the croupous pneumonia in its lobar distribution. The pneumonias were characteristically desquamative or catarrhal and were accompanied by diffuse inflammation of the fine and larger bronchi. The entire respiratory tract was congested. This was particularly true in the small bronchi, and the mucous membranes were covered with a tenacious mucus. In some of the smaller tubes the entire lumen was choked with muco-pus.

Within the lobules, the alveoli were filled with a cellular exudate made up of pus, desquamated epithelium and a granular debris. Fibrin was conspicuously absent. The alveolar walls were densely infiltrated with round cells, the blood-vessels in the bronchi and interalveolar tissue were engorged, and in one of the specimens they were filled with firm thrombi. This vascular thrombosis, in one of the specimens, had occasioned a small area of necrosis with softening, and from a more extensive thrombosis, a larger area of pulmonary gangrene or abscess might result. The pleural surfaces were smooth and presented no signs of inflammation, though purulent pleurisies are frequently encountered secondary to grip pneumonias.

Pericarditis has been observed and, as a rule, there is a catarrhal inflammation of the mucous membranes of the stomach and bowels. In some cases the lymphoid nodules in the small intestine are swollen, and may even be necrotic and ulcerate. Peritonitis is a rare metastatic complication. The liver may be the seat of abscess formation, though usually the only pathologic alteration in the liver is an albuminous degeneration. The kidneys, in one of the fatal cases, were the seat of an advanced diffuse nephritis with microscopic foci of suppuration. Usually a cloudy degeneration of the tubular epithelium and a slight exudate in the glomeruli, with hyperemia of the tufts, represent the extent of the renal lesions in grip, rather than the severer lesions of necrosis or suppuration. Metastatic processes of a suppurative nature, in the glands, bones or joints, are occasional complications of grip pneumonia, and in the same category might be included thrombo-phlebitis, with phlegmasia alba dolens.

The duration of influenzal pneumonia varies within wide limits. One extreme may be represented by this series of cases, other cases being almost evanescent or diurnal in their duration. The greater number of cases of grip pneumonia probably continue over a space of time that would represent the mean of these extremes. Two of the four cases perfectly recovered, one after twenty-five, the second after forty-one days; two died, one with the lungs in a condition of purulent pneumonia, localized pulmonary abscess and metastatic nephritis; the other, as the immediate result of a complicating infectious disease, with the lung in a state of splenization.

Pulmonary abscess and gangrene are particularly to be feared in these pneumonias, and the probability of their occurrence is enhanced because of the extensive thrombosis of the pulmonary blood-vessels. Complications with abscess or gangrene are almost always fatal. Even after months of protracted pneumonia, a complete restoration to normal pulmonary tissue may occur; or, connective tissue destruction of large areas of lung may result, with perhaps the formation of bronchiectatic cavities that invite secondary infection with pus microbes, leading to suppurative necrosis or ulcerative processes. Tuberculosis is a very common sequel to protracted influenzal pneumonia.

Diagnosis.—In the presence of an influenzal epidemic, with evident grip infection in other members of the household, the probability that a serious illness in an infant was influenza would suggest itself. The following diagnostic features of grip pneumonia would be included: the sudden onset of a sickness, with mild intestinal symptoms and evidences of inflammation of the upper respiratory tract; sharp elevation of temperature and highly irregular course of fever, with the physical signs of a lobar pneumonia, and the demonstration of Pfeiffer's bacillus would render the diagnosis positive.

The differential diagnosis would include particularly gastro-intestinal infections (dietetic or specific, such as typhoid), pneumococcus pneumonia or ordinary broncho-pneumonia, malaria, sepsis and miliary or diffused tuberculosis. In typhoid the onset is more gradual, the temperature-curve more regular and the respiratory symptoms are not so pronounced. The Widal blood test and the Ehrlich urine reaction, the roseola and splenic tumor are wanting in influenza, and the infrequent occurrence of typhoid in infants would weigh against the diagnosis of typhoid.

Gastro-intestinal infections might present considerable difficulty for a few days, but the greater severity of the pulmonary symptoms, the irregular temperature, and the negative result of dietetic treatment, would weigh against it. Grip pneumonia may offer many of the symptoms that occur in malaria. Irregular course of the temperature, that may even be periodic, and the profuse sweats might be accepted as malaria, if a thorough examination were neglected. From malaria the diagnosis would be turned, by the absence of plasmodia in the blood, the absence of splenic tumor and the failure of relief through quinin.

So many of the signs and symptoms of influenza are common to tuberculosis that the greatest difficulty may arise in a differential diagnosis of these conditions. The pulmonary signs, which are of slow evolution and persist longer than lobar pneumonia, with the irregular temperature, the fast pulse, the accelerated respirations with cyanosis, and the profuse sweating, may constitute a clinical picture of tuberculosis. Tuberculosis is difficult to differentiate in these cases and it is only after repeatedly failing to detect the tubercle bacillus and the finding of the Pfeiffer organism that one feels content in excluding tuberculosis. The tuberculin test is rarely employed. In miliary tuberculosis, it is true that tubercle bacilli are rarely found in the sputa, but here the finding of the influenza bacillus, mayhap in pure cultures, would weigh against tuberculosis. The history of an inherited tubercular tendency or possible contact with phthisical individuals would favor a leaning toward tuberculosis, and the absence of such a history would have a negative value.

Prognosis.—In venturing a prognosis we must be extremely guarded. Severe cases might entirely recover under favorable circumstances, but the possibility of imperfect recovery, with lasting pulmonary disease, should be kept in mind. Death, during the height of the disease, may occur from the severity of the intoxication, with extensive pulmonary disease and failure of the right heart. It may occur from influenzal complications in other organs, i. e., kidney, brain, etc., or the lessened resistance consequent upon the grip may permit usually mild infections, such as varicella, to kill, and too, the frequent occurrence of tuberculosis as a sequel to grip must be ever kept in mind.

Treatment.—There is no specific remedy for influenza, and these cases must be treated individually on general principles. Grip cases should be isolated, so far as possible, and this particularly in hospitals and infant asylums. We should select for the little patients a large well-ventilated room, free from noise, and one that is kept moderately warm—80 to 85 degrees F. This is much warmer than advised in ordinary pneumonia. Infants do better if carried about a few hours each day than if permitted to lie all of the time in bed.

Diet is most important and should be nutritious and conform to the digestive capabilities of the infant. Certified milk, meat juice, cereal decoctions, fruit juices and plain water, when properly administered, are usually sufficient. A tepid bath should be given every day. The mouth and nostrils should be given the greatest care, using a gentle alkaline and antiseptic wash several times a day. It is customary and advantageous to relieve the gastro-intestinal tract by a laxative or enema at the onset of the illness. We should avoid the nasty, sweet stuffs commonly given as cough mixtures, for these cause a degree of gastric distress greater than any sedative effect they may have.

Belladonna and nux vomica, given in physiologic doses, probably act better than do other medicines in the average case of infantile pneumonia. They act as general and especially as respiratory stimulants, promote deeper breathing and free the bronchial tubes of considerable mucus; what is of especial value, they keep up the heart strength, which, in infants, is likely to fail, because of the added mechanical work to a heart receiving impoverished and toxic blood. Heart failure, of the right heart particularly, should be guarded against from the beginning, rather than to await the onset of cardiac failure. In the event of impending cardiac failure, in addition to strychnia, we may employ camphor, nitroglycerin, ammonia or its salts, whisky, and the careful administration of digitalis.

The peripheral circulation can be favored by stimulating baths, such as hot mustard baths. Inhalations of hot moist air, plain or medicated, as administered under a tent, may relieve the symptoms of suffocation that supervene so often in infant pneumonias. An infant may be placed in the tent for fifteen to thirty minutes several times a day. Cold applications to the skin frequently act in a very happy manner in cases of threatened suffocation. Dipping the child into a cold and then into a warm bath, followed by brisk friction, acts as a great respiratory and cardiac stimulant.

A cotton jacket around the chest is often grateful to the patient, and I have thought that a calomel plaster —5 per cent. calomel in lanolin—placed over the consolidated lung, favorably influenced the pathologic condition. The temperature should be combated, if the necessity be present, by water, rather than by antipyretic medicines. In some cases these remedies may act in a pleasing fashion, but it is safer to have recourse to hydrotherapy, cold sponging, spraying, baths, friction, or enemata of cold water, not only to reduce the temperature, but to act as general tonics. In protracted cases the bitter tonics and tonic wines, iron, arsenic and cod-liver oil, find their place, and if convalescence be prolonged, a change of residence to a dry, warm, equable climate might be of inestimable benefit.

Case 1.—Anthony F., aged 1 year; weight, 21 pounds 9 ounces.

Dec. 20, 1900: Admitted to asylum; history of having been sick one week. Had poor appetite, with greenish mucous stools three times daily; severe cough and irregular temperature. Examination: Skin pale, sallow and hot; mouth, normal appearance, six incisor teeth; the lymph glands are enlarged universally to a slight degree; over the back of the right lung below the scapula there is an area about two inches in diameter, where signs of pulmonary consolidation were found; left lung presented negative findings, heart normal, abdomen somewhat distended.

December 24: Child has been fretful; poor appetite, stools contained some mucus, severe coughing spells with thick tenacious sputum. Over the right lung, posteriorly from the middle of the scapula to the base of the lung, and extending from the spine into the axilla, resonance is dull, with many râles on auscultation; in the center of this area, bronchial breathing and bronchophony are present. The sputum, examined for tubercle bacilli, was negative, but showed the influenza organism in great numbers. Other bacteria being sparsely met with.

December 29: Pale and much emaciated. The bowel movements have been frequently offensive, with undigested particles. Urine, specific gravity 1010, contained neither albumin nor casts. Cough not so severe. Physical examination of the lungs, same as December 24.

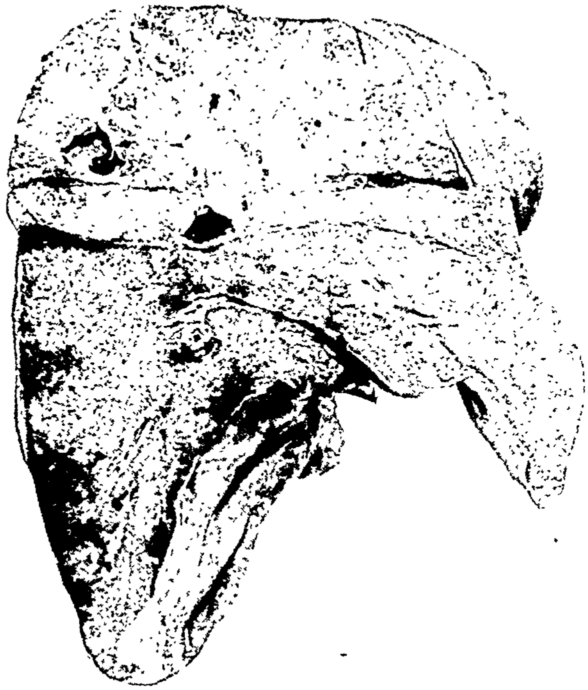

Fig. 1.—Purulent influenzal pneumonia with foci of softening.

Jan. 17, 1901: The appetite has been variable; no vomiting; bowel movements at times contain mucus and undigested masses. Cough, sometimes very severe with little expectoration. Respirations, 50 to 60 a minute, regular and free. Has lost considerable strength and flesh. Physical examination of chest revealed the same physical signs with each examination, that is, evidences of the consolidation of the right lower lobe, a few mucous râles heard here and there over other parts of the chest.

January 31: General condition somewhat improved. Cough not so severe nor frequent; resonance over right lung has cleared up materially since January 21. Respiration is subdued on the right side, with very few râles.

February 15: Varicella. Resonance over the right lung posteriorly is slightly impaired, no râles, respiratory tones are normal.

March 1: General nutrition very much improved, digestion almost normal, no evidence of pulmonary disease, temperature normal, general condition satisfactory.

Case 2.—Annie Sweeney. Aged 1 year, only child of healthy parents, moderately well nourished, reared on mixed feeding, weight 18 pounds.

Jan. 6, 1901. She was observed to be ill, fretful, and crying, refused the breast and bottle altogether, or took but little. Sleep was restless and disturbed; temperature elevated; breathing rapid and interrupted by short cough. Bowels moved four times daily, were dark green with much mucus and offensive odor. Examination: The mouth, tongue and throat were red and dry; there were some small moist râles over the back part of both lungs; abdomen somewhat distended.

January 10: General condition about as above, and on examining the chest, the râles were more numerous and abundant over the back part of both lungs.

January 12: Appetite has not been keen, bowel movements are rather free, but of normal appearance; at times there was considerable distention of abdomen and retching, was relieved by lavage. The attacks of coughing not very severe, but persistent. On examining the chest there was an area over the posterior surface of the left lung, extending from the spine of the scapula to the eleventh rib and from the spine to the posterior axillary region, where there was dulness, bronchial breathing and crepitant râles. Small mucous râles occasionally were heard over the remainder of both lungs. Heart was negative; Traube's space of normal size.

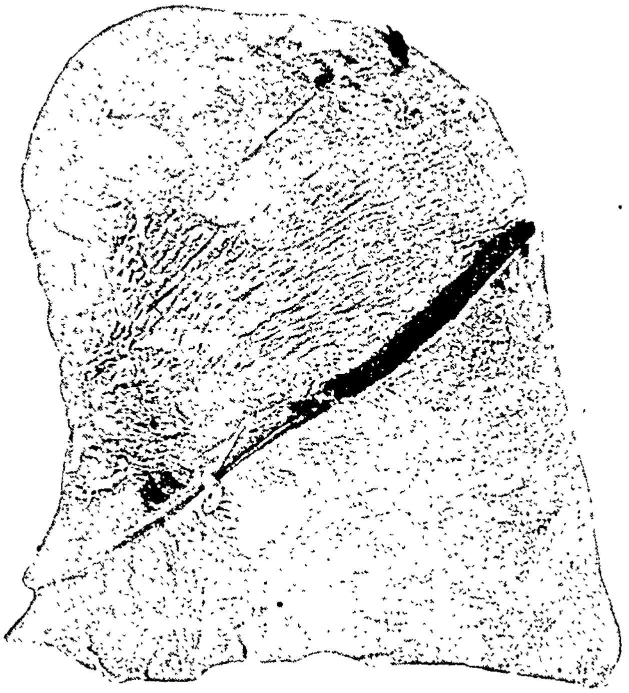

Fig. 2.—Splenization following protracted influenzal pneumonia.

January 22: The symptoms have persisted in much the same manner. The resonance over the entire left lung is impaired and posteriorly, below the spine of the scapula to the base of the lung, the note is almost flat; on auscultation there was bronchial breathing with crepitant râles. Although there was no dislocation of the heart, and Traube's space extended from the sixth to the costal arch, yet because of the irregular temperature and protracted course, a thoracentesis was done but with negative result.

January 25: Same physical signs as January 2, except that the periphery of the area seemed to be clearer.

January 29: Resonance over the left lung is almost normal. Respiratory movements free, and normal in quality, though more frequent than normal. On the left side the respiratory murmur is shallower than on the right and on deep inspiration is accompanied by a few râles. General condition much improved.

January 31: General condition satisfactory, no abnormal thoracic nor abdominal signs.

Case 3.—Mary T., aged 13 months, was fed on human and cow's milk until she was 8 months old. Since then has been nourished on modified cow's milk alone. During her infancy she had several attacks of acute gastro-enteritis, and when six months old she had the measles with broncho-pneumonia.

Jan. 7, 1901: For the past few days she has been out of sorts, with little appetite for food and a considerable elevation of temperature. She had a slight cough and several times, during the day, she had periods of very rapid and shallow respiration, with considerable cyanosis of the face and extremities. Examination showed the child to be fairly well nourished, the skin dry and hot, with no exanthem on the body. The tongue was red and dry, slightly coated; the gums not inflamed, had 8 incisor teeth. Pharynx was moderately injected. Respirations were accelerated, but free; no signs of consolidation of the lungs elicited, but numerous small, moist râles were heard over front and back of both lungs. Heart was rapid, otherwise was negative. Abdomen was slightly distended, no tenderness nor rigidity; liver and spleen were not palpable.

January 12: Respirations frequent and catchy, often interrupted by a short cough; very restless at night. Lower limbs rigid; appetite poor. Over the right side of the chest, from the clavicle to the third rib, were dulness, distant bronchial breathing, bronchophony and crepitant râles. Coarse mucous râles over the rest of lungs.

January 14: Mucous membrane of nose congested with slight muco-purulent discharge. Ears negative; physical signs over the chest same as January 12.

January 18: Symptoms and physical signs remain as above noted. There was also a purulent discharge from both ears. Urine was high-colored, and contained traces of albumin and a few granular casts. Herpes on angle of mouth and alæ nasi.

January 22: Upper lip swollen and excoriated from purulent discharge of nostrils. Urine became gradually less in amount, contained large amount of albumin, and numerous coarse granular casts. From the apex of the right lung anteriorly, to the fourth intercostal space, the signs of pulmonary consolidation persisted, with evidences of a profuse bronchitis. The sputum and nasal secretions were repeatedly examined for tubercle and influenza bacilli with positive results as to the latter. Vomiting, with great restlessness and twitchings and gradual failure of strength, preceded the fatal termination.

Postmortem: The right upper lobe was entirely consolidated and of a uniform, yellowish-gray color. About the middle of the lobe was a focus of softening about the size of a hazelnut, projecting like a blister beyond the level of the lung and containing about a half dram of thick pus. Below this small abscess is an area of caseous necrosis, a half inch in diameter. The color of the cut section of lung was grayish-yellow, almost homogeneous, slightly granular, dry and airless. Irregular areas of emphysema and atelectasis were scattered throughout the remainder of both lungs. Mucous membrane of bronchi was congested, and from the bronchioles could be expressed fine droplets of muco-pus. Scattered through both lungs, particularly at the base, were some small peribronchial nodules of consolidated tissue of a deep-reddish color. Smear and cultures from the cut surface showed the influenza bacillus with the pneumococcus and streptococcus. Liver and spleen were practically normal. Kidneys were much enlarged; the left 2¼ by 1¾ by 1 inch; the right 2½ by 1¾ by 1. They were quite soft. Pale-yellowish color, the cut surface oily and yellowish-white casts. Relation of the cortex to the medulla is about the same. No cortical markings, medulla is pale with irregular areas of congestion. Microscopic examination of the kidneys showed the glomerular tufts swollen, nuclei more numerous and in some capillary tufts were separated from capsule by a finely granular material. The epithelium, lining the convoluted tubules, was swollen, coarsely granular and the nuclei in many cells not staining with hematoxylin. Some desquamation of renal epithelium. Sprinkled to the cortex are many small areas where the intertubular connective tissue is thickly beset with a mass of round cells forming a minute, yet veritable abscess. Stain for bacteria negative. Section through the consolidated area of lung showed alveoli filled with a cellular mass made up in great part of round cells, with a few fatty epithelial cells and granular debris. There was no fibrin and only rarely any red blood cells in the alveoli. The alveolar connective tissue was densely infiltrated with round cells. In some fields, the alveolar septa cannot be differentiated from the alveolar contents, the whole field consisting of a mass of round cells with some larger epithelial cells, resembling a purulent focus. Some of the pulmonary blood vessels are filled with an organized clot that has become adherent to the vessel wall. The smaller bronchi are filled with masses similar to those in the alveoli (Fig. 1).

Case 4.—Mathew, aged 10 months, weighs 18 pounds; family history unknown; brought up on sterilized milk. Evidences of congenital syphilis were observed when two months of age; papulo-erythematous rash over chest, abdomen and plantar aspect of feet; when six months old had a gumma an inch in diameter on the scalp, over the center of the left parietal bone, and a smaller gumma on the right tibia, both of which quickly resolved under specific treatment. At 8 months had a severe attack of bronchitis lasting two and a half weeks. Good recovery.

Jan. 14, 1901: Refused the greater part of his food and vomited; bowel movements, sour odor and contained considerable mucus, with particles of undigested and greenish material. Severe distention of abdomen. Examination: Moderate nourishment; skin burning hot, dry, no exanthema; tongue slightly coated, two lower incisors; pharynx injected; no pulmonary signs or symptoms, save that the respirations were 40; abdomen distended and tympanitic. Put on appropriate treatment and noted apparently gradual improvement until January 21, when temperature became high, respirations more rapid, and irregular with a soft, small and frequent pulse. Examination: Left lung posteriorly from the left scapula to the base and extending from the spine to the mid-axilla, dulness; bronchial breathing; bronchophony, and consonating râles. Over remainder of chest, lungs are hyper-resonant with many medium-sized râles. Heart rapid, area a trifle reduced—pulmonary distention—abdomen greatly distended; spleen or liver not palpable.

January 25: During the past ten days, child has had little appetite, been very apathetic, content to lie quiet most of the day, but often disturbed by periods of rapid, superficial breathing, attended by great cyanosis. These spells occur at irregular periods from two to five times in twenty-four hours, perhaps more often during the night. Sometimes lasting for an hour and seemed to be relieved by alternating hot and cold baths. Sometimes the child would become very restless, with the abdomen extremely tympanitic, and after the passage of some gases by mouth or rectum, occurring spontaneously or assisted by rectal or gastric tube, would grow quiet again. There has been more or less cough every day; it was dry, short and in paroxysms like a mild pertussis. Sputum was twice obtained; was of a thick, cream-yellow color, and smear and culture showed presence of Pfeiffer's bacillus. Physical examination same as January 22. Slight muco-purulent discharge from both ears.

January 29: Respirations, short and catchy, resonance over the left lung posteriorly is from semi-tympanitic to nearly normal, but over this area can be heard distinctly bronchial breathing and crepitant râles, with fine mucous râles over both lungs.

January 31: Resonance over left lung posteriorly clearer, but breathing has yet a bronchial character. A few crepitant râles over the base.

February 5: Resonance over the area of left lung described, is semi-tympanitic with crepitant and crackling râles, and broncho-vesicular breathing. Ears are getting better, discharge almost ceased and appearance of the drumheads normal. Abdomen distended. General micropolyadenopathy. Child has lost since sick, over three pounds, but for the past few days seems to be becoming stronger and brighter, with keener appetite, though respirations remained hurried and pulse small and frequent.

February 14: Condition of lung much improved, but crepitant and consonating râles remain over left lung posteriorly.

February 18: Yesterday developed varicella. During the past few days has failed very much, has become much emaciated and exhausted.

February 20: Very thin, extremely weak, pulse fast and feeble, respirations frequent, cyanosis and death.

Postmortem.—Body emaciated, the evidences of varicella remain on skin. The lungs show marginal emphysema with irregular areas of congestion. The left lower lobe is of a dark purplish-red color uniformly solid, consistency of the spleen. Section dark-red, granular, with muco-pus exuding from the small bronchi. The tracheal and bronchial mucous membranes congested. Smear from lung shows influenza organisms predominating. The heart, lungs and kidney were normal and spleen slightly enlarged. The stomach greatly distended and contains 16 fluid ounces. The wall is pale and atrophic. The glands in the mesentery are swollen, many to the size of a filbert and are of a deep-red color (Fig. 2).

DISCUSSION.

Dr. I. A. Abt, Chicago—I think we are deeply indebted to the author for this very excellent résumé on protracted and grip pneumonias. It has been my misfortune to have seen quite a number of cases of protracted pneumonia. In my opinion, not all protracted pneumonias are of the grip variety. We know very well that pneumonias, whether broncho or lobar pneumonias, may be due to a streptococcus or a staphylococcus or to the tubercle bacillus, to the influenza bacillus, or perhaps to other micro-organisms. I have seen protracted pneumonias at times when there was no grip epidemic. I have always experienced difficulty in differentiating a possible tubercular consolidation or a diplococcus or an influenza consolidation, and from an empyema. In the cases reported by Dr. Walls there was bronchial breathing without râles over the base of the lung. These cases continue for weeks with sweats and fluctuating temperature, and we are led to suspect empyema. Every clinician of experience knows that a localized accumulation of pus in the thoracic cavity may give rise to bronchial breathing just as in pneumonia. An experience which I have had in more than one case shows the difficulties which may be encountered. Two winters ago, during the time when grip was epidemic, such a case of protracted pneumonia occurred. There was dulness and bronchial breathing over the base of the right lung. I introduced a needle into the lower portion of the thorax and obtained a turbid serum. A culture from this serum showed the presence of diplococci. On the following day another aspiration was made, but no fluid was obtained, probably because all of the fluid present had been evacuated at the first attempt. There was a lobar pneumonia which ran a chronic course for months.

Dr. B. R. Shurly, Detroit—I wish to call attention to observations made on some 16 cases presented; there seemed to be a pseudo-crisis on the *fifth* day.

Dr. Campbell, of Kansas—I would like to ask if the author has had any experience with oxygen gas.

Dr. Walls, in reply—The question of differential diagnosis has been brought up by Dr. Abt. I omitted this part in reading the paper because of the extent of the subject. The differential diagnosis between a consolidation and a collection of fluid at times is certainly hard to make. In one of the cases reported, thoracentesis was performed. Even though in that case the common signs of accumulation of fluid—dulness, dislocation of the heart, and diminution of Traube's space—were not present, it was thought that possibly there was a small collection of fluid in between the fissures of the lung. I did not say that there were no râles heard over the areas of bronchial breathing, but that there were no distinctly fine crepitant râles as heard in the early stages of pneumonia. Crepitating and mucous râles were heard over these areas. They might be heard over fluid, the sounds being conducted from the adjoining lung. The ages of the children varied from ten to fourteen months. I have had no experience with oxygen gas in these cases.

The Paris Students' Co-Operative Restaurant.—Shares to the number of 862 have already been disposed of, so the success of this undertaking is assured. No alcohol will be allowed on the premises, but the fare is to be of the best, at prices constantly lowered by the application of the profits. Professors Gide and Lavisse have been the moving spirits, both men with extensive experience in co-operative enterprises. The doors will open October 15.

MEMBRANOUS COLITIS.*

CHARLES DOUGLAS, M.D.
DETROIT, MICH.

Membranous colitis occurs most frequently in infants over six months old and less than two years, and may appear in those previously in good health. It is usually a very severe irritation, greatly endangering the health and life of the child. While it may follow a catarrhal disturbance, it commonly appears suddenly accompanied by vomiting, high fever, loss of appetite, severe pain and frequent large green stools of a mucous character. The vomiting usually disappears early and the temperature falls within safe limits. Should this not occur the prostration is very great and the child melts away so rapidly that its life is quickly endangered. Usually the abdomen is tender and somewhat swollen. The pain is severe and frequent, especially for a time before stool. Where the irritation is low in the colon, there is marked and severe tenesmus at stool causing an inch or two of the mucous membrane of the bowel to protrude. This is intensely congested and often shows patches of pseudo-membrane on its surface, which fact establishes the diagnosis.

The stools resemble those in catarrhal enteritis, except in the amount of blood, which is generally greater and more constantly present; but the only feature which establishes the diagnosis is the appearance of the pseudo-membrane. This shows as grayish-yellow opaque masses after the stool is washed away. It is then easily distinguished from the accompanying mucus, which is commonly large in quantity. The pseudo-membrane seldom appears in large amounts, and usually disappears from the stools, while the mucus and blood may continue for considerable time afterwards. Usually improvement is indicated by the absence of the blood and the lessening of the mucus, with the return of healthy yellow stool mixed with the mucus. Where this does not occur, and the mucus continues for more than a week as the predominating feature in the stool, the emaciation is marked and the case rapidly becomes grave indeed. The severity of the attack and the gravity of the prognosis are in proportion to the amount of mucus passed daily and the length of time it continues to come. These cases generally recover in ten days or two weeks; where they continue longer the prospect of recovery is not good.

This disease is very rare in young infants under six months of age and is mostly confined to those that are hand-fed, and also improperly fed. Rarely do we find a case appear in a nursing infant, particularly during the first months of its life. In hand-fed infants also, where intelligence demands yellow stools, and industry secures their continuance, it is indeed a very rare thing to see cases of "membranous colitis."

It has been the fortune of the writer to meet with three cases of this disease this year in very young infants. One was in a nursing infant ten days old; one in a hand-fed infant eighteen days old; and the last in an infant partly nursed and partly hand-fed, nine weeks old.

The first or nursed one was an infant, strong and well nourished, weighing nearly nine pounds when born. The mother was a large, active, rosy-colored woman, but one who suffered greatly from acidity and consequent heartburn during her pregnancy. So great was this that she was compelled to live almost entirely during the last two months of her pregnancy on meat, milk and eggs. She had a feeble labor, necessitating forceps delivery, with laceration of the perineum, which was repaired; she made an uneventful recovery, save that she persisted in having a temperature of 102 for several days, and also about 100 for a month or more after her labor. This was accompanied by a coated tongue. The mother was very carefully dieted from the day of labor, and her milk came on the fourth day. The child's bowels were green continually from birth and no food except a little sugar water and a small dilution of cream was fed until the mother nursed it. The stools continued green and slimy, showing only small traces of yellow, till the ninth day, when the child became violently disturbed with high fever, great pain, frequent green mucous stools, straining and tenesmus. It lost flesh rapidly and in the third day of its sickness passed some patches of opaque yellowish membrane looking much like those cast from the throat in diphtheria. The infant was removed from the breast entirely and fed with a cream mixture, on which it convalesced rapidly; the stools became yellow and well formed and all mucus disappeared in ten days. A microscopic examination of this membrane, made by Dr. Perkins, showed the membrane was structureless, like a mass of fibrin with no mucus or epithelial cells.

Culture from this pseudo-membrane showed a bacillus belonging to the colon group, but not the true colon bacillus described in text-books, as it did not coagulate milk, nor give the indol test. The structureless character of this pseudo-membrane showed it to be an exudate due to intoxication from the toxins of these bacilli. Injections of these toxins and the germs into guinea-pigs' abdomens showed an exudate formed over the intestines and the liver, having the same structureless character as the sample.

The second infant was eighteen days old when the writer was called in attendance. This was the fourth child of a mother unable to nurse her children. It had been fed at first on diluted cow's milk, then on diluted cream, next on almost raw oatmeal water and cream, with the result of loss of flesh, constant colic, constipation and stools, when voided, of yellow hard balls, coated with slime and having very foul odors. The symptoms and the recurring colic pointed to a sore spot in the bowel somewhere in the colon, as the pain always returned with great violence about fifteen minutes before stool. Six days after my first visit the stool contained a mass of tough yellowish-white membrane, also looking like that seen in the throat in diphtheria. With a careful adjustment of a cream mixture and the voiding of this membrane, this infant made a rapid recovery, having healthy stools.

A microscopic examination, also by Dr. Perkins, showed this membrane contained fibers of oatmeal husks, pus cells, and small masses of mucous tissue, and imbedded in the tissue were the bacilli of the streptococcus. Cultures made from this membrane showed the proteus vulgaris and streptococcus. Injections of this culture in very small quantities killed guinea-pigs and rabbits, and on the intestines and liver a similar membrane was developed. Experiments show that the growth of the streptococcus in the presence of this very fatal proteus vulgaris, increases the toxic property of the former.

Feeding the nearly raw oatmeal fibers to this infant caused abrasion of the mucous membrane, thus forming a favorable nidus for the entrance of these germs and the consequent formation of this membrane. This child now continues healthy and grows rapidly.

---

* Read at the Fifty-second Annual Meeting of the American Medical Association, in the Section on Diseases of Children, and approved for publication by the Executive Committee of the Section: H. E. Tuley, Edwin Rosenthal and Samuel W. Kelley.

The third child, 9 weeks old, had been nursed by its mother, a delicate neurotic, suffering from middle ear disease. She had rose asthma disturbance every year so that she was compelled to leave her home in May and spend her summers in Lake Superior ports. She nursed her baby for a few weeks and it grew to ten pounds in weight. Sickness compelled her to wean it at five weeks old. Improper adjustment of food to the child's digestive power soon set up a disturbance, causing vomiting and colic with great fermentive accumulations of gas in the stomach and bowels. Changes in the food failed to reach the correct digestive results and the little one continued in distress, losing sleep and weight, till at 9 weeks old, when the writer first saw the infant, it weighed only eight pounds. Examination showed it much emaciated with a distended abdomen and the skin hanging loosely on its body and limbs. Vomiting followed every meal and constipation was the rule, with great pain before stools. The stools were yellow, dry, and covered with thick mucus. The pain at stool and the mucus over the discharges showed a sore spot low in the colon as in the second child. This infant had been fed too much at each meal and also had too much proteid in its food, thus causing indigestion, constipation and irritation of the colon. The nurse said it had passed some patches of membrane before my attendance, but I failed to find any. A careful adjustment of the food failed to make it grow and a wet nurse was necessary to save its life. With the latter it succeeded satisfactorily. The history of this case was so similar to that of No. 2, that the writer regrets his inability to secure a portion of the membrane for pathologic investigation.

While these cases do not conform to the usual symptoms seen in cases of membranous colitis, the writer feels that they belong to it, even though the pathologic evidences differ from each other. The very early age at which this irritation began and the varying character of the stools, make these cases interesting and is the writer's reason for presenting this subject. While only the first case showed the usual symptoms of loose bowels, recognized as accompanying "membranous colitis," the presence of membrane and mucus with pain at the stool even when with a constipated condition, establishes the fact that the irritation and distress are in the colon, and are of a membranous character. While the etiology is similar in these three cases, they show that the bacteriologic factors may differ greatly.

While the cultures from these two samples of membrane do not agree in character, one showing a colon bacillus and the other showing a mixed infection, the proteus vulgaris with the streptococcus, the irritation, pain and distress were similar, and the infants showed the same emaciation, fermentive disturbance and pain prior to stool.

The importance of recognizing the food as the cause of the sickness in both nursed and hand-fed infants, can not be overestimated. The difference in the character of the food will no doubt account for the different germs in these two cases, the nursed infant showing only a colon bacillus, while the hand-fed one showed two foreign ones.

Writers on this disease describe the loose slimy or mucous character of the stools and their great frequency; but here were two cases, Nos. 2 and 3, which showed a constipated stool of yellow color and yet membrane was present in both.

These cases illustrate the absolute necessity there is always for the physician to examine the stools himself in gastro-enteric disturbances. Few parents or nurses are skilful and watchful enough to read carefully the digestive process as it is illustrated in this stool product. Only the experienced eye, nose and finger of the physician is capable of doing this work correctly. Only by the knowledge obtained in this way can a correct conception of the digestive errors be obtained, and consequently the right changes be made to meet this difficulty in each and every case of gastro-intestinal disturbance. Without such personal examination by the physician, his ideas of the situation are necessarily second-hand ones and the treatment liable to be wrong.

These cases also show that different bacilli have the power, by their irritative qualities, to form a false membrane on the mucous membrane of the bowels.

URETERAL CALCULUS ACCURATELY LOCATED BY THE X-RAYS AND REMOVED BY AN EXTRAPERITONEAL OPERATION.*

W. W. KEEN, M.D., LL.D., F.R.C.S. (Hon.)
Professor of the Principles of Surgery and of Clinical Surgery, Jefferson Medical College.
PHILADELPHIA.

Henry E. S., aged 10, of New Bloomfield, Pa., was admitted to the Jefferson Medical College Hospital Oct. 25, 1900, at the request of Dr. E. E. Moore.

Neither his family nor personal history, other than as related below, have any bearing on the case. When he was 2 years old he had an attack of pain in which he passed bloody urine. Five years ago—at the age of 5—he had another attack of severe pain in the region of the left kidney. The pain extended downward into the scrotum and to the head of the penis. It was finally relieved by the application of heat and the use of morphin. Similar attacks have recurred at varying intervals, sometimes every three or four days, sometimes not for two months. During the winter of 1897-98, in several attacks he passed bloody urine and uric acid crystals. What he thinks was a small stone escaped in September, 1900, but neither he nor any one else examined it carefully. In February, 1900, he had scarlet fever and since then his attacks have been much more frequent and severe. He has never had any pain on the right side.

On admission the entire left side of the abdomen was so painful that it was impossible to make any diagnosis as to the location of a stone, though the diagnosis of calculus was perfectly clear and had already been made by his physician. The urine which he passed on admission was clear, amber-colored, sp. gr. 1013, reaction acid, no albumin, sugar, blood, pus or casts present, urea 1.1 per cent.

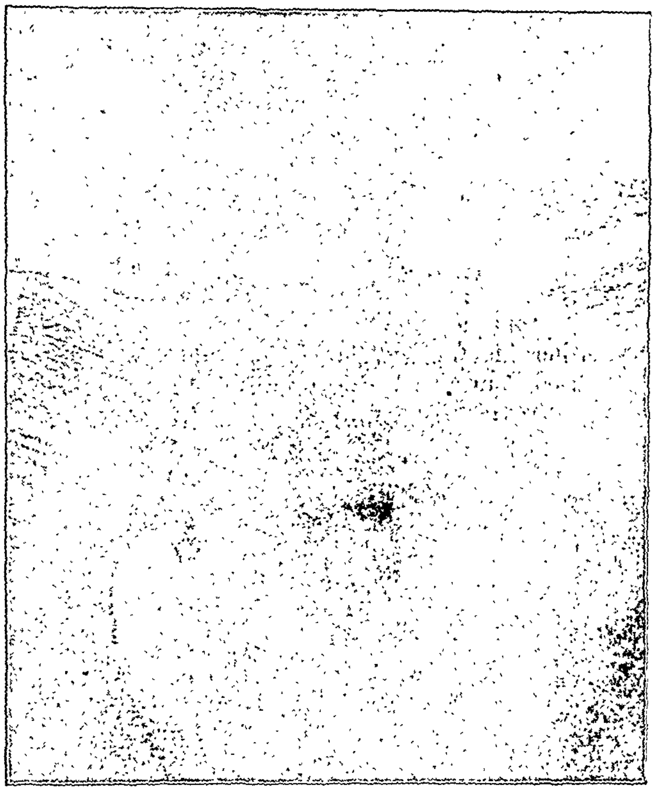
Dr. Charles L. Leonard took a skiagraph (see Fig.) which showed a ureteral calculus about one-half the size of the last joint of the little finger, in the left ureter, which was thought to be at the pelvic brim, but at the operation was found a little below this level somewhat nearer the bladder.

At the operation, Oct. 31, 1900, I made an oblique incision from above the crest of the ilium and parallel to it, extending to a point above the middle of Poupart's ligament, and pushed back the peritoneum. I had considerable difficulty in finding the ureter. It was raised with the peritoneum, but was so small, flattened and indistinct that it was some time before I could recognize it. Tracing it downward, just below the pelvic brim, I found a hard mass in which the ureter was apparently lost. No stone could be felt at first, but on cautiously cutting and tearing through the mass, I discovered a ureteral calculus measuring 1.5 cm. in length, 1 cm. in breadth and 8 mm. in thickness. The exterior was rough from the points of many spicules due to crystals, which by their fusion constituted the solid mass. The sharp spicula were especially marked at the two ends. Professor Coplin examined it and reported that the stone was quite dense; the nucleus was dark in color and gave the reaction for mucin. The shell was of calcium phosphate with a trace of organic matter.

---

* Read at the Fifty-second Annual Meeting of the American Medical Association, in the Section on Diseases of Children, and approved for publication by the Executive Committee of the Section: H. E. Tuley, Edwin Rosenthal and Samuel W. Kelley.

Evidently the calculus had ulcerated its way through the posterior wall of the ureter, had matted together the rectum and ureter and lay in a pouch which was partly intra-ureteral and partly extra-ureteral. The caliber of the ureter was not entirely blocked up by the calculus. The moment that I opened the ureter a very considerable amount of urine, which I estimated at about one-quarter of an ounce, escaped through the ureter from the somewhat hydronephrotic kidney. Though the kidney was somewhat distended, I judged that on removal of the obstruction it would recover itself, especially in view of the recuperative powers of childhood. The edges of the opening in the ureter were then closed by a continuous catgut suture. In view, however, of the inflammatory conditions present, as there would almost certainly be some leakage of urine, I packed a small amount of iodoform gauze against the sutured opening and led the end out through the wound. The muscular wall of the abdomen was then closed with a continuous silk suture, and the skin with interrupted silkworm gut sutures. The gauze packing was removed on the second day after the operation, as I found no leakage took place. He made a perfectly smooth recovery, the highest temperature having only once been 100 degrees. He was kept in bed for between three and four weeks, so as to allow firm union to occur, with a view to preventing a hernia.



March 22, 1901, a letter from Dr. Moore stated that when he reached home, November 28, he was suffering considerably from pain in the region of the left kidney. Examination of the urine showed the phosphates to be greatly in excess. A purge of calomel relieved him from pain and he has never had any since. There is also no sign of hernia at the site of the wound.

No remarks are needed save to call attention to the accuracy and value of the *x*-ray picture, both as an absolute verification of the diagnosis and as a guide at the time of operation. Instead of having to open the kidney with the idea that the stone might be there, or to examine the entire length of the ureter to find it, the skiagraph guided me at once to the exact location of the stone.

DISCUSSION.

Dr. Edwin Rosenthal, Philadelphia—I have at home a small calculus that was passed by a Russian boy *per urethram*. The stone had caused considerable pain and hemorrhage. Microscopic examination showed no diseased condition of the urethra, bladder, ureter or kidneys. The case was seen before the discovery of the *x*-rays and treatment was purely expectant.

I have in mind two cases ending fatally, which I watched carefully almost from their inception. The first diagnosis was calculus. This was followed by hydronephrosis, and still later by pyonephrosis. There was a large tumor on the affected side, which was aspirated once or twice before death. The postmortem revealed the presence of the calculus. If we had only known it I am certain that the life of both these persons could have been saved. Dr. Willy Meyer had examined these cases, and had stated that the pus was from the right side.

Dr. C. L. Leonard, Philadelphia—I have examined and found 47 cases of calculus in the kidney and ureter. In over 50 per cent. of the cases the stone was in the ureter. Of this number, in 4 cases, the expectant line of treatment has been followed, and the patients have passed the calculi. The exact localization of the calculi makes it rational in the case of minute calculi, to adopt this line of treatment. If the symptoms become more severe, the skiagraph enables us to locate and remove the calculus. Where the latter is lodged in the lower part of the ureter, and there has been much inflammation, it is very difficult in the male to reach the stone. In the female it is somewhat more easy. I have had four other cases in which small calculi have been passed while the patient has been waiting for operation. In cases like the case reported, the size of the stone makes it evident that operation is the only course of treatment. The skiagraph, however, localizes the area of operative intervention, simplifies it, and makes it complete.

Dr. S. W. Kelley, Cleveland—I feel gratified that Dr. Keen has reported this case. In my address on the first day, I emphasized the importance of surgery in children, and commented upon the general neglect of this department of pediatrics. A report of this kind is most appropriate for presentation to this Section, and we hope to have more of them.

Dr. Clifton Scott, Des Moines—I am very sure that the value of the *x*-ray method here is of negative as well as of positive value. I had under observation an adult whose illness I diagnosed at first as nephritic colic. If an *x*-ray examination had failed to show the presence of a renal or a ureteral calculus, my error would have been shown. As the hemorrhage continued, and small clots were discharged, the case passed into other hands. An operation was undertaken in the region of the kidney. A tumor of endothelial origin was revealed which had invaded the pelvis of the kidney, and had given rise to the hemorrhage. There was no calculus present.

DR. W. W. KEEN, in reply—I have on at least four occasions cut down upon the kidney in adults under the impression that I had to deal with a stone, and in each instance no stone was found. I think that with the use of the *x*-rays the negative value is quite as great as its positive value by enabling us to avoid such mistakes in operation.

REMARKS ON SPINAL SURGERY, WITH ILLUSTRATIVE CASES.*

ANDREW J. McCOSH, M.D.
NEW YORK CITY.

The spinal canal has for many centuries been considered legitimate ground for operative procedures. As early as the 7th century the advisability of operation for fractured spine was urged by Paul d'Egine[1] and others. In the 16th century and since that time, various surgeons have advised operative interference for the relief of this condition, but it was probably not until the beginning of the 19th century that a definite operation was performed for a fractured spine. Since then the subject has constantly thrust itself into prominence and has been much debated and often with considerable heat and vigor. This was especially true of a discussion which took place in the Royal Society of Surgery of London in 1820.

About the same time (1823), A. Cooper wrote: "If you could save one life in ten, aye, one in a hundred, by such an operation, it is your duty to attempt it, notwithstanding any objections which some foolish persons may have urged against it. Though I may not live long enough to see the operation frequently performed, I have no doubt that it will be occasionally performed with success. There is no reason why it should not, and he who says it should not be attempted, is a blockhead." This opinion of the great English surgeon will be accepted by most of us, and it is not very flattering for our self-conceit to feel that at the present day we can not honestly offer a much more favorable prognosis than was given in this statement written nearly a century ago.

Even at the present day there is some difference of opinion on this subject. I remember only last year in an editorial in one of our own leading journals operation on this class of cases was almost condemned or at least no encouragement was given for operative interference. It is true that the majority of cases of severe injury to the spinal column must perish but undoubtedly many a life has been saved by timely interference. I say "timely," for unfortunately delay of a few days before the operation has been performed has in more than one case been responsible for its failure. The tendency in the past has been much more toward the "waiting and watching policy" than has been the case when the brain is compressed by bony fragments. There are quite as urgent reasons for rapid relief in cases of pressure on the cord as there are in cases of depressed fractures of the skull, though perhaps it must be said the results of operation for the relief of fractured vertebræ are less satisfactory than are those for fractured skull, at least such has been the case in the past. The reverse may be said to be true in regard to tumors. Early operation in cases of injury of the vertebræ is of the utmost importance. Of course at times there may be good reasons for delay. The patient may be in a condition of great shock due very possibly to severe injuries of other organs. In such an event it is wiser to wait until it at least can be determined that the case is not one which under any circumstances must end fatally. If it be such, no benefit can be derived from operation. Again, it is sometimes difficult to determine that the symptoms are not due to mere contusion of the cord, or to more pronounced hemorrhage within the substance of the cord—hematomyelia. A certain time must often elapse before this point can be determined.

In this class of cases where surgical interference is not indicated, the symptoms are apt to be of an irregular type. The muscular paralyses are not complete and often the muscles of the same group may not be equally affected; the anesthesia is only partial and paresthesia with patches of hyperesthesia is common. The symptoms of irritation are apt to be less pronounced, though there may be mild twitching at first of certain muscles. The reflexes are not apt to be abolished, though they may be altered. The following cases are in many respects typical:

CASE 1.—Concussion upper Dorsal Cord: Slight Disturbances, sensation and motion; Recovery: D. O. C., male, aged 20. On April 5, 1891, when intoxicated, fell two stories, lighting on his back. He was helpless when found. He complained of pain in the back of the neck. There was no deformity. On April 6, there was evidence of some weakness of the left arm, especially in the flexor muscles. Both patellar reflexes were very feeble. Several areas of paresthesia were present in the lower extremities and trunk. On April 7 and 8, the weakness of the right arm manifested itself. There was more or less persistent priapism. On April 12, the symptoms began to improve and continued so until he was discharged on May 25, when with the exception of slight weakness of the left arm he was practically well.

CASE 2.—Injury of Lumbar Cord; Probably due to hemorrhage; Disturbances of Motion and Sensation; Pain; Ultimate Recovery without Operation: J. O. B., male, aged 34, on July 23, 1889, fell down the shaft of an elevator a distance of 30 feet. He lighted on his feet but fell down and was unable to rise. He had lost almost all power over his lower extremities. He was taken to a hospital in an ambulance. He suffered from considerable neuralgic pains in his legs and feet, and his legs and thighs felt numb and were partially paralyzed.

He was brought to the Presbyterian Hospital on July 27 with a diagnosis of fracture of the second and third lumbar vertebræ. On examination it was found that the peroneal and anterior tibial groups of muscles were partially paralyzed, especially on the left side. There was an anesthetic band extending from the outer side of the foot upwards along the outer and posterior side of legs as far as the middle of the thighs. A few days later it was found that a. c. c. was greater than c. c. c.

It was considered wise to defer the operation as there seemed to be some improvement in the paralyzed muscles. The pain was disappearing, there were no spasmodic movements of the muscles and no contracture developed. Through August and September gradual though slow improvement both as regards motion and sensation took place. He was discharged from the hospital on October 1, at which time he could walk about the ward though he still suffered from foot-drop. After his discharge he continued slowly to improve and at the end of a year he was practically well.

CASE 3.—Concussion of Lower Dorsal Cord; Slight Disturbances of Sensation and Motion; Recovery without Operation: J. D., male, aged 25, on June 1, 1901, while in the act of boarding a car, was struck on the back by a car coming in the opposite direction. He was knocked down and when found by the ambulance surgeon was in a state of considerable shock. He was slightly alcoholic, and complained of extreme pain in the lower dorsal region.

---

* Read at the Fifty-second Annual Meeting of the American Medical Association, in the Section on Surgery and Anatomy, and approved for publication by the Executive Committee of the Section: W. J. Mayo, H. O. Walker, and A. J. Ochsner.

[1] Trans. by René Briau, p. 409.

On admission his temp. was 99 1/3, pulse 102. There was a large effusion of blood in the lower dorsal region and apparently some deformity of the tenth, eleventh, and twelfth dorsal spines. He complained of shooting pains in the lower extremities and there was some loss of power in the muscles on the outer side of the legs and feet. There was some paraparesis in irregular patches on the back of his thighs and buttocks. The patella reflexes were diminished. There was no complete anesthesia.

The diagnosis was made of hematomyelia in the lower dorsal and upper lumbar cord. On the day following his admission to the hospital his symptoms began to improve. At the end of two weeks the muscular paresis had almost disappeared, though there were still some irregular areas of diminished sensation. The patella reflexes at this time were somewhat exaggerated. On August 1 he was able with support to move about the ward, and when he was discharged on August 8 his paralyses had practically disappeared. By November 1 he was able to resume work, having entirely recovered except for some slight stiffness and an occasional pain in the back.

Case 4.—Concussion of lower Dorsal Cord; Disturbances of Sensation and Motion; Recovery: H. L., male, aged 44, on March 20, 1895, fell backward over a pile of stones. In ten minutes there was complete loss of power in both lower extremities. This persisted for a few hours. There was also complete anesthesia below a line drawn through the umbilicus. For the first few hours the patella reflexes were lost. At the end of 24 hours slight improvement in the motor paralysis began. But little change occurred in the area of anesthesia, until after a week had elapsed. At this time also the reflexes began to reappear. At the end of three weeks he had gained almost complete control of his lower extremities and the anesthesia was rapidly disappearing. At the end of six weeks all symptoms had practically disappeared.

On the other hand where there is definite pressure of bone on some portion of the cord the parts supplied from this center are apt to be more distinctly and more decidedly affected. The paralyses are generally complete and more regular as to grouping; the anesthesia also is apt to be complete with or without a band of hyperesthesia. The reflexes are apt to be abolished. Generally within a few hours a differential diagnosis between these two conditions can be made, but if at the end of 12 or 24 hours there still be question as to the cause of the paralyses it seems to me wiser to at least do an exploratory operation. The danger of this is slight. If a fracture be found there can be no question as to the propriety of the operation. If none be found but little harm has been done to the patient. In similar cases of injuries to the head it is almost routine procedure to cut down upon the skull in order to ascertain if a fracture be present. In the spine the operation is, of course, somewhat more severe, but not sufficiently so to contra-indicate its performance in cases of doubt.

The differences between these two classes of cases are sometimes, however, less marked, and as already said in certain cases in the first 12 or 24 hours it is sometimes exceedingly difficult to determine whether or not the lesion is one which can be relieved by operation. Where the symptoms are severe there can be but little question between concussion on the one hand and compression or crush on the other, but it is in the milder cases where the surgeon must sometimes be in doubt; and here a delay of 12, 24 or even 48 hours can do but little harm, and if the diagnosis be uncertain it is wiser to delay. In the severer cases, there can seldom be question between mere concussion and compression by bony fragments. The question, however, will be whether the cord be completely crushed or whether it be merely contused and pressed upon by broken bone. In many cases it is impossible within the first few hours to determine which of these conditions is present. A day or two's delay will probably settle this point. But it is exactly such delay which makes the recovery hopeless.

As yet, we have not sufficient experience or knowledge to make any definite statement concerning the early symptoms which indicate complete destruction of the cord. We do know, however, that if certain symptoms be allowed to persist for days or weeks that the case will be hopeless. It is our duty to make an attempt to relieve these symptoms and their cause before it is too late. It has been stated more than once that where there is complete loss of sensation, motion and patellar reflexes in both lower extremities that the symptoms indicate a complete crush of the cord and that the case is absolutely hopeless. This view, however, is not correct, as has been shown by more than one case where all these symptoms have been present, and yet where after removal of fragments of bone recovery has resulted. The following case is to be added to this list. In this case both deep and superficial reflexes were lost. Had operation been delayed, however, they might have returned.

Case 5.—Fracture of seventh Dorsal Vertebra; Pressure on Cord producing loss of Sensation and Motion and patellar reflexes; Operation; Recovery: J. L., male, aged 27, was thrown from a railroad train on July 3, 1891, striking on his back. For a few minutes consciousness was lost. When brought to the hospital three hours later, there was found to be complete muscular paralysis of both lower extremities, retention of urine and loss of power over rectum. He was in condition of slight shock; temperature 100, pulse 110. There was complete loss of sensation below a line just beneath the tip of the ensiform cartilage. Tendon reflexes in both knees, as also the cremasteric and abdominal, were completely lost. At the end of 8 hours after the accident his temperature had risen to 103.5; loss of motion and sensation, and patella reflexes remained as before. On examination of his back there was found to be a depression below the seventh dorsal spine, at which point there was marked local tenderness.

The diagnosis of fracture of the seventh dorsal vertebra was made and operation advised. One hour later, that is to say, nine hours after the injury, ether was administered. An incision was made from the fifth to the eighth dorsal spines. The spinous process and the laminæ of the seventh dorsal vertebra were found shattered into several fragments. A line of fracture extended forwards on the right side into the transverse process. Four or five bony fragments were removed. The dura was lacerated and the cord was contused, markedly congested and studded here and there with small hemorrhages. A probe passed upwards and downwards met with no further obstruction. The wound was left partially open, as was also the dura.

The shock of the operation was very slight, the patient making an excellent recovery. For five days no special change in symptoms was noted. He then began to feel some tingling and pricking on the outer side of his thighs and legs. On the 14th day he was able to slightly move his toes and at this time sensation began to return in his lower extremities. Improvement continued; he began to gain control over his bladder and rectum. On the 30th day he could draw his legs up and down in bed, flexing his knees. His patella reflexes had returned to a slight degree in each knee. On the 60th day he was able to sit up in a chair and sensation was rapidly returning. He left the hospital on the 76th day after his accident and at that time could walk when supported on each side. He came to see me three months later and reported that he was about to resume his work. He still felt some slight weakness in his lower extremities but sensation and his patella reflexes seemed normal. Some five years later he met me on the street and reported that he had been perfectly well ever since, that his back was as strong and as limber as ever.

There is a certain class of cases where following injury of the cord, and immediate development of severe symptoms, improvement has set in at an early period and has been up to a certain point and for a certain time progressive. Then, after the expiration of weeks, perhaps of months, it ceases, degenerate changes begin, and if unrelieved in a year or two, bedsores, cystitis or some other complication will end the patient's very miserable existence. In such patients the symptoms may be due to lesions of different character, to blood and inflammatory extravasations as well as to pressure by fragments of bone. The former disappear gradually as time advances, the latter can only be removed by operation. It is difficult to determine which one of these causes is responsible for the symptoms but as long as improvement continues it is wiser to wait unless there be proof positive that a fragment of bone presses on the cord; but as soon as it can be ascertained that progress has ceased and degenerative changes have begun then operation should at once be resorted to. It may not be a success, for the degeneration already begun in certain tracts may be beyond recovery, but at least it should be attempted as it can do no harm and all hope of recovery is otherwise rejected.

It should always be borne in mind that spinal centers will, in spite of severe injury or long continued irritation, still preserve their vitality and that after the removal of the irritation or destroying cause they have remarkable recuperating power which enables them to rapidly gain control over their lost functions. A case where such an operation was remarkably successful is as follows:

Case 6.—Old Fracture Fourth Cervical Vertebra; Extensive Paralysis resulting; Laminectomy eight months later; Cure: E. G., aged 33, a sailor, in October, 1889, during a storm at sea, was struck in the right side of the head by an iron tackle fastened to the end of a loose sail. He was thrown violently to the deck, striking against the anchor. When found he was doubled up, arms and thighs rigidly flexed; head inclined forward, resting on his chest. For a time he was unconscious; on recovering consciousness in an hour or so there was found to be paralysis of the trunk and extremity below the clavicles. It was complete except in the right leg, where it was partial. The head remained flexed on the chest, the patient not being able to hold it erect or move it laterally. For a day or two following the accident he was delirious and restless. For two weeks deglutition was difficult. There was retention of urine for several days; incontinence for one month. For some days there was priapism. Obstinate constipation persisted for some weeks. At first he complained of severe pain in the back of the neck, at first sharp, later dull and aching. Sensation was moderately disturbed. In addition to areas of anesthesia there was for some weeks sensations of pricking and formication.

The rigidity of the arms and legs with more or less muscular paralysis persisted until December. During this time contractures of various muscles developed, as well as wasting of groups of muscles. The paralysis of the right leg slowly improved. After Christmas the right arm began to improve slowly and soon after some return of power in the left arm was noticed. During January he was able to move slightly his arms and legs, and at the end of the month could stand when well supported but could not walk. The improvement, however, did not continue and during February there was some deterioration in muscular power. Since that time there had been no progress in spite of the use of electricity and massage. Marked rigidity of the muscles with contractures of the left upper extremity developed. Some slight motion of the head from right to left returned but he was unable to either raise it from his chest or to hold it erect. Any motion of his extremities or head produced pain on the left side of the neck near the fifth spine where tenderness was the greatest.

He was admitted to the Presbyterian Hospital, May 26, 1890. He was a fairly nourished man with normal temperature. On examination it was found that there was marked loss of power in the left forearm and hand and practically complete paralysis of the arm and shoulder. There was considerable paralysis of both lower extremities to such an extent that it was impossible for him to stand upright without a support on each side. There was also considerable rigidity of the muscles of the left upper extremity. There was considerable atrophy of all the muscles of both extremities, being especially marked in the left arm and trapezius. There was decided paralysis of the muscles of the back of the neck, so much so that the head rested forward with the chin on the chest. He could not raise it and lateral motion was very limited. The areas of anesthesia were somewhat irregular. Sensation below the third rib was very considerably diminished, being most marked in the lower and upper extremities and in the left side of the trunk. The patella reflex of the left leg was markedly exaggerated, and the right slightly increased. There was slight clonus on each side. There were evidences of vasomotor disturbances, the skin being moist and glossy. When in bed resting quietly the patient was free from pain, but movement caused considerable pain, especially in the back of the neck and left shoulder. The patient wore a jury-mast to support his head. Tenderness was elicited by pressure on the back of the neck between the fourth and fifth cervical spines where, on rotation of the head, there was an indistinct crepitus. It was decided that the cord was compressed by either bone or inflammatory exudate in the neighborhood of the fourth or fifth cervical vertebra.

Operation June 4; ether. An incision was made along the spines from the base of the skull to the sixth or seventh cervical spine. When the spines were disclosed it was seen that there was some displacement of the fourth with its lamina. The spine and lamina of the fourth and fifth cervical vertebra were removed. The fourth lamina had evidently been fractured and exerted, posteriorly, considerable pressure on the cord. Under it was found a new layer of connective tissue with a much thickened dura, the combined thickness of which was about a quarter of an inch. No adipose tissue was present and the thickening extended from the middle of the third to the lower border of the fifth vertebra. It was evidently due to a hemorrhage which had become organized. The dura was found adherent to the cord, it was opened and the cord was seen to be more or less congested, the layer of connective tissue was removed and the dura loosely sutured. The wound was irrigated and partially closed by suture. Moderate shock and considerable pain followed. Elevation of temperature was very slight, and the wound healing was uneventful. On June 10, the patient noticed some improvement of the right hand, as he was able to clinch his fingers tightly and more motion could be made at the elbow. On June 26, improvement was very noticeable; even with his left hand he could pick up a handkerchief from the bed. Improvement of all the muscles was rapid and progressing so that on July 1 he was able to walk with slight support. On July 10, with the aid of a cane he was able to walk up and down the ward and could raise both arms to the top of his head. His pains have entirely disappeared as had also the muscular contractions. By the dynamometer his grip increased at the rate of three pounds a week. On August 8 he walked a mile and a half and could move arms and head freely. His head when raised could be held erect for a few minutes, but he still wore a jury-mast. On August 10 he went to a dime museum where he exhibited himself. In the following January he was able to cast aside his jury-mast. He could walk many miles a day without fatigue, and had almost perfect use of his hands and arms. In 1898, he in the meantime *having gone back to England*, wrote me a letter stating he was perfectly well.

Other cases of laminectomy performed by me are as follows:

Case 7.—Fracture of Tenth Dorsal Vertebra; Operation; Death in 2 months from Sepsis due to Bed-sores and Cystitis: J. H., male, aged 42, on the afternoon of June 20, 1891, fell from a height of 30 feet, struck on his back and became at once paralyzed below the waist line. On admission to the hospital two hours later, he was *suffering from considerable shock, temperature* 100.5, respiration 36, pulse 120. There was complete muscular paralysis below a line around the umbilicus. There was complete anesthesia below a line drawn around the crests of the ilium and above this a band three inches deep of diminished sensation. His reflexes, both deep and superficial, were abolished. Ankle clonus was present. Respiration was mainly thoracic and somewhat labored. *The eleventh dorsal spine was* prominent and seemed to deviate towards the left. At this point there was marked local tenderness. The bladder and rectum were paralyzed.

The diagnosis was made of fracture of the tenth or eleventh dorsal vertebra with a crush of the cord at this point. Immediate operation was advised but the patient refused to consent until June 27. *During this seven days' delay the patient lost* considerable strength, his temperature was elevated two or three degrees and a cystitis developed. On the 27, ether was administered. An incision was made from the tenth dorsal to the first lumbar spine. A fracture was found of the tenth dorsal spine running along the left lamina of the same vertebra. The lamina of the eleventh was also fractured. Several bony fragments, which had pressed upon the cord and lacerated the dura, were removed. The cord was contused and deeply congested but was not completely crushed. There was considerable inflammatory exudate between the dura and the cord. The wound was irrigated and partially sutured. Some shock followed but three days later the patient's condition seemed somewhat improved. The cystitis, however, continued and a sloughing bed-sore developed over the sacrum. Through the month of July there was gradual increase of the bed-sores, and a nephritis developed. He was free from pain and the wound healed by August 1. Soon after this he began to fail, and on August 22 he died from sepsis due to bed-sores and from uremia.

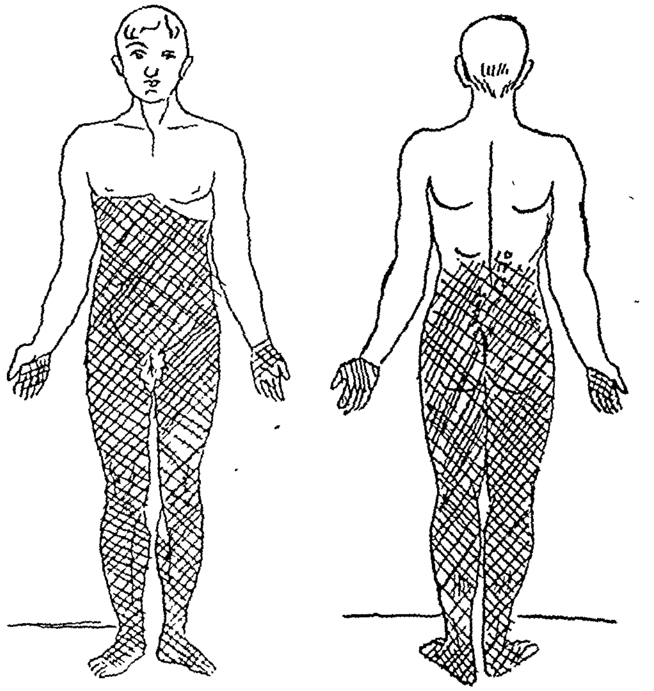
Case 8.—Fracture of Seventh Cervical Vertebra; Operation; Death: T. C., male, aged 41, fell while intoxicated on June 1, 1892, from a height of 8 feet and struck on his head and neck. He was unconscious for a few moments; paralysis of his lower extremities with anesthesia immediately developed. When admitted to the hospital *his general condition was good;* temperature 98, respiration 16, pulse 72. On examination there was complete motor and sensory paralysis from a line in front two inches above the nipples and extending laterally at about the level of the axillary artery. *The patella reflexes were completely lost;* no ankle clonus; no paralysis or anesthesia of the arms; priapism.

Operation six hours later. *An incision with its center over* the seventh cervical spine was made. The spine and arch of the seventh cervical vertebra were found fractured extensively. Several bony fragments were removed. The dura was torn. The cord was contused and congested but seemed intact. The probe passed three inches upward and downward felt no irregularity of bone. The wound was irrigated and partially sutured. *Very little shock followed the operation*, but the temperature gradually rose; the respiration became more embarrassed and he died at 6 a. m. on June 2.

Case 9.—Fracture of Third Cervical Vertebra; Laminectomy; Death: G. A., 65 years, on the afternoon of July 12, 1890, fell three stories, striking on his head and side. Shock was profound and breathing very much embarrassed, the extraordinary muscles of respiration being extensively used. On admission to the hospital at 2:30 p. m., his temperature was 97.5. For some hours there was no distinct evidence of paralysis. At about 6 p. m. it was noticed first in the muscles of the right leg and spread rapidly to the muscles of the entire body and extremities. At 9:30 p. m. the temperature was 103.5; *there was complete anesthesia below a line drawn through the nipples and also a band running down both arms. All reflexes* were entirely abolished. During the night, stupor developed and the temperature *rose to* 106. Operation was made at *1:30 p. m. on July 13. No anesthetic was employed.* An incision was made from the base of the skull to the seventh cervical spine. A comminuted fracture of the second spine and *lamina of the third was found.* Several bony fragments were removed. The right transverse process of the third vertebra was loose but was not disturbed. The dura was not opened. The operation had little effect on the patient. The stupor increased, the temperature rose to 109, the breathing became shallower and he died in twelve hours from respiratory failure.

Case 10.—Fracture of Cervical Vertebra; Laminectomy; *Failure to find seat of crushed Cord because of irregular Distribution of Paralysis:* M. M., female, aged 35, was, on September 27, when in the act of getting into a folding bed, struck by the upper erect portion falling against her back across the shoulders and pinning her down in a *doubled-up position*, where she remained for fifteen minutes before she was extricated. When found she was unable to move her trunk and her upper and lower extremities felt numb and powerless. Shortly afterwards there was complete paralysis of the lower extremities and she was *unable to close her fists. Retention of* urine and obstinate constipation followed. She suffered some pain in the back of her neck and shoulders but it was not severe She felt numbness *in the upper and lower extremities and* trunk. She was unable to move her arms and to flex, extend, and rotate the forearms. The bladder and rectum remained paralyzed.

She was admitted to the hospital three days later. She was a large fleshy woman in a fair general condition; mind clear. She complained of slight pain in the back of neck, of numbness and sensation of pins and needles all over the body. Motor paralysis was complete below the diaphragm. The diaphragm and intercostal muscles acted normally. There was partial paralysis of arms and shoulders, but she could move them slowly both in flexion and extension, which movements, however, were diminished at the elbow and absolutely lost at the wrist. *All reflexes below the waist line were abolished.* The eyes were normal. There was some pain and tenderness at the lower part of the back of the neck, but no irregularity of the



Case 10.

Patient has sensation of touch all over, but in shaded lines on trunk the sensations of pain, heat and cold are absent. Note the difference in hands.

Patient has sensation of touch all over, but in shaded lines on trunk the sensations of pain, heat and cold are absent. Note the difference in hands.

bony outline could be felt either in the throat or in the neck. There was no stiffness of the muscles of the neck.

The diagnosis of fracture dislocation in the neighborhood of the sixth or seventh cervical vertebra was made. The symptoms, both motor and sensory, seemed to point to the location of the injury, probably to a crush of the cord at a point between the sixth cervical and second dorsal vertebra.

As will be seen in the diagram there was an area of anesthesia on the hands but none on the arms.

Consent, however, could not be obtained to operation until October 5, when, with the aid of Schleich's infiltration method, with a few whiffs of chloroform, an incision six and a half inches long was made from the fourth cervical to the first dorsal spines. The spines and laminæ of the sixth and seventh cervical were removed. There were no evidences of hemorrhage or fractured bone. A probe passed four inches downward inside the spinal canal and one and a half inches upward met with no obstruction. The dura looked normal. It was opened but there was no evidence of injury to the cord; where it was exposed for three or four inches the dura was sutured and the external wound closed by suture with the exception of a narrow space for a gauze drain. Time of operation was 45 minutes.

No shock followed, but also no improvement. The temperature which before the operation had ranged between 98.5 and 101 now steadily rose, till on October 11 it reached 106. Extensive bed-sores with rapidly spreading sloughs developed on each buttock. The temperature continued to rise till on the 19th it reached 110, on which day she died.

At autopsy there was found to have been a complete separation between the fourth and fifth cervical vertebra where there evidently had been a dislocation which had immediately sprung back after crushing the cord opposite the interspace between the fourth and fifth cervical vertebra. For half an inch or so the cord at this point was disintegrated and running upward and downward from this point were degenerated nerve tracts. The distribution of nerves in this case was most peculiar. A more careful study of sections of the cord, etc., will be found in "Med. and Surg. Report of Presbyterian Hospital," New York. Vol. V.

In 159 cases collected by Lloyd there were 59 deaths following immediately after operation and 32 at a later period. The so-called operative mortality was 49.18 per cent. Of my own laminectomies in fractures of the spine, 6 in number, 2 have recovered and 4 have died.

(To be continued.)

THE GYNECOLOGIST AS CONSULTANT.*

HUNTER ROBB, M.D.

Professor of Gynecology, Western Reserve University; Gynecologist-in-Chief to the Lakeside Hospital.

CLEVELAND, OHIO.

Since my audience to-day consists mainly of men in general practice, who have to deal with more common, though possibly sometimes fully as difficult, conditions, as those encountered by the specialists, I thought it would be well to touch briefly upon a subject which must interest all of us, and to suggest a few ideas upon which may be based a discussion which may serve to elucidate more freely certain points dealing with the relations of the gynecologist to the general practitioner, and show how one can help the other to their mutual advantage as well as to the best interests of the patient. I shall, therefore, deal briefly with the following questions: 1. What are the qualifications necessary to render a man fit to take up gynecology as a specialty? 2. When should his aid be sought by the general practitioner? 3. How can this aid be sought for and given without detriment to the general practitioner?

In the first place the gynecologist, no less than any other specialist, must have had a thorough, broad training and experience in general medicine and surgery before taking up his specialty. But just here—quoting from a paper written by me some time ago—I would say that the argument so often heard, that gynecology is only a branch of surgery, and that the general surgeon is therefore better equipped to operate upon diseased conditions of the reproductive organs than is the gynecologist, would not seem to be wholly logical. Although only a branch of general surgery, under the circumstances existing at the present day, gynecology presents such a wide and important field that it requires the entire attention of the man who intends to obtain the best possible results. It is true that no one should practice gynecology unless he has a thorough understanding of the principles of general surgery, and every surgeon should also have had a good laboratory training in bacteriology and pathology. As a consequence of such a deficiency in their training we too often find surgeons who have little or no appreciation of surgery except from a mechanical standpoint. Much still remains to be developed in gynecology, from the operative point of view as well as from the pathologic and bacteriologic sides of the question, and it will hardly be disputed that the gynecologist, all other things being equal, is better qualified to scientifically investigate the problems connected with his special branch than those who are able to devote only a part of their time to the subject. It is owing to the investigations of the gynecologist that pelvic surgery has reached the high plane that it holds to-day. To anyone familiar with the development of the various operative procedures that are carried out for pathologic lesions of the pelvis, it is readily apparent that the necessary technique has been evolved by the gynecologist and not by the general surgeon. In order to appreciate the present condition of affairs one has only to compare the results obtained by any well-known general surgeon with those of the gynecologist in the first rank in a similar line of work, both as to morbidity and mortality. Taken as a whole the evidence will be found to be strongly in favor of the gynecologist. That there really exists a wide difference between pelvic operations and those belonging to other parts of the body can be well seen by observing the methods of procedure of a general surgeon and those of a trained gynecologist when operating for pelvic inflammatory diseases.

Of course it is evident that the specialist should be as broad in his views as the general surgeon; and to be a good gynecologist nowadays demands the preliminary training of the general surgeon supplemented later by an especial study of the morbid conditions existing in certain parts of the body.

2. When should the aid of the gynecologist be sought by the general practitioner? Patients frequently come to the specialist who have been under the care of the general practitioner or general surgeon for varying periods of time, without having received any relief from the more or less expensive and more or less tedious treatment that has been carried out. Nor should these failures be a matter of surprise when we consider that the exact pathologic condition in not a few cases has been unrecognized, and that unless we start with the right diagnosis our treatment must always be vague and usually ineffectual. For the best interest, then,

---

* Read before the North Central Ohio Medical Society, at Mansfield, March 29, 1901.

of all parties concerned, the family physician no less than the patient, it would seem advisable, whenever a patient presents symptoms that suggest some pelvic inflammatory disease, and no improvement has taken place after a reasonable length of time from the course of treatment that is being pursued, a pelvic examination should be carried out by one who devotes his whole time to dealing with pathologic conditions of the pelvic organs. If such a procedure were carried out more frequently I have no doubt that many patients would be relieved before the local condition has had time to become more or less chronic. Again, there is no doubt that as a consequence of such an examination made at an early date many a patient would be spared an unnecessary routine of local treatment. It is no rare experience to meet with a patient who has undergone a long course of treatment for a supposed displacement of the uterus, and in whom careful examination (under anesthesia if necessary) shows that the organ is in a normal position. It may be argued that such a finding does not necessarily cast doubt upon the correctness of the original diagnosis, but even the most experienced among us will not hesitate to confess, that it is often difficult to recognize the true position of the uterus in certain cases, and that it is still harder to put the organ in its normal position. Under these circumstances one can hardly avoid the conclusion that a considerable number of women are treated for imaginary malpositions of the uterus. Perhaps a brief report of a few cases will serve to demonstrate the importance of the early recognition of diseased pelvic conditions.

Case 1.—Chronic adherent Salpingitis and Ovaritis: Mrs. K. K., aged 25, married six years; occupation, seamstress, nullipara; one miscarriage five years ago at three months. Her menses first appeared when she was 13 years of age; they have always been regular and painless, but scanty. She has had a profuse leucorrheal discharge. She has been complaining for the past five years of a sharp pain with soreness in the right lower abdomen, which is increased on exertion. Five years ago she was in bed for two weeks on this account; the pain has been much worse during the past year. She has also had a great deal of backache. The family history has no special bearing on the case.

On examination of the pelvic organs the following notes were recorded: The vaginal outlet is relaxed, the cervix is in the axis of the vagina. The uterus is forwards, enlarged, sensitive but movable. On the right side an adherent tubo-ovarian mass can be made out. The left tube and ovary also seem to be adherent. After a careful examination under anesthesia the adherent tubes and ovaries and the vermiform appendix were removed. This patient had been under the care of a general practitioner for over a year. Twice weekly, she had received local treatment and medicine for which she paid three dollars a visit. Her income was five dollars a week. Finally, she lost all confidence in her medical adviser and came to our clinic. By the surgical procedures that were carried out she was entirely relieved, although her condition at the time of the operation was far from satisfactory, as in addition to the local condition she had developed markedly hysterical symptoms. When she came to us her resources were so reduced that she was willing to have the operation postponed until she could make money enough to pay her hospital expenses. One can not but believe that this patient's prolonged suffering and reduced financial condition were undoubtedly largely due to the fact that the local condition had not been recognized.

Case 2.—Cancer of the Cervix: A. G., aged 58, IV-para; oldest child 33, youngest 19. Menopause at 43 years of age. Two years ago a large amount of blood came from the vagina. The flow ceased, however, within a few hours and no vaginal examination was made. In August, 1900, she began to have attacks of slight bleeding from the vagina, and during the past month she has been passing small quantities of blood at intervals of every few days. The symptoms that she presented when she came under our notice were the bloody discharge from the vagina, with general asthenia. On examination the outlet was found somewhat contracted; the cervix was flush with the vagina, particularly on the right side; the tissue of the cervix was friable, and even gentle manipulation caused a profuse hemorrhage. The uterus was enlarged. After an anesthetic had been administered, on pelvic examination the uterus was found to be of about the size of that of a two months' pregnancy. The cervical canal was dilated, and several ounces of a muco-purulent fluid escaped. The cervix was then thoroughly curetted and cauterized, and the cervical lips were brought together with ligatures after packing the uterus with gauze. Vaginal hysterectomy was then performed. On the right side of the vaginal wall it was necessary to incise the wall well up into the lateral fornix in order to get beyond the infiltrated tissue. In doing this the ureter was tied on this side. The patient, however, made a practically uninterrupted convalescence. On the day after the operation she began to have considerable distress in the right iliac region, and at this time we could detect a resistant globular mass in this region. No urinary discharge occurred from the vagina at this time, and she was serceting from 36 to 56 ounces of urine daily. On the sixth day after the operation the urine began to come from the vagina; the tenderness in the right side disappeared, and the amount of urine passed from the bladder now materially decreased. We believe that we had to deal with a transient hydronephrosis as a result of the ligation of the ureter, but that an uretero-vaginal fistula occurred.[1] With this exception the convalescence has been normal and so far as we can ascertain at the present time there has been no recurrence of the disease. On examination of the mass which was removed, it was found to consist of the dilated uterine body—which was practically a pus sac—and the cervix uteri which was involved in the cancerous growth. Microscopic examination showed a squamous-celled carcinoma of the cervix.

If this case had been examined at the time when she had the first hemorrhage some two years ago, the condition would in all probability have been suspected. No examination, however, was made until a few weeks before she came under our care although there had been two or three evidences of a bloody discharge in a woman who had reached the menopause some fifteen years before. This is one of the many instances of this condition that are overlooked until it is too late to do much beyond giving the patient a lease of life and relieve her of some discomforts. Such cases should be a warning to all of us, to take nothing for granted when a patient is bleeding from the vagina, be it ever so slight in amount.

Case 3.—Extra-uterine Pregnancy: Mrs. M. S., aged 35, married, III-para; oldest child 10, youngest 6. One miscarriage, eleven years ago at three months. The patient had been well until she was suddenly seized with a severe pain in the left lower abdomen, which was accompanied with a feeling of faintness, cold sweats and a bloody discharge from the vagina. When I saw her some three hours after the beginning of the attack the abdomen was somewhat distended. On vaginal examination a fluctuating mass could be palpated in the left side of the pelvis. The expression was anxious, the pulse was 120. We concluded that she was suffering from a tubal pregnancy which had ruptured into the broad ligament. We watched the patient for the next few hours, and, as she gradually improved, we determined not to carry out any operative procedures at the moment, preferring to wait until she became stronger. After a week had elapsed she entered the hospital, and an abdominal section was performed. A considerable amount of free and clotted blood was found in the abdominal cavity; there was also a tubo-ovarian mass on the left side as large as the closed fist, which was undoubtedly the gestation sac. This was removed. The tube and ovary on the right side were adherent, and after enucleation they also were removed.

---

[1] Careful examination failed to show any injury to the bladder. Three months following the operation the fistula closed.

The debris in the pelvis was wiped out and the abdomen was flushed with salt solution. We closed the abdomen without drainage after pouring into it 500 c.c. of a sterile salt solution. The patient made an uninterrupted convalescence. The microscopic examination confirmed the clinical diagnosis. This patient's condition had been early recognized by her attending physician, and he had at once sought additional help.

Such cases undoubtedly are frequently being met with by the general practitioner, in which the history is suggestive of an abortion or where the patient has missed several menstrual periods, and then suddenly has an attack similar to the one that we have just described. If such cases are examined at once and seen in consultation by a competent gynecologist, many lives would undoubtedly be saved by the immediate institution of the necessary operative procedures.

Case 4.—Double inflammatory disease of the Tubes and Ovaries with a sub-peritoneal Myoma of the Uterus: S. T., widow, aged 37, nullipara. For twenty years she has complained of a pain in the back, and for the past seventeen years, off and on, she has had a "neuralgic" pain in the left ovarian region. For five years she has had sharp pains at frequent intervals in the lower abdomen. During the past ten years she has had thirty attacks of pelvic peritonitis, which necessitated her staying in bed for from three days to two weeks at each attack. These attacks have become more severe during the last two years; the last one occurring in December, 1898. Three days prior to this attack I examined her and found a sub-peritoneal myoma as large as a fetal head. The small uterus could be made out beneath and attached to the myoma. The lateral structures were also adherent on either side. We advised that an examination be made under an anesthetic and the necessary operative procedures be carried out. The patient, however, would not give her consent. Three days later she had another attack of pelvic peritonitis. I attended her during this illness and after a two weeks' siege she recovered. She now concluded to submit to operative measures. On January 13, 1899, an operation was performed consisting of a myomectomy and a double salpingo-oöphorectomy, with removal of the vermiform appendix—which was slightly adherent—and the separation of many velamentous adhesions between the small and large intestines. The omentum was also adherent to the myomatous tumor and to the broad ligament. On the left side we had to deal with a hydrosalpinx and on the right a hematosalpinx. The lateral structures were released and removed after separating many strong adhesions. The patient made an uninterrupted convalescence and she is now well.

In all the years during which she had been suffering she had only been examined once or twice per vaginam prior to coming to us, and the physician had mistaken the myomatous tumor for the uterus. The only treatment that she had received was general massage, and a few applications of cotton tampons to the cul-de-sac. It seems hardly conceivable that such a condition of affairs could exist, and yet pass unnoticed, particularly as this woman had had so many attacks of pelvic peritonitis. Shortly before coming to us she had taken out a life insurance policy for $100,000, and I feel quite sure that no company would have been willing to have assumed this risk, if they could have known of the condition of the pelvic organs.

I could readily multiply these instances at great length, but I will not take up any more of your time by doing so. I am free to confess that the specialist makes mistakes, some of them grave, but one can not help but feel that in the very nature of things they must be rarer than those of the general practitioner whose attention from the study of special organs is so perpetually being distracted by his multifarious duties.

3. How can the general practitioner call in the aid of a specialist without detriment to his own interests and reputation? In the first place he can be assured that as a rule the patient will appraciate his efforts to do the best for her, whereas his mistakes and delays in calling in the aid of a specialist will be spread abroad by the patient, as soon as she discovers that other treatment might have proved beneficial long before. Loss of confidence in the family physician has far-reaching results and its effects can not be reckoned merely in dollars and cents. Secondly, it is easy for the general practitioner to guard his own interests by applying to a specialist, who is not only competent but who is a gentleman in the truest sense of the word. Again, often it will be found that no operative measures are necessary and in these cases the specialist will leave the patient in the care of her physician, and the latter can go on treating her with the full assurance that everything that is necessary is being done. As a specialist I can assure you that it is distasteful to me above all things to meet with patients who have lost all confidence in their family physician, especially when I see that the latter could have readily relieved himself of the responsibility without losing either in money or in professional reputation. One cannot but feel that the existence of full confidence between patient, family physician and specialist, is undoubtedly productive of the best results for all parties concerned.

702 Rose Building.

THE RATIONALE AND TECHNIC OF PNEUMATIC AURAL MASSAGE.

B. ALEX. RANDALL, M.A., M.D.

PHILADELPHIA.

The estimate of von Troeltsch that one-third of all adults are deaf in one or both ears has never been authoritatively questioned, and the extensive studies of school-children by Bezold and others have shown even in early life a serious loss in from 5 to 10 per cent. of all examined. As our clinical statistics prove that the great majority of these defects are due to impaired conducting apparatus and but a tithe to nerve-lesion, we are constantly facing the problem of how best to improve this conducting apparatus, both to check any progress of the defect and to regain, if possible, what has been lost. To this end the restoration of impaired mobility has long seemed a cardinal measure and hundreds of devices have been brought forward with more or less ardent claims as to their efficacy. The last word will not soon be said as to many of these, nor can any one man fully test them all; yet some twenty years of constant employment of various forms of massage has enabled me to form a fair opinion of the principles on which they must proceed and to recognize the fallacies which are too often presented in the advocacy of new candidates for acceptance.

Dealing with an apparatus essentially pneumatic, as is the middle ear, we naturally make most use of pneumatic massage for the desired mobilization; yet, just as the best efforts of the masseur upon stiffened joints elsewhere in the body are of slight avail in some cases until more radical surgical measures have broken up real or pseudo-anchylosis, so in the minuter field of the tympanum ruder means must at times have first employment. Cutting procedures should be resorted to only when the blunt force of probe and hook have failed; for the divided bands too often reunite into a worse hindrance than before. But the cotton-tipped probe can often do much to mobilize stiffened parts and rub in alterative ointments or solutions; and cases of long-standing post-suppurative deafness which had been abandoned by capable men as hopeless have years later been restored to a useful degree of hearing by gently vigorous massage of this sort. Lucae has obtained very good results with his spring-probe; but it is questionable how far its spring increases the efficiency in gentle hands or mitigates the rudeness of the clumsy. Usually painful, even after anesthesia has been attempted by ice or cocain, it can yet be borne by many patients, and will at times initiate an improvement which is unexpectedly marked as well as gratifying to the patient.

The various measures of pneumatic massage are likely to have the greatest vogue, however, both because of their gentleness, their wide range of applicability and their diagnostic value. Siegle's otoscope is the best, as it was also one of the first of these; although the dramatic value of electric or compressed-air manipulation will always appeal to some classes of patients and tempt the aurist who "must be up to date." Few modifications of the original apparatus have been for the better, except the substitution of a rubber bulb for the mouth-piece and lung power. Not only does this subserve convenience if the instrument is to be used by more than one person or in suppurative cases, but it materially increases its power, as is not infrequently desirable. A normal drumhead can bear a pressure of some fifteen pounds per square inch on either of its surfaces, and while this should rarely, if ever, be approximated in the practice of pneumatic massage, which has pathologic membranes to deal with, we may often need and use to advantage double the three or four pounds of negative or positive pressure which is the uttermost that the mouth can furnish. Siegle's fundamental principle, in which he advanced beyond his predecessors, must be adhered to—the variations of pressure should in almost all cases be made only in plain view; the massage must be made through an "otoscope"—and harm can then result from vigorous measures only in the most careless hands.

Injection of the manubrial plexus and other vascular areas must generally be induced by massage which is energetic enough to have any real efficacy; but this will usually be lost as quickly as it was evoked. The fear that is sometimes expressed that such injection will prove harmful by reason of exudation of leucocytes and increased sclerotic changes, is largely fanciful; such exudation need no more occur than extravasation. Either may readily absorb should it be produced, not only leaving behind no injurious trace, but really proving beneficial, by securing simultaneous absorption of previous exudates. All massage would fall under the same ban; but the oculist sees daily that corneal opacities can be best absorbed by massage with a stimulating ointment which shall cause not only marked injection, but actual new formation of vessels, thanks to which he secures absorption and replacing with better materials of the hasty repair-work which Nature had perpetrated. This is not so visible in other fields, but we know that it does take place; and the blood-count made after the general massage seance tells of a systemic plethora promptly induced, which is a large element of its usefulness.

It must be remembered, however, that in our aural massage the visible movements and injection of the drumhead are wholly secondary in importance to those induced upon the inner side of the tympanum. Much of the value of the procedure is in its mobilization of the stapes and to a less extent of the round-window membrane. Sometimes good motion of the malleus is obtained without improvement as to hearing or tinnitus, possibly because of laxity of the malleo-incudal or incudo-stapedial ligaments beyond the degree which Helmholtz pointed out as normal; but more often it is on account of anchylotic bands about the niches of the fenestra. At times such non-success is due to lack of air within the tympanum; for we must not forget that while we may speak of "sucking out the drumhead," in fact we merely permit the expansion of the air within by reducing the outside pressure. Tympanic inflation *per tubam* is therefore an absolute prerequisite in some cases, even some of those in which the slightest overdoing of inflation may be deleterious by concussion of a nervous apparatus already damaged by disease.

Besides the mechanical effect, then, of inflation and massage in mobilization, both measures can do good service through that very congestion which has been deprecated. The sclerotic tissues can at times be softened and stretched only after slight congestive exudation; and the cupping effect of the massage is no unmixed evil. It is a sharp-edged tool, not to be trifled with; but most surgeons ought to be able to trust themselves with keen instruments, if, indeed, such known potency for evil is not one of the surest incentives to safe and successful use. Measures supposedly harmless are usually but half-understood and perfunctorily used, and "didn't know it was loaded" applies to many things besides fire-arms. The blunt curette in removing cerumen and the forceps groping after foreign bodies are responsible for more injuries to the canal and deeper parts, with occasionally fatal results, than we ever like to believe. So we should study well during the massage, after it is finished, and at the next examination, with close inquiry as to the symptoms in the interval, if we are to know what we are doing for good or evil, and rightly to employ the massage for the benefit of the patient and the credit of ourselves and the profession.

As to the instrument, the original Siegle's otoscope has been little improved upon. It can be made of metal, with reduction of bulk and weight, and the speculum can advantageously be given the oval lumen, which best accords with the form of the canal—points which are well exemplified in Burnett's form of the instrument. The glass which closes the speculum externally may be plane or convex—the latter giving a valuably magnified image, but a proportionately reduced illumination. This matter of reduced light is cardinal and constitutes the great difficulty for beginners in using the instrument, especially if they are not accustomed to looking through the sight-hole of the brow-mirror. Much light is necessarily reflected from the glass, which is obliquely set so that this may not return to the observer's eye. Yet, many persist in staring at the reflection of the brow-mirror and so, not looking in the axis of the speculum, can see nothing else but its wall, instead of through into the ear. Of the light which does penetrate, only a fraction is reflected back from the fundus, and of this a further considerable portion is reflected internally, allowing but a small fraction to reach the eye. If the glass is convex, all of these losses are exaggerated and the resultant image, if enlarged two diameters, has but one-fourth the strength of illumination of the unmagnified view. Hence, there is need of precise adjustment of the light to secure the best possible illumination of the fundus before the speculum is introduced and of so holding the ear that one hand shall suffice for straightening and opening the canal and holding the speculum air-tight in place, while the other hand is free, first to manipulate the brow-mirror and make sure of the fullest lighting, and then to exercise through the bulb the precise suction and pressure desired. As with all other specula, the otoscope should be placed in the straightened canal and the ear drawn out over it as the speculum is pressed in.

Thus employed, the otoscope enables the physician to see exactly what he is doing, noting the response of the malleus-handle as well as of each part of the drumhead, flaccid or tense, to the variations of pressure. These can be made of any desired character by means of a good bulb, their frequency changing from twenty or thirty to three hundred to the minute, their amplitude equally diverse, while the pressure can be all positive or all negative, or alternations of each, with a maximum of nearly fifteen pounds in either direction, were such ever desired. No syringe or other form of "rarefacteur" can give more vigorous action nor allow such perfect control. The claim made for certain forms of massage-instrument that they *alone* can give some definite suction or pressure is wholly specious—any passable form of the apparatus can give a fair degree of either. It is urged as to some electric or other appliances that they give a definite rhythm not obtainable by hand-power; this is in a measure true and constitutes one of the advantages of the simpler apparatus, since such regularity of vibration is an element of decided danger, as is recognized in a hundred directions. Numerous devices embodying this rhythmic vibration have been proved seriously destructive of the vitality of nerves and other tissues—the electrically-moved tuning-fork will render cataractous the lenses of small animals kept near it—the electric plugger has been abandoned because it killed the dental pulp—and almost every form of "phono-massage" has proved damaging to the cases which at first seemed benefited by its employment. The faulty rhythm of the hand-masseur is therefore decidedly in its favor, and no mechanical device can compare in efficient control with the skilled hand guided by the intelligent eye. It has been shrewdly asked, whether this or that exploited apparatus was "as efficient under the table as on top"; certainly, the mental impression on the patient (surely not on the physician also) is no small part of the supposed potency of some of the "latest patterns."

Massage without ocular control is permissible only when the effect of the procedure has been well studied through the otoscope, and it has been proved harmless for the ear in question. Then, it may be given into the hands of the patient for frequent home-use as a valuable adjuvant to the more potent measures. For such employment there is some risk, however, in most of the "masseurs," such as that of Delstanche, as their cupping effect may be much over-done. "Finger-tip massage" can be used with hardly a possibility of mischief. the means is always at hand without cost, and it can be used inconspicuously anywhere at just the time when the need for it is felt. Hommel's "tragus-presse" can afford but little of the suction which is most useful to the depressed conducting apparatus; whereas the deeply-inserted finger can be withdrawn enough to notably rarefy the air and give the same alternations of suction and pressure which are most efficient under the otoscope. The hollowed palm placed over the auricle can in like manner exercise vigorous pneumatic massage. Other massage about the ear has been employed, most valuably that behind the ramus, which can slightly affect the deep-lying Eustachian tube; but it seems for this purpose inferior in value to vigorous gargling.

1717 Locust Street.

PERNICIOUS ANEMIA.

REPORT OF THE PROGRESS OF CASES PRESENTED TO THE ASSOCIATION IN 1900, AND REPORT OF A CASE WITH DIFFUSE SPINAL CORD LESIONS AND POST-MORTEM FINDINGS.*

FRANK BILLINGS, M.D.
CHICAGO.

(Concluded from page 488.)

Case 29.—This is an important and most instructive case, and is reported in detail with the postmortem findings, including a microscopic examination of the different tissues of the body.

Mrs. V. J.; aged 39; married; mother of four children; came to the Presbyterian Hospital, Chicago, on July 26, 1900. Her father is living, and has had stomach trouble a good deal of his life. Her mother died of paralysis. A maternal aunt died of cancer. There is one brother and seven sisters, all living and in good health. The patient has been obliged to work hard all her life, and has not been in good health since the birth of her last child. Two of her children are living and two are dead. One was still-born. The patient had typhoid fever when she was young, and suffered from malarial fever, as it was told her, two years ago. Her present illness began after the birth of her last child, seven years ago. There was indigestion, with gaseous eructations, acidity, fullness, and weight in the epigastrium after eating. Occasionally there was vomiting, but the vomiting had no relation to the meals. She never vomited blood. On several occasions she vomited bile after repeated attacks of vomiting. The appetite has been variable on the whole, but has been often good. There was diarrhea with watery stools containing undigested food for the first six years of her illness.

A years ago she commenced "christian science" treatment, and after six months the diarrhea ceased and she became much better. Recently there has been much irritation of the bladder, with a desire to urinate frequently. There has been a sense of pressure about the rectum, and at times some pain, especially if the bowels were constipated. There has been some difficulty in getting the bowels to move because of a sense of numbness in the rectum in the last few weeks. Menstruation ceased four months ago; the flow was scant for a month or two preceding the cessation. Her strength and endurance have been gradually lost. She was overworked during most of the illness, but her legs became finally so weak that she was obliged to remain in bed on and after December, 1899. She and her friends noticed that she was paler than usual, and that the skin had a yellowish tinge. This has increased since she has been in bed. She has noticed that her legs have become much weaker since she went to bed, and that she has not complete control of the bladder. The bowels have usually been constipated and required a laxative or the injection of water into the bowel to move them.

---

* Read at the meeting of the Association of American Physicians, at Washington, D. C., April 29, 1901.

An examination showed a woman fairly well nourished; the skin was very pale and of a distinct yellowish tint. The mucous membranes of the lips and mouth were pale. The tongue was indented and furred. There were no carious teeth; the lungs were negative. The heart area was normal. There was a soft systolic blow in the mitral and pulmonic areas. The radial pulse was about 100 per minute, and was small and soft. There was diastasis of the recti abdominalis muscles. The belly was "pot-form." There was very palpable visceroptosis, including the liver, kidneys, spleen, intestines and stomach. The uterus was retroverted and moderately fixed. Some pain was caused by an attempt to restore it to the normal position. The body of the uterus was small, and a small nodule was felt in its posterior surface. The rectum was normal; the eye grounds were normal. The patient had abrasions of the skin over the sacrum, and lay partly upon the side with the thighs and legs flexed. There was some atrophy of the muscles of the lower extremities, chiefly of the extensor groups. The knee-jerk was increased. There was a slight ankle clonus, more marked in the left than in the right foot. Babinsky's sign was present in the right, but not in the left. Sensation was diminished in the lower extremities, most marked in the feet and legs, and almost normal in the thighs. The muscular sense was noticeably absent. The patient could perceive pain, and in certain areas of the leg could distinguish heat from cold, but in others heat was felt as pain and cold was felt as touch only. There was a small area in the left inguinal region and upon the outer surface of the right thigh, where tactile sense was diminished and heat was felt as pain. There was noticeable loss of power in the legs and thighs, which was more marked in the right than in the left. There was loss of power in the rectum and bladder. The muscular power and the sensation of the skin in the upper extremities seemed normal. She complained of a sense of constriction about the abdomen, beginning at the waist-line. The urine, with a specific gravity of 1012, was acid in reaction; no albumin nor sugar present, and was microscopically negative. The blood examination showed hemoglobin , 20 per cent., red cells, 610,000, and white cells, 3200 per cubic millimeter. Poikilocytosis was very marked, and nucleated red cells, with megaloblasts predominating, were found. (See Chart No 5.)

The patient remained in the hospital from that time until the date of her death on Feb. 27, 1901. During that time many blood examinations were made, as indicated in the accompanying chart, which showed two waves of improvement while under observation, and the death of the patient occurred during the last wave of improvement. The blood findings were all characteristic in every way of pernicious anemia. The interesting point in the case is the spinal cord involvement, which consisted of a paraparesis, noted at the time of admission, and which gradually increased up to the time of her death. There was finally complete paralysis of the bladder, and in consequence, an infection which extended to the kidney, and the patient died of septicemia dependent upon a pyelonephrosis. This was possibly aggravated by extensive bed-sores, which increased in extent and depth in spite of the greatest care.

The stomach contents were examined after test meals on several occasions, and hydrochloric acid was found absent in every instance. The stools were examined and found negative as to parasites. The urine, after the infection of the bladder, became alkaline; and contained considerable pus and many bacteria. The character of the bacterial infection was not discovered. During the greater part of the illness the temperature of the patient ran an irregular course of either a remittent or intermittent type, but it was never severe in degree. The pulse was usually rapid and small, and there was always a complaint of great weakness and of breathlessness upon exertion. The nourishment of the patient remained good throughout the whole illness. Her appetite was usually good, and although digestion was not perfect, assimilation of her food occurred. About the middle of January, 1901, the infection of the bladder and of the kidneys occurred, and from that time the patient suffered from an intermittent and remittent type of fever of severe degree, and at times was delirious, apparently from the fever. Five days before death the temperature fell below normal and remained so until death, and for two days preceding that occurrence it registered from 93 to 94 F. in the rectum. The pulse and respiration fell with the temperature, and the patient died with a very low tempera-

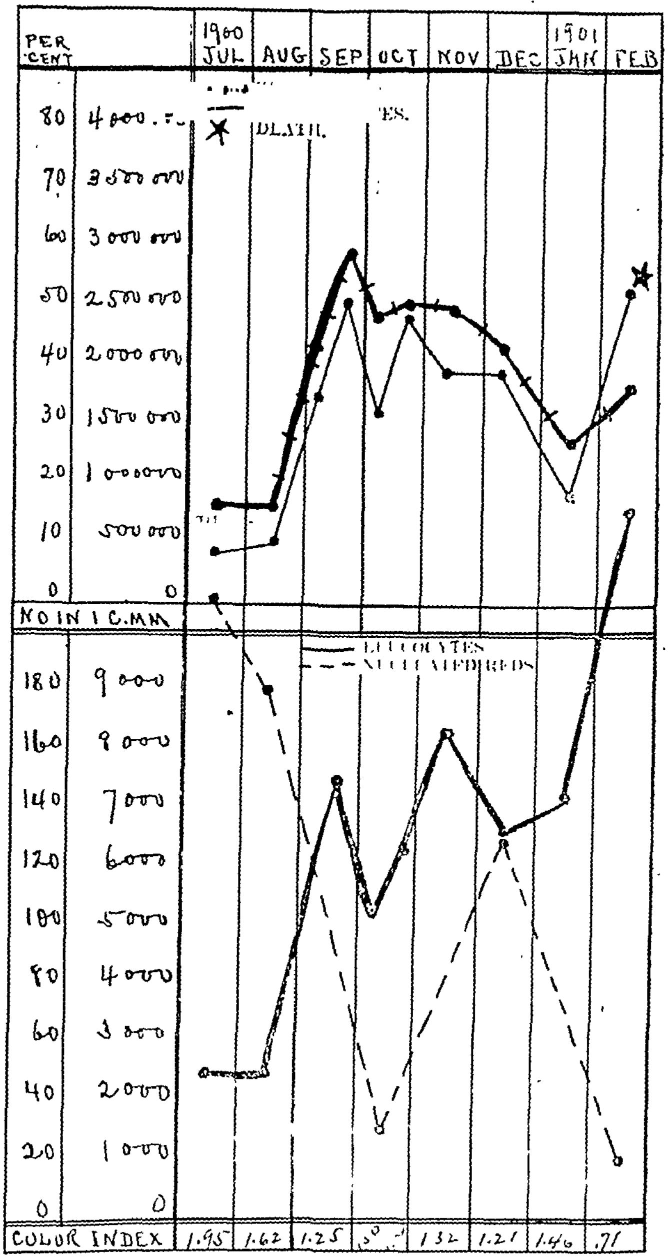


CHART 5.

ture, slow pulse and slow respiration. At the time of death the blood findings indicated a wave of improvement, and just at death there was a terminal leucocytosis.

The postmortem examination was made by Professor Hektoen, at the Presbyterian Hospital, on Feb. 27, 1901, when the following diagnosis was made: General anemia; red marrow in femur; splenic hyperplasia; degeneration of posterior columns of spinal cord; ascending cysto-uretero-pyelonephritis, with necrosis of the medullary papillæ; broncho-pneumonia; fatty liver; thrombosis, with softening of the inferior vena cava and continuation to the left in the renal vein; sclerosis of aorta; chronic pelvic peritonitis; with tubo-ovarian adhesions; extensive sacral decubitus, and edema of feet.

The body, which is still warm, is that of a rather middle-aged, poorly-nourished woman. There is no rigor mortis, and no posterior lividity. There are huge bed-sores with great undermining of the skin over the sacrum, exposing the coccyx and lower part of the sacrum and the left trochanter. The limbs are fixed, the knees somewhat flexed and the feet, especially the left one, slightly edematous. The sclerotic coats, especially that of the left eye, show traces of recent hemorrhage.

The abdominal cavity is empty, and peritoneum smooth. The pleural cavities are empty and smooth. The mucous membrane of the gums is intact. The tongue, in its anterior roof, shows branching fissures; its mucous membrane, as well as that of the pharynx, esophagus, larynx and trachea, is normal. Peribronchial glands are normal. The lungs are pinkish externally and but little pigmented; they are soft, spongy and crepitant. The cut surface is pinkish and bloodless. In the lower lobe of the right lung there are several areas of recent lobular consolidation, from which a thin, purulent fluid can be expressed. In this lobe the bronchi also contain muco-pus. In the upper lobe there are one or two small black, subpleural concrements. The heart weighs 250 grams. There is considerable amount of subepicardial fat. The cavities are somewhat dilated and contain a small amount of fluid blood; their walls are thin and flabby; the myocardium is normal. In the left ventricle there is an aberrant tendinous cord, which crosses the cavity in the lower half. There is no evidence of fatty degeneration in the myocardium. The beginning of the pulmonary artery is smooth. The right shows several yellowish areas, the largest one being in its descending portion. There is an obliterating thrombus of the inferior vena cava, beginning opposite the fourth lumbar vertebra and extending downward to the iliac veins and the right side into the femoral vein and its branches almost to the knee. The thrombus in the left iliac vein is red, in places grayish, with extensive puruloid softening.

The spleen weighs 350 grams; its external surface is smooth and of a slaty color; the capsule does not wrinkle. The cut surface is of true reddish-gray color; its consistence is quite firm; its connective tissue being visibly increased. The Malpighian bodies are not visible except in a few places.

The liver weighs 1800 grams. There are a few perihepatic adhesions binding it to the diaphragm. It is yellowish in color both externally and on the cut surface. On section the peripheral parts of the lobules appear much yellower than the central portions. The bile passages are patent. The gall-bladder contains a quantity of very thick, viscid, tarry bile, and a number of small faceted calculi.

The pancreas is normal in size and appears normal on its cut surface.

The stomach is small and contracted; its mucous membrane was not examined. The stomach was filled with formalin for histologic purposes. The mucous membrane of the small intestine is intact, and apparently not greatly atrophic; that of the large intestine and rectum is normal. The vermiform appendix is also normal.

The kidneys are enlarged, weighing together 520 grams. Their external surfaces, particularly that of the right, show roughening of the capsule, with yellowish spots, some of them purulent. The pelvis of each is filled with turbid, thick pus, in which there are many necrotic masses. The mucous membrane of the pelvis is thick and in places ulcerated and irregular. The apices of some of the medullary pyramids are distinctly necrotic, being capped by a yellowish, rather firmly adherent eschar. In some places this has fallen off, leaving ulcers. The calices appear dilated and lines of suppuration extend upward into the medullary pyramids and into the cortex. In the pelvis of the left kidney there is a firm, yellowish, adherent thrombus in the branches of the renal vein. The ureters are thickened and somewhat dilated; their mucous membrane is roughened and covered with pus. The urinary bladder is contracted and its walls thicker than normal. Its cavity contains a small quantity of turbid fluid. The mucosa is roughened and in places is diffusely red and hemorrhagic.

The right ovary and tube are small and shrunken and embedded in adhesions. There are adhesions about the left ovary and tube, among which there is quite a large collection of serous fluid. The uterus is about normal in size. Its mucous membrane is smooth. There is a bilateral, old cervical tear. The vagina is normal.

The skull and membranes of the brain are normal. There is an excess of cerebrospinal fluid; in the lower part of the spinal cord there are numerous minute, bony, white scales in the meshes of the pia arachnoid. The cord is about uniform in consistency throughout. On cut section there is distinct degeneration in the posterior internal columns. In the lower part of the cord this degenerated area becomes wider and more irregular.

The marrow of the left femur is deeply red throughout and quite cellular. Smears contain megaloblasts, normoblasts, etc.

Histologic examination was made by Mr. Robinson, in the laboratory of Prof. Ludvig Hektoen, and by Dr. J. F. Smith, of the House Staff of the Presbyterian Hospital.

Lungs.—Sections from the more solid portions of the lungs show marked degeneration; quite extensive destruction of the alveolar walls, with the alveolar spaces of the large portion of them completely filled by disintegrating leucocytes and a serous transudation. In the remaining part the consolidation is much less complete. The alveoli are occupied and the character of the material within them somewhat different, the serous portion being much more abundant and the leucocytes fewer in number. A considerable amount of blood can be seen along the lines of the broken alveolar walls in the denser portions of the sections. The smaller capillary vessels are also highly congested, and the larger vessels, whose walls show evidence of degeneration in their granular and fragmentary appearance, are distended with serous material.

Heart.—The muscular fibers under high power of the microscope present a peculiar appearance. Along the margins the protoplasm appears normal, with its transverse striations distinctly visible, while the central portion in many places is pale and degenerated and shows no transverse striations. This gives to the fibers somewhat the appearance of a separation into two longitudinal divisions. Many of the fibers show a longitudinal splitting into fine threads. The nuclei stain well, but the protoplasm throughout shows some irregularity on staining. Bands of light color cross the fibers transversely. Many of the nuclei are large and irregular.

Femoral Vein.—Sections of this vessel show the wall varying considerably in thickness in different portions, containing but a scant amount of muscular tissue. The lumen is occupied by a large mass of fibrin and disintegrated blood, the central part of which is less dense and more granular, being composed largely of degenerated cellular elements. Around the margins of the mass some evidence of proliferation of the fixed tissue cells is seen, and in a few places there are growths starting inward from the vessel wall. No bacteria can be found in sections stained by Gram's method.

Spleen.—The Malpighian bodies are very indistinct throughout the greater portion of the section, and in some places entirely invisible. The splenic tissue in all parts of the section obscured by the presence of an enormous amount of blood. The nuclei of the cells are visible, stained quite deeply, but their protoplasm is pale. The capsule of the organ is thickened and the connective tissue within is notably increased in amount, but it has a peculiar granular, disintegrated appearance, which is seen also in the walls of the vessels included within the larger trabeculæ. The blood vessels show some increase in thickness of their walls and lumens, in most instances engorged with blood. The elastic tissue fibers are much increased, as shown by Weigert's special stain.

Liver.—Sections of the liver show extensive fatty degeneration, particularly in the peripheral portion of the lobules, where the liver cells are almost entirely replaced by fat vacuoles. Only a very scanty amount of protoplasm and a few poorly stained nuclei remain. Immediately surrounding the central vein of the lobule there is, in most cases, a small area of liver tissue, almost free from fat, showing, however, evidences of degeneration by the dull color and granular character of its protoplasm and by the pale staining of the nuclei and the presence of some granular detritus in the spaces between the cell columns. The capsule of the organ is not thickened, nor is the interlobular connective tissue apparently increased in amount. The bile ducts are not proliferated. Some of them are large and have wide-open lumens. The blood-vessel walls show no particular changes; the lumens are occupied by varied amounts of true blood. Staining with ferrocyanid show small amounts of granular iron here and there in the interstitial tissues. Staining by Adami's carbolthionin method show many diplococcus-like bodies located within and between the liver cells.

Pancreas.—Sections of this organ stain well and show no apparent abnormality more than a congestion of some of the smaller blood vessels and perhaps a slight increase in the thickness of their walls. The lobules are distinctly marked off. Numerous bodies of Langerhans of various size are present throughout the section.

Stomach.—Sections of the fundal portion of the stomach show marked thinning of its wall, particularly of its mucous and muscular layers. The glands of the mucosa are few, shallow, and atypical and the epithelial cells of their lining are very indistinctly marked off and poorly stained. Round-cell infiltration is present. The submucous layer is comparatively thick. Most of its vessels are congested. The muscular layers are thin and pale. Practically the same may be said of sections very near the middle of the lesser curvature of the organ. Muscular tissue, however, is more abundant and the thickened vessel walls in the submucosa are more evident. In sections from near the pylorus atrophic changes are not seen. Mucosa is normal in thickness and appearance, and the muscular layers, white, dense and well stained. On the inner surface and in the lumens of the more superficial glands are seen bacterial colonies.

Intestines.—The intestinal tract in its upper portion, that is, the duodenum and jejuno-ileum, shows no marked pathological change. Walls of the ileum, particularly in the region of the cecum, are rather atrophic, especially its mucous layer, which in places is reduced to a narrow band, with but slight resemblance to mucosa. There is diffuse, round-celled infiltration of the mucosa. The submucosa, in places, is congested and edematous. Numerous mast-cells are seen in the submucous layer.

Kidneys.—Sections of the kidney show marked destructive changes toward the apices of the pyramids. The surface bordering on the pelvis is composed of typical granulation tissue infiltrated by large numbers of polymorphonuclear leucocytes. There is diffuse, almost universal, edema and leucocytic infiltration of the somewhat increased interstitial tissue and congestion of the capillary and larger vessels. Throughout the section are granular necrotic areas of variable size and minute abscesses. A large proportion of the tubules in both pyramidal and cortical portions are dilated and packed with masses of polymorphonuclear leucocytes embedded in a granular debris. In many places the cells have undergone complete necrosis, involving also the lining epithelium and peritubular connective tissue. The straight tubules, even where densely packed, often have an intact epithelium with clear nuclei. In others it is flattened, degenerate, or necrotic. The glomeruli have somewhat thickened capsules and are much congested. Others yet show carious degenerative changes, not a few being entirely necrotic and granular. In some places glomeruli and tubular contents have dropped away during the handling of the sections, leaving only the thickened connective tissue framework.

Spinal cord.—Sections of the cord, stained by the Weigert-Pal method, show degenerative changes, with absence of myelin sheaths from many of the tracts; at some levels comparatively few sheaths are present in any part of the transverse section, and their absence from the postero-median and crossed pyramidal tracts is more or less complete at all of the levels examined.

It was intended to give illustrations of sections of the spinal cord at different heights, to show the site of the degenerative changes in the cord. Sections made of the medulla and pons show degeneration of certain tracts here, as well as in the cord, and it therefore seems wiser to postpone the report upon the histology of the cord until a more extended examination may be made including the entire cerebrospinal system. This will be the subject of a future report to the Association.

The changes in the spinal cord in this case are the same, apparently, as those reported by others, and consist of degeneration in the postero-median, the pyramidal, the direct cerebellar and Gower's tracts. Diffuse degeneration appears in this case in the cervical and upper dorsal cord. It seems, therefore, in this case, that while the degenerative changes are limited to certain columns in some parts of the cord, especially in the lumbar, dorsal and upper cervical, it become more diffuse, as noted above, in other portions of the cord. One of the peculiar conditions noted is the absence of shrinkage in the degenerated tracts. Possibly this may be due to the shorter course of the disease as compared with the more chronic cord lesions of locomotor ataxia, lateral sclerosis, etc.

Bacteriological examination.—Media inoculated from the heart's blood showed no gross changes, either by aerobic or anerobic methods of cultivation. No cultures were obtained from the lungs. Upon an agar slant, inoculated at the autopsy from the thrombosed femoral vein, there developed a pure culture of the bacillus coli communis. Upon agar-agar plates from the liver there appeared a number of small, white colonies, composed of small cocci which, stained by Gram's method, produced a moist, whitish growth on glycerin agar, a dirty brownish-white growth, with discoloration, on potato, no apparent change in litmus milk, no gas in glucose agar, and no liquefaction of gelatin. From the kidney were obtained cultures of small cocci which, stained by Gram's method, and in subcultures, produced growths characteristic of staphylococcus albus; also small, bluish-white colonies of small oval bacilli, which were almost completely decolorized by Gram's method of staining, produced a scanty moist growth upon the surface of glycerin agar, a brownish growth with discoloration on potato, gas in glucose agar, apparently no alkalinity on litmus milk, and a funnel-shaped liquefaction of gelatin.

100 State Street.

NOTES ON ANESTHETICS.

D. H. GALLOWAY, M.D.

CHICAGO.

A man can not do two things at once so skilfully as he can do either one of them by itself. A surgeon can not do his most skilful operating while devoting half his attention to the anesthetic.

A surgeon is frequently more concerned about the result of the anesthetizer's work than he is about the results of his own work.

Constant anxiety about the anesthetic divides the attention of the surgeon between what he is doing and what some one else is doing and must hinder the progress of the operation.

In many cases more skill is required to administer the anesthetic than is required to do the operation.

An operation may be practically devoid of danger; an anesthetic is never administered without jeopardizing the life of the patient.

In more than half of the cases the patient is in greater danger from the anesthetic than he is from the operation.

A good anesthetizer need not necessarily be a good surgeon; neither are all surgeons good anesthetizers.

Death from an anesthetic may occur in the hands of the most skilful anesthetizer, but in the great majority of cases in which deaths have occurred the anesthetic has been in the hands of the unskilled.

The patient should not be brought profoundly under the influence of chloroform in less than five minutes; more than ten minutes is almost never required.

In administering chloroform there is seldom a stage of excitement except the patient is addicted to the use of alcohol, tobacco or some other drug.

The skilled anesthetizer seldom, if ever, touches the globe of the patient's eye with his fingers; it is unnecessary and may do much damage.

The anesthetizer should be considered a consultant to the surgeon, rather than his assistant; it is as important that he be an expert in the giving of anesthetics as that the surgeon be an expert in operating.

The surgeon can not do any operation of consequence and administer the anesthetic too; therefore, the patient should be made to understand that at least two men are required and that they are equally entitled to pay for their services.

The anesthetizer's fee should not be contingent on the surgeon's fee any more than the consultant's is, and, like the consultant, he should send a separate bill for his services.

The anesthetizer must not forget that the anesthetic is to be given on account of the necessity for surgical operation and that the reverse is never the case; hence, the anesthetizer's position is of necessity subordinate to that of the surgeon. As a rule the anesthetizer must use the anesthetic selected by the surgeon, though when anesthetics are administered only by skilled men it is probable that a selection of the anesthetic will be left to the anesthetizer.

No man can safely administer an anesthetic and watch the operation at the same time; if a death occurs while he is so engaged he should be held guilty of criminal carelessness.

During anesthesia the patient's life is in continual and imminent danger and his safety depends not only on the skill of the anesthetizer but also on that person's constant and undivided attention. The indifferent or inattentive person has no business with anesthetics.

Clinical Report.

CASE OF TUBAL PREGNANCY.

H. W. HENDRICKSON, M.D.

MONTEVIDEO, MINN.

On April 18, 1901, at 8:45 p. m., I was summoned to attend Mrs. E. P. H., whom I found in collapse, practically pulseless and suffering agonizing pain in the abdomen, especially in the right epigastric region where a large and hard swelling could be outlined.

A diagnosis was made of tubal pregnancy, with rupture and escape of the ovum, and hemorrhage into the peritoneal cavity. The gravity of the situation was at once explained to the family, and preparations made for immediate laparotomy.

At least a gallon of clotted blood was evacuated; a 12 weeks fetus with membranes was removed, the tube ligated and its distal portion with the ovary included detached and removed. The abdominal cavity was irrigated with a normal saline solution, and the wound closed without drainage, rigid asepsis having been observed throughout. Before the operation a hypodermoclysis of 3 pints of normal salt solution was administered, and a like amount was given after the operation was completed; the sites chosen were the cellular tissue under the breasts on both sides. The pulse just before the operation and after the first dose of saline solution had been given was 150 and very feeble. At 4 a. m. next day it was 140 and stronger, and at 10 a. m. 120 and fairly good. The woman made an uninterrupted recovery, and her temperature did not at any time show a rise of more than two degrees above the normal. The effect of the saline injection was very striking, and I am quite certain that but for its timely administration this patient would not have rallied from her double shock, namely, from the hemorrhage and subsequent operation.

Dr. Cabanes, of Paris, has offered to install and maintain a museum of retrospective medicine at the Paris Faculté de Médecine.

TUBERCULOSIS AND HOUSE INFECTION.

The question of house infection by tuberculosis is a rather important subject, but one that heretofore has not been extensively studied in a statistical way. There has been an abundance of proof that invalids with the disease can temporarily infect their surroundings, and that dark and ill-ventilated tenements in the slums can retain the infection to all appearances. There have, however, so far as we are aware, been but very few exhaustive comparative studies of house infection under varying conditions as to sanitation; this alone can be considered a satisfactory method of investigation of this subject. What we want to know is not merely how far and how long tuberculosis germs can retain their vitality and virulence under specially favoring conditions, but how they exist and behave under ordinary and average ones, and also in those of better than average as regards general hygienic surroundings. A paper read at the late tuberculosis congress Dr. Harold Coates[1] deals with this subject somewhat in the desirable way, though the inquiry was limited in its scope. He divided the dwellings investigated into three classes: 1, those in a dirty condition, where careless consumptives lived, who took no precautions to prevent infection; 2, very clean houses occupied by rather careless consumptives using insufficient precautions as regards sputa, etc.; and 3, dirty houses where there had been no case of tuberculosis for years. In every case the condition was noted as to air space, light, ventilation, construction of walls and freedom from dust and dampness, presence or absence of carpets, curtains, etc., and length of residence of patient and duration of illness.

Twenty-one houses of the first class were examined. In 13 of these at least one animal was found tuberculous, and, in another, tubercle bacilli were found in the dust, making 14 out of 21, or 66 per cent., giving positive evidence of infection. In 7 houses there was no evidence that the dust was infective. In 8 of the 14 infected houses the lighting and ventilation were bad, in 1 fair, and in 5 good. In none of the 7 giving negative results was it poor or bad. Fifty-two guinea-pigs were inoculated with dust from these houses; 20 of these died shortly after being inoculated, 32 were killed four or five weeks after and 17 found to be tuberculous and 15 healthy.

Ten clean but infected houses were examined and infectious dust was found in 5. The average cubic air space in these, per individual, was 336 feet; in the other 5 it was 506 cubic feet. Of the infected houses only one had good light and ventilation, while these were good in all the non-infected houses. Ten dirty tenements without consumptive inmates were tested and in none was tuberculous dust obtained. Dust taken from the waiting-room of the out-patient department of the Manchester Hospital for Consumption, a lofty, well-lighted and ventilated hall used daily by 180 patients, was also tested, with negative result.

These results agree pretty closely with those of Cornet in Berlin, but are slightly more favorable. They point very strongly to the conclusion that the prime disinfectants for tuberculous germs are light and air, and that with free admission of these and proper care there is little danger of permanent infection of dwellings. They also demonstrate that without these, thorough cleanliness will not protect from infection from a careless expectorating consumptive. The particular danger of tuberculous houses is in the crowded districts of the cities, where light and ventilation are often apparently the last thing thought of in the construction of tenements, not only of the poor, but also those of the flat-dwelling middle class.

FUNCK'S SPORIDIUM VACCINALE.

The cause of smallpox and vaccinia has not been satisfactorily demonstrated as yet. The most recent investigations in this field are those of Funck, of Brussels, whose results have attracted considerable notice, the organisms described having been used by Gaylord, for instance, as prototypes of the protozoon of cancer that he claims to have discovered. Funck,[1] in his last article, attempts to show that he has fulfilled all the requirements necessary to prove that variola and vaccinia are caused by the same parasitic protozoon. In the first place he develops the fact that vaccine, at first usually rich in bacteria, eventually undergoes a process of self-sterilization, retaining, however, its power to produce typical vaccine pustules. Hence, he concludes that the active agent in vaccine lymph is probably not a bacterium.

This conclusion remains open to the criticism, however, that the active properties may be of bacterial origin. When lymph is examined microscopically in hanging-drop preparations mixed in bouillon certain cysts filled with spores as well as free spores are easily recognized at the bottom of the drop, whereas epithelial cells and cellular debris rise to the upper surface parts of the drop. The cysts are round or egg-shaped, 25 microns in average diameter, and the spores are from 1 to 3 microns in diameter and have ameboid movement. The cysts stain with sudan. Epithelial cells with parasitic inclusions are also seen. On account of the ease of observation and characteristic form, Funck finds it quite remarkable that these elements have not been recognized earlier and more generally. They were undoubtedly described by L. Pfeiffer in 1887 and by him referred to the sporozoa; for this reason Funck proposes the name sporidium vaccinale. In order to secure pure growths of the organisms, Funck spread sterile lymph in bouillon upon the surface of agar plates and after a time removed the cells which had risen to the surface of the drops; whereupon the cysts were fished out by means of a flattened platinum wire and mixed in broth. Inoculation of calves with this broth gave characteristic pustules and produced full immunity against ordinary vaccination. Funck claims that he thus secures the cause of vaccinia in pure form, but it is evident that he has not excluded, 1, organisms too small to be recognized, and 2, ferments and other substances that may be dissolved in the lymph and still carry the active properties. The bouillon emulsions of so-called cysts can not be regarded as the equivalent of pure cultures in the bacteriologic sense and capable of giving rise to innumerable subcultures by inoculation and multiplication. Funck found the same bodies in the pustules of variola and concludes that variola and vaccinia are both caused by sporidium vaccinale. Even from the purely morphologic standpoint it is probably rather doubtful if the bodies described by Funck are sufficiently characteristic to be regarded as other than the product of cellular degenerations and other lesions.

GLOBULICIDAL ACTION OF URINE.

Laking of red corpuscles may occur from different causes. It takes place in solutions of less concentration —hypotonic—than the blood serum, and also under the influence of certain toxic substances no matter if the concentration of the fluid medium is quite the same as the blood serum—isotonic. It has been found that under certain conditions the urine may cause the laking of blood. This may be because the urine is hypotonic, but it may also depend upon other factors.

Indeed, there may be hemolytic substances in the urine which seem to be prevented from causing hemolysis because of the hypertonicity of the urine, as Hamburger and, following him, Camus and Pagniez,[1] showed by adding a few drops of urine to non-hemolytic solutions of sodium chlorid (0.66 to 0.70 per cent.) and mixing in a few drops of blood. After an hour or two in the incubator more or less laking may take place. Camus and Pagniez show that under these circumstances normal urine is hemolytic for the corpuscles of the rabbit, the hemolytic property disappearing, however, on alkalinization.

From their experiments it would seem that hippuric acid plays an important rôle in the laking of rabbit's blood by human urine. Under pathologic conditions neutral or alkaline urine may be globulicidal, and as this power generally diminishes on heating to 55 C. for some minutes it may be dependent on the passage into the urine of certain ferments or alexins from the serum of the blood. Generally human urine, although markedly globulicidal for rabbit's blood, is without effect upon human corpuscles. Occasionally, however, human urine lakes human blood. Ascoli,[1] and Camus and Pagniez have observed such instances, and at least in some cases the laking has been due to other causes than hypotonicity. This may explain certain cases of hemoglobinuria occurring without hemoglobinemia and of urinary origin. Camus and Pagniez cite the case of a chronic nephritic whose urine had a freezing point of 0.79 C. and which showed the spectoscopic bands of oxy-hemoglobin. The blood serum did not contain hemoglobin in solution, but the urine quickly laked corpuscles from the patient's blood. In this case the urine was distinctly hemolytic and thus caused laking of the blood which entered the urine at some point or other of the urinary tract.

GENERAL INFECTION WITH GONOCOCCUS.

Recent investigations with the aid of modern methods have shown conclusively that the gonococcus may invade the general circulation and cause an acute endocarditis, which usually assumes a malignant, destructive character. This demonstration, among many others one might cite, is an excellent illustration of the advantages that result from efforts to determine the exact nature of inflammatory and infectious processes by placing the diagnosis upon an etiologic basis. Our respect for the gonococcus and for vulgar gonorrhea has increased greatly since the pathogenic possibilities of micrococcus gonorrheæ have been shown to equal those of the most virulent of microbes. Recently, Prochaska has described additional cases of general gonococcal infection from Professor Eichhorst's clinic in Zurich.[2] In one case gonococci were demonstrated by microscopic and cultural methods in the endocardial vegetations of a young man in whom polyarthritis and acute aortic endocarditis developed soon after onset of an ordinary gonorrhea. In this case bacteriologic examination of the blood during life gave a negative result, but in two other instances of arthritis in the course of gonorrheal urethritis, both of which left the hospital greatly improved, cultures from the blood in ascites bouillon and ascites agar gave typical growths of gonococci. The use of several cubic centimeters of blood, drawn directly from the veins at the elbow and inoculated into large quantities of ascites bouillon is recommended as the surest method for obtaining positive results.

Wassermann[3] also demonstrated gonococci both morphologically and culturally in the endocardial vegetations of a fatal case of gonorrheal cystitis, prostatitis, nephritis and endocarditis. In the interests of a definite differential diagnosis upon an etiologic basis cultures from the blood should be made as indicated in all cases of gonorrhea complicated with joint inflammations and other clinical evidences of general infection. If practiced in the early stages this method will undoubtedly settle definitely the gonorrheal nature of many of the joint infections now regarded as gonococcal upon ordinary clinical evidence only.

JOURNAL OF MEDICAL RESEARCH.

The old *Journal of the Boston Society of Medical Sciences*, a high-class publication known to and duly appreciated by only a limited circle of the profession, has ceased to appear under its former too modest form, and comes out with a new title and a new dress. *The Journal of Medical Research* is a handsome octavo, well fitting the quality of the matter contained, and it will soon rank among the leading scientific medical publications of the world.

PECUNIARY VALUE OF A WOMAN'S LIFE.

Coming down to the question of a woman's relative worth in dollars and cents as compared to that of man's, the courts seem to give man the best of it. In our Medicolegal Department this week is recorded the decision of two state Supreme Courts which put a woman down as being worth but one-half as much as a man, by inference at least. It is generally accepted in all courts that a man's life is worth $5,000 at least, and this amount is usually given in a verdict for damages in case of death. But a court in Maine rendered a verdict of $3,500 in a case in which a woman's life was sacrificed, and the Supreme Court cut it down to $2,500. Likewise in New Jersey, the Supreme Court reduced a $5,000 verdict to $2,500. Hence, we presume a woman is hereafter to be considered worth $2,500, while her husband will bring twice that sum. If Mrs. Catt and her followers do not rise and indignantly protest, they certainly ought to do so.

DEATH CERTIFICATES AFTER QUACK TREATMENT.

If every death occurring under treatment by mental healers, "christian scientists," and other delusions and forms of quackery, was made a matter for a coroner's inquest and properly investigated, there would be fewer patrons of these humbugs. Too many physicians are sometimes good-natured and careless enough to give a postmortem diagnosis and death certificate in such cases, thereby directly aiding humbugs and frauds. A physician can not well refuse a call for help while life lasts, but this writing of death certificates upon the work of quacks is another matter. While such is sometimes unavoidable, there is no reason why any physician should step in and deliberately help out of his difficulties one who is not only hostile to rational medicine, but who is also in this regard a public enemy. An inquest is an unpleasant thing and trying to the feelings of an afflicted family, but if it would prevent their giving cause for it in future cases by employing Eddyites, Dowieites or quacks, it might be the greatest boon that could be conferred upon them. The matter is one in which the physician, called too late to aid the living, should consider his responsibility.

DIPLOMA MILLS.

The medical diploma green-goods men are still at work, though the notorious Armstrong and one or two others are out of the business, it is to be hoped permanently. The latest developments are the exposure of the Norton-Smith diploma mill in Jersey City and another similar one in Chicago, which dealt, however, more particularly in Divinity Doctorates, and the profitable existence of which is a scandal on the clergy, or those few of that profession who were morally and mentally weak enough to patronize it. Perhaps we might also note here some recent charges as to the dental diploma frauds, but that matter is not at present at a stage where one can speak positively as to the truth or otherwise of the allegations. As regards the New Jersey case there is little opportunity to doubt the fraudulent intent, the wording of the circulars and imitation-typewritten letters permits of no doubt. Through various correspondents and readers THE JOURNAL has been favored with samples of these, and some six weeks ago the editor called the attention of the postmaster-general to their character, which fact may have had its part in bringing about the present exposure. It is the easiest thing in the world to incorporate in some states a high-sounding, degree-giving, fraudulent concern, and these recent and earlier developments indicate that such foundations meet a felt want of a certain sort. There is scarcely any more evident fact than that quite a large proportion of mankind have an everlasting urgent hankering after handles or tail-pieces to their names, which shows itself all the way from the illicit adoption of the honorable title of Doctor down to the marriage of silly heiresses with impecunious fortune-hunting dukes, etc. Dr. Pangloss, LL. D., A. S. S., is very much to the fore, and his last degree is the fitting honorary one which should be given the patrons of these policy shops. It is a fortunate thing for the country at large that where state laws fail we have, in the postal statutes free from all constitutional limitations, a means of dealing justice in Federal courts to these impostors.

THE PHYSICAL EXAMINATION OF SCHOOL-TEACHERS.

A year ago the Chicago Board of Education, on the instigation of Dr. W. S. Christopher, a member of the Board at the time, adopted the plan of requiring all candidates for entrance to the Chicago Normal School, maintained by that Board, to pass a physical examination at the hands of a board of medical examiners, appointed and paid by the Board. As a result of one year's trial it is asserted by those who are in a position to know, that the physical improvement among the candidates is noticeable and fully bears out the claims made by those who proposed the innovation. As one of the examining physicians puts it: "It shows that in one short year the effect of the plan has been to arouse the young women to the necessity of care for their health. Knowing that this examination was coming, these girls have taken care of themselves. They have had soup for lunch instead of a few cookies. They have not dieted, as they used to, on slate pencils and pickles." The advisability of employing as teachers only those who are in good physical condition is certainly recognized by all physicians. And this year the Board has extended the examination to graduates of the Normal School, and all others applying for certificates to teach in the Chicago schools. The teacher who is suffering, weak or afflicted with any bodily ailment that lowers the tone of the system will become nervous, peevish, irritable and impatient, in spite of all efforts to avoid it, which is the very opposite to the condition one should be in who has under her control the young and impressionable. In providing for the qualifications of women who have to assume the important work of molding the plastic minds of children, small attention has been given to the physical condition, and yet it is much more important than many of the literary qualifications that are required, especially when we consider that patience, forbearance, leniency and a cheerful disposition are so essential in a schoolroom. But the application of a physical test to all young women who desire to teach, granting certificates only to those who can pass such a test, would be a blessing to them also. Many a woman has been made a permanent physical wreck in the schoolroom, usually because physical defects existed when she entered. For the sake of the future of both the teacher and of the children let the first qualification required of the former be a healthy body.

EXAMINATION IN MEDICINE IN NEW YORK.

A few weeks ago the Regents of the University of the State of New York, who have the supervision and control of medical qualifications in that State, adopted a rule that students who had passed the entrance examinations and completed two courses of not less than nine months, each could pass their final examination in chemistry, anatomy, physiology and hygiene. Having passed this they would be given a certificate to apply on their final examination as regards these branches. This would enable them to devote themselves more fully to the other branches of their medical course for their last two years and thus better fit themselves for their final examination. This was considered to afford a decided advantage to the New York medical schools, and while one or two details were criticised, it was welcomed as a very acceptable change. The Regents, however, appear to have a doubt whether in this preliminary pass examination there might not be a possibility of lowering the grade of medical education, and, according to the press reports, they have, by a recent ruling, made it impossible for anyone under 21 to be admitted to the preliminary examination. This, it is said, will rule out one-half of the students otherwise eligible, and, according to the reports, the medical colleges in the State are about to use all their influence for the abrogation of the rule. We were not before aware of this large proportion of immaturity in the New York undergraduates, and the rule seems on the whole a very judicious one. While there are exceptions, the very youthful medical student has had too little time to acquire the preliminary education or the mental maturity to fit him for serious professional studies, and it would be well for the profession if such a rule or one closely corresponding to that made by the Regents were generally adopted. As we understand it, they have only made 21 the limit for students finishing their second year, which ought not to be a very serious hardship. Medical students in their "teens" are too often, if not as a rule, too precocious for their own good and that of others, and we trust, therefore, that the ruling will not be changed. If New York students are so largely still under age, it will do them little harm to wait.

Medical News.

ALABAMA.

Dr. John W. Barclay, Birmingham, was seriously injured in a runaway a short time ago. His arm was broken and he sustained severe contusions.

The Alabama Brice Insane Hospital, Tuscaloosa, now contains 1670 patients, 1209 of whom are white, and 461 colored. The colored patients are to be removed in a short time to the new hospital at Mount Vernon.

Want Their Own Physician.—There is prospect of trouble at the Warner coal mines of the Republic Iron and Steel Company because the men desire a physician agreeable to them, and the company is so far non-committal in this particular.

The New Hillman Hospital, Birmingham, is to be located at 20th street and Avenue F. The contract for the erection of the building was let on August 26. It is to be four stories in height, and the contract calls for its completion within four months.

CALIFORNIA.

Dr. H. Isaac Jones, San Francisco, will be absent in Europe for one year.

Dr. John G. Berneike has been elected health officer of Santa Ana, vice George W. Minter, resigned.

Dr. Curtis H. Castle, Merced, has sold his practice and will take a tour in Central America, after which he expects to practice in San Francisco.

Apply for Licenses.—Since the new law went into effect, 6725 applications to practice have been received by the State Board of Medical Examiners, only about one-third of which were made by residents of the state.

The Berkley Hospital Association has secured plans and a site, and is now ready to begin construction. The building is to cost $15,000, and will have an initial capacity of 20 beds. It is planned eventually to enlarge the building so that it will accommodate 100 patients.

DISTRICT OF COLUMBIA.

Dr. Austin M. Curtis, surgeon-in-chief of the Freedmen's Hospital, Washington, has tendered his resignation.

New Licenses.—Of the 27 applicants for license who were examined in July, all but three passed the examination of the Board of Medical Supervisors.

Casualty Hospital Report.—The annual report of this hospital shows that 173 cases were treated in its wards, 933 operations performed, and 1276 emergency cases cared for. The directors decided to equip a new room for the reception of emergency cases.

Natural Healer Fined.—A 30-year-old banana dealer was fined $50 in Washington, August 17, for practicing medicine without a license. He admitted that he was not a graduate, but claimed immunity because he charged no fee for diagnosis, and only took pay for the medicines furnished.

GEORGIA.

Dr. Olin H. Weaver, Macon, has been appointed major and surgeon in the National Guard, and assigned to the Second Georgia Infantry.

The Atlanta Society of Medicine, through its attorneys, has filed an answer to the $10,000 damage suit brought against it by Dr. Bryan. The answer sets forth that the committee of the Society "did undertake in good faith and without malice to ascertain who were illegal practitioners, and to that end instituted a diligent search through the recognized city directories of Atlanta, through investigating signs and names upon office doors, advertisements and the like, to ascertain who were holding themselves out as practicing medicine, and when a list of the persons so holding themselves out had been obtained, the committee then, in good faith and without malice, compared these names with the names of those physicians who were registered according to law."

ILLINOIS.

Fire Loss.—Dr. E. P. Sloan, Danvers, lost his house by fire, August 20. The loss was $600, fully covered by insurance.

Evanston Hospital.—The new addition to this hospital will be completed in October. It includes a ward each for men, women and children. nurses' quarters, servants' rooms and a ward for special cases.

Lightning Interferes with Operation.—During an operation for an abdominal tumor at the Sherman Hospital, Elgin, the operator, assistants and nurses were surrounded by falling glass. Lightning struck the cupola of the building and shattered the skylight over the operating-room.

Hospital Employes' Pay Raised.—The directors of the Illinois Eastern Hospital for the Insane have adopted a scale of wages which will affect 500 employes. The initial salary for male attendants will be $25 instead of $18; for female attendants, $18 instead of $14; and attendants in charge of wards, $42 instead of $35.

Sherman Hospital Advisory Board Resigns.—The Advisory Committee of Physicans to Sherman Hospital, Elgin, composed of Drs. James A. Rutledge, William C. Bridge and Leonard S. Taylor, has resigned. This is another step in the conflict which has been precipitated by the efforts of the Elgin Woman's Club to dominate the medical staff and conduct the hospital after methods of its own devising.

Personal.—Dr. George E. Clement, Springfield, formerly assistant to Dr. George N. Kreider, has gone to Peru, Ind., as surgeon of the Wabash Hospital in that city.——Dr. P. H. McRaven has resigned as superintendent of the Cobden Hospital.——Dr. Leonard A. Robison and family, Canton, have returned from an extended eastern trip.——Dr. Frank Anthony, Sterling, is now securely convalescent and expects to resume practice this week.——Drs. J. H. Finch and Jess A. Fullenwider, Champaign, returned from an eastern trip, August 20.——Dr. Roy B. Roberts, Brooklyn, has moved to Augusta.——Dr. Henry W. Vanderhoof, Wheaton, has been appointed physician to the Du Page County Farm.——Dr. Thomas W. Keys, Leroy, returned from a trip to England, August 19.

Chicago.

The Graduate Nurses' Association of the State of Illinois, Chicago, was incorporated, August 22, by Harriett A. Fulmer, Emilie Lutz and Marie L. Cuthbertson.

Unlicensed Practitioner Indicted.—The State Board of Health has brought action against a chiropodist and magnetic healer of West Madison street, charging her with practicing medicine without a license.

Chicago Death Rate.—For the week ended August 24, the annual death rate was 15.57 per 1000. Of the 526 deaths reported 146 were from acute intestinal disease; 43 from tuberculosis, and 32 each from pneumonia and violence.

"Christian Science" vs. Typhoid.—On August 26 a young girl died from typhoid fever. She had been under the care of a regular practitioner and had improved. The doctor was accordingly dismissed and a "christian scientist" called in. The child grew worse and died while the "scientist" was reading to her. The physician who had been dismissed very properly refused to issue a death certificate and the case is now in the coroner's hands.

No New Smallpox Cases.—For the first time since January 1 *no new* case of smallpox was discovered last week and there are but two cases remaining in the Isolation Hospital, four having been discharged during the week. Notwithstanding the alarm concerning scarlet fever and diphtheria in certain quarters there are no new infected areas and the preventive measures being enforced are relied on to restrict further spread in the localities heretofore reported.

Personal.—Dr. and Mrs. C. St. Clair Drake left for a trip to eastern resorts, August 20.——Dr. W. X. Sudduth has returned from his summer vacation.——Health Commissioner Dr. Arthur R. Reynolds reached Chicago, from Europe, August 27.——Dr. Hugh Upton had several ribs fractured and was injured internally in a runaway accident at San Bernardino, Cal., August 25.——Dr. George Morgenthau is spending his vacation in Colorado and will return September 9.

Food Values.—It is announced that professors of Rush Medical College are planning a series of experiments to determine the effects of different foods upon the mental power of individuals. They will experiment for the most part upon students of the Chicago Hospital School, 5401 Drexel avenue, which has been recently affiliated with Rush. The students of this school, which has a large number of defective children, will be divided into classes and restricted to a particular diet for a certain length of time, until the effects can be noted.

Typhoid Investigation.—At the close of last week the investigation of 67 out of the 123 fatal cases of typhoid fever reported to the Bureau of Vital Statistics between July 1 and August 24 had been completed by the volunteer medical inspectors under the direction of Dr. John C. Neely, assistant chief medical inspector. Of these 67 cases 11 were found to have been undoubtedly contracted outside of the city, and 2 others were doubtful. This proportion agrees very closely with the results of previous investigations, to-wit, that about 18 per cent. of the fatal cases of typhoid in Chicago are contracted elsewhere and are not due to local causes. Among the remaining 54 deaths referred to typhoid fever 9 were clearly caused by other diseases and, in the opinion of the investigators, 6 others were doubtful. Including these 6, however, as among the typhoid deaths the investigators attribute the following as causes of the disease: "bathing in the lake," 2; "eating raw vegetables," 2; "drinking untreated hydrant water," 37; and for the remaining four out of the total 45 cases no cause is assigned. Dr. Neely says: "In this investigation particular attention was paid to the milk and ice supply. Three different milk dealers each furnished milk to two of the homes where deaths occurred, and one other to three of the homes. Ice was furnished to three families by two firms and to two families by another firm. So far as can be learned no connection can be established between the homes supplied with milk and ice by these firms."

Menace From Smallpox.—The July issue of the Bulletin of the Department of Health reproduces Dr. Spalding's article on smallpox which appeared in The Journal of August 3, and urges preventive measures. An increase of more than 87 per cent. in the number of smallpox cases—from 2566 to 4816—was reported to the surgeon general of the United States Marine Hospital Service, between June 28, 1901, and July 26, 1901, over the number reported during the corresponding period of 1900. Since the first of the year and up to the end of July there have been a total of 35,526 cases reported, as against a total of 15,132 cases during the corresponding period last year—an increase of 134 per cent. in this, the fourth year of an actual smallpox epidemic. Dr. Spalding's paper should set at rest any doubt as to the nature of the disease. As he points out, mild and irregular as the majority of the cases are, they still are capable of conveying to the unvaccinated typical, confluent and hemorrhagic forms of smallpox. That the disease thus far has been mild in character and the death-rate phenomenally low is no guarantee that it will so continue. In 1898 scarlet fever was endemic throughout all parts of Chicago, but the type of the disease was so mild that the scarlatina mortality of that year formed but 0.29 per cent. of the total mortality, while, for the forty-eight years, 1851-1898, inclusive, the proportion was 3.11 per cent. Towards the close of the year the type of the disease suddenly changed to one of great malignity, and during the following year, 1899, there were 533 deaths from scarlet fever, or 2.08 per cent. of the total mortality as against the 67 deaths and 0.29 per cent. of the total mortality of 1898. Epidemiology does not yet explain the causes of these changes in type; it only recognizes the fact of their occurrence. Such a change seems now impending as to smallpox. The death-rate in July, 1900, was 1.6 per cent.; during July, 1901. it has been 2.7 per cent.—an increase of nearly 69 per cent. The very mildness of the cases and the low mortality rate constitute a serious menace which should not be overlooked by the sanitarian and health authority. This menace lies in the fact that thousands of undetected cases have spread the contagion in unsuspected ways and places; that, in consequence, no disinfection or other restrictive measures have been employed; and that, therefore, there is every probability of outbreaks from undiscoverable sources in the future. The only and sufficient safeguard against this hidden danger is general vaccination. As has been before said in the Department Bulletins: "No degree of personal cleanliness or of municipal sanitation will protect the susceptible against contracting smallpox if exposed to its contagion. The one certain and only safeguard, tested and proven by the experience of a century, is effective vaccination."

INDIANA.

Dr. William Metz, physician to the Wabash Railway Employes' Hospital, Peru, has been transferred to the hospital at Ashley, Ill.

Elkhart has another case of smallpox with eleven known to have been exposed to the disease at that place, and an unknown number at New Carlisle, at Three Rivers, Mich., and on trains.

The Work House Hospital.—The new hospital at the Marion County Work House, which has been erected at a cost of about $25,000, was opened August 12. The male department will accommodate 8, and the female department, 5 patients.

Mortality in Indiana.—The monthly reports to the State Board of Health show that there were 3162 deaths in the state in July, equivalent to an annual death-rate of 14.8 per 1000. For the corresponding month of 1900 the number of deaths was 2255, a rate of 10.4 per 1000. The number of deaths under one year of age was 698, or 22.0 per cent. of the total number. From one to five inclusive, there were 307 deaths, which is 10.1 per cent. of the total, and of those who were 65 and over, there were 680 deaths, or 22.3 per cent. of the total. The urban deaths numbered 1259—an annual rate of 17.5 per 1000. The rural deaths numbered 1903, a rate of 13.4. Important causes of death were—tuberculosis, 382; typhoid fever, 77; diphtheria, 14; scarlet fever, 5; pneumonia, 53; diarrheal diseases under five years of age, 454; measles, 11; whooping cough, 15. Of the diarrheal diseases 105 were from dysentery.

IOWA.

Dr. James C. Davies, Emmetsburg, has sold his residence and practice to Dr. Horace W. Burnard of Chicago.

New Practitioners.—The State Board of Medical Examiners granted certificates, on August 16, to 64 of the applicants recently examined.

Neglect to Report Smallpox.—City Physician Nicholas J. Schlitz of Des Moines has filed charges with the State Board of Health that Dr. Frank O. Broady had neglected to report to the city board of health two or three cases of smallpox, and has asked that his certificate to practice be revoked. Dr. Broady insists that the symptoms of smallpox were wanting in these cases.

Osteopathic Litigation.—The S. S. Still college of osteopathy of Des Moines has filed in the federal court for the eastern district of Missouri a suit against an organization known as the Associated Colleges of Osteopathy, composed of the American School of Osteopathy at Kirksville, Mo., Bolle's Institute of Osteopathy of Colorado, Boston Institute of Osteopathy of Massachusetts, Northern Institute of Osteopathy of Minnesota, the Philadelphia School of Osteopathy of Pennsylvania and the Southern School of Osteopathy of Kentucky, demanding reinstatement in the association and $5,000 from each of the defendants, who, it claims, at the annual meeting at Kirksville, on July 5, illegally ousted it from membership.

KANSAS.

Registration.—Up to the first of August about 2000 of the estimated 3000 physicians of Kansas had registered. The time for registration of physicians with diplomas expires September 1.

From the Far East.—A Chinese physician of Leavenworth has presented for the inspection of the State Board of Medical Examiners a Chinese diploma, and demands a certificate to practice. Atchison is to have a Japanese physician, a graduate of Illinois Medical College.

The Department of Medicine of the University of Kansas, at Lawrence, has been admitted to membership in the Association of American Medical Colleges, and its course has been approved by the Illinois State Board of Health. The curriculum includes the studies of the first two years at medical colleges and the certificate of the university will admit the student to the third year in any medical college in the Association.

MARYLAND.

Change in Computing Death Rate.—The Health Department has recently made an important change in the method of computing the death-rate. Hereafter the calculations will be based on an estimated population of 518,000, viz., 439,000 white, and 79,000 colored, instead of 541,000. The annual death-rate on this basis for the week ended August 17, was 21.88, and for the following week, 20.38.

Personal.—Dr. W. H. Smith of the University of Maryland staff is at Queenstown.—Dr. Edward A. Schutz has returned from a trip to the Holy Land and Germany.—Dr. John Turner has returned from Nova Scotia.—Assistant Health Commissioner Jones has returned from New York.—Dr. William Lee Howard is cruising in his new yacht along the shores of the Azores.—Dr. Robert P. Winterode, pathologist at the Maryland Hospital for the Insane, Spring Grove, is ill at the Johns Hopkins Hospital with typhoid fever.—Dr. Joseph C. A. Wunder is at St. Joseph's Hospital with appendicitis.—Dr. T. J. Ward has returned from the Pacific Coast.—Dr. Ferdinand Groshans has gone to Buffalo.—Dr. A. Douglas McConachie left for Buffalo and Canada.—Dr. T. L. Richardson has gone to Buffalo and Canada.—Dr. James Bosley, health commissioner, is at Cape May.—Dr. J. W. C. Cuddy is at Atlantic City and will go to the Buffalo Exposition before returning.

Typhoid in Baltimore.—Of the 36 cities of the United States with 100,000 or more population Baltimore ranks thirty-first in point of health, according to census figures. The health officials attribute much of the typhoid fever to the unfiltered water and call for a filtration plant as an essential to health. The water board on the other hand says that it is unnecessary; that every case of typhoid is closely watched by the inspectors, the drainage of the house changed if necessary and every precaution taken to prevent the drainage from going into the lake. To show that the water is not polluted the following analysis by the chemists is published: Color, yellowish, turbid; odor, none; reaction, neutral; total residue at 230 F., 98; volatile residue, 28; ignited residue, 70; amount of chlorin, 2.74; amount of nitrogen as free ammonia, .024; amount of nitrogen as albumin and ammonia, .128; amount of nitrogen as nitrates, .96; character of water, good; nitrates, none. The Health Department will have elaborate examinations of the water made.

MINNESOTA.

Dr. Frank E. Bissell, Litchfield, succeeds Dr. O. S. Pine as surgeon at the Soldiers' Home, September 1.

St. Paul Hospitals.—St. Paul now has four well-equipped hospitals. A fifth, the Norwegian Hospital, will be opened October 1, and within a year a German Lutheran Hospital and a hospital built and operated by prominent physicians for private patients only, will be ready to receive patients.

Less Smallpox.—Smallpox in the state has decreased about 40 per cent. The number of new cases reported since August 1 is 126, against 239 for the two previous weeks. But one death occurred. The largest number of cases reported was in Washington County. Oneka township, where the State Board of Health has intervened to enforce quarantine, has 24 out of a total of 26 cases; Stillwater has the other two.

NEW JERSEY.

Newark School Inspection.—The Newark Board of Health and Board of Education, at a joint meeting, have decided to employ 12 physicians as public school inspectors at a salary of about $250, to make daily inspections of the schools and school children of the city.

Trenton Hospital Scandal.—An investigation into the charge of murder of a patient at the State Hospital for the Insane by attendants, and of inhuman and brutal treatment of other patients by attendants, is being conducted under the personal supervision of Governor Voorhees.

Medical Library in Trenton.—In the interests of the medical department which the physicians of Trenton desire to add to the public library, Dr. Charles Perry Fisher, librarian of the College of Physicians, Philadelphia, delivered a lecture to the medical profession of Trenton, August 22.

Doctor's Bill a Preferred Claim.—Whether a physician's bill should be a preferred claim against an estate has been decided in Camden by Judge Armstrong when he made an order entering Dr. E. L. B. Godfrey's bill of $349 against the estate of Caroline Cooper as one to be preferred above others in the settlement of the estate.

NEW YORK.

The remains of Dr. James Stoughton, U. S. Navy, who was drowned in Chinese waters last year, were interred, August 20, at the Albany Rural Cemetery.

The new hospital at Fort Ontario, Oswego, was accepted by Major Martin, of the army, August 15, and the keys turned over to the hospital steward, who occupies the second floor as his residence.

Smallpox on Excursion Boat.—The discovery of a case of smallpox on an excursion boat between Oswego and Alexandria Bay, August 25, created a panic on board. The patient on his return to Oswego was isolated at the Oswego Hospital.

Two State Societies to Meet.—The New York State Medical Association will meet at the Academy of Medicine, New York City, under the presidency of Dr. John A. Wyeth, October 21 to 24, inclusive. The Medical Society of the State of New York will convene in New York City, the week previous.

Buffalo.

The medical department of the University of Buffalo will begin the session of 1901-02, Monday, September 30.

Epidemic Typhoid.—The Niagara Falls *Gazette* makes the statement that typhoid fever is epidemic in that city. It is attributed to contamination of water from Buffalo sewage.

The Emergency Hospital at Eagle and Pine streets is rapidly nearing completion and will be ready for occupancy October 1. The new building will contain accommodation for 100 patients.

The Fresh Air Mission has already sent 715 children to Cradle Beach this summer for a fortnight, and another party of 70 or 80 has again been sent. The season will close one week earlier than usual because of lack of funds.

Col. Charles R. Greenleaf, assistant surgeon-general, will represent the Superior Board of Health of the Philippine Islands at the annual meeting of the American Public Health Association to be held in Buffalo, September 16 to 20.

Chloroform Death.—A case of death from chloroform anesthesia has occurred at the Buffalo General Hospital. The patient, a man 34 years old, went to the hospital for the purpose of having a slight growth removed from his arm, and died under narcosis.

Gowanda Quarantine Raised.—Health Commissioner Wende has returned from Gowanda after raising the quarantine against smallpox with which some of the Polish factory workers were afflicted. There were seven cases, but every one was vaccinated and the danger is now past.

New York City.

Gift to French Hospital.—Robert Lebaudy, of France, has subscribed $10,000 to the building fund for the hospital the French Benevolent Association is to build in West Thirty-fourth street.

Abatement of Nuisance.—The health authorities of New York City have informed the New York Central Railway that the nuisance found to exist in the tunnel running out from the Grand Central Station must be abated or drastic action would be taken. The principal sources of complaint are insufficient lighting and ventilating facilities in portions of the tunnel.

Sick Children's Mission.—Sick children from the tenements of New York to the number of 2500 have already received medical service from the Sick Children's Mission of the Children's Aid Society since the opening of the season, June 15. This compares favorably with 1157 such patients attended by the same organization during the entire season last year. To fully 20 per cent. of the 2500 cases aided by the mission nourishing foods as well as medicines have been supplied.

Oil Treatment of Mosquitoes.—Dr. Doty has completed the work of treating the chain of stagnant ponds near the quarantine station on Staten Island with oil for mosquitoes, and is highly pleased with the result so far achieved. Millions of dead mosquitoes were found in the pond treated with oil. Many other millions which were just in a state of becoming mosquitoes were also found dead. The work has been successful past expectations.

OHIO.

Card Index of Deaths.—The sanitary policeman of Youngstown is making a card index of all deaths in the city for the last ten years—about 7000 in all.

Dr. Michael A. Albi, Cleveland, who was compelled to sue the parents of a patient, who died after an operation for appendicitis for the amount of his bill, has been awarded a judgment of $75.

Spitting Ordinance to be Enforced.—Dr. Clark W. Davis, Health Officer of Cincinnati, announces that he is about to start a campaign against the violators of the ordinance prohibiting spitting in street cars and public conveyances.

Charity Physicians of Columbus.—The director and superintendent of the Health Department of Columbus have awarded the contracts for poor physicians in the various wards of the city to the nineteen lowest bidders, whose bids vary from $48 to $440.

Typhoid at Hiram.—Secretary Probst, of the State Board of Health, has returned to Columbus, from Hiram, where he investigated an epidemic of typhoid fever. There were 40 cases. The epidemic is attributed to the water from the well on the Hiram college campus.

Personal.—Dr. H. C. Rutter, Gallipolis, has gone to Columbus, where he will resume practice.——Dr. William Pritchard, Cincinnati, has been appointed second assistant physician at the Columbus State Hospital.——Dr. Ernest Scott, Columbus, is going abroad for study.——Dr. Allan Brankamp, Cincinnati, is expected to return from Europe, September 15.——Dr. George A. Gorsuch, and Dr. and Mrs. C. Melvin Harpster, Toledo, sailed for Europe, August 24, on the *Maasdam*.——Dr. George W. Moorehouse succeeded James S. Knowles as superintendent of the Lakeside Hospital, Cleveland, August 17.

TENNESSEE.

Dr. James A. Albright, Nashville, secretary of the State Board of Health, has gone to his old home in North Carolina on a visit and will go to Washington before his return.

No Spitting in Nashville.—The inspectors of the Nashville Board of Health have been instructed by Dr. Larkin Smith, City Health Officer, to strictly enforce the law against expectoration in public conveyances and public buildings, and to arrest offenders.

Personal.—Dr. James F. Roper, Harris, has sold his practice to Dr. R. V. Dukes, of Laurel, Miss., and will move to Union City.——The office of city health officer of Chattanooga expired by limitation, August 19.——Dr. William H. Poindexter, Bells, has been elected a member of the local board of health.

School Children Must Be Vaccinated.—The Board of Health of Memphis, on August 15, adopted a resolution declaring compulsory vaccination of all children in the city a prerequisite to their attending the various schools, public and private. Dr. Hasse, secretary of the board, stated in explanation that certificates previously given will be satisfactory and that no certificate will be demanded where a satisfactory vaccination scar can be shown.

WASHINGTON.

Scarlet fever, in mild form, is increasing at Walla Walla. In the last five days of July, 11 new cases were reported.

Dr. George W. Libby, Spokane, a member of the Board of Plumbing Examiners, has resigned in favor of a representative of the journeymen plumbers.

Changes of Location.—Dr. Francis J. Ledbrook, of Lakefield, Minn., has located in Moscow.——Dr. Alexander Smith, Oakesdale, has moved to Vineland.

Walla Walla Hospital.—During the eighteen months since the opening of this institution, 371 cases have been treated, 201 of which were surgical and 170 medical. There have been 84 gynecological cases and 33 case of typhoid fever.

WISCONSIN.

Typhoid in Baraboo.—It is reported that more than 2 per cent. of the population of this town are ill with typhoid fever.

New Licensees.—Of the applicants who took the recent examination by the State Board of Medical Examiners, 28 passed and have received licenses to practice in Wisconsin.

Unregistered.—It is reported that 125 of the 400 physicians of Milwaukee have failed to comply with the law requiring them to file their certificates with the county clerk before March 30, 1900.

Personal.—Dr. Edgar J. Orvis, Oakfield, who disappeared August 3, has been heard from. He writes Dr. J. W. Burns from New York intimating that he would never return.——Dr. Anton B. Opicka, Wonewoc, has been arrested, charged with practicing medicine without a license.——Dr. Frederick Deutschberger, Milwaukee, possessor of many certificates, but no diploma, plead guilty of practicing without a license and was fined $50 and costs.——Dr. Oscar E. Lademann, Milwaukee, has returned from a 3-years' course of study in Berlin and Vienna.

Smallpox Epidemic Threatened.—Dr. Uranus O. B. Wingate, Milwaukee, secretary of the State Board of Health, declared on August 20 that Wisconsin and all states of the middle West would be swept by a scourge of malignant smallpox unless prompt and early action were taken against the disease. He proposes to locate the disease by getting a list of the infected camps. He will then ask all lumber contractors to make vaccination a condition to employment among the men. Detention hospitals will be erected and instead of allowing those who have the disease to go at will among the settlers, they will be confined until cured. As the matter now stands, as soon as a man is known to have smallpox he is discharged, and immediately goes out of the woods into the settlements. Then, in order to get to the very hiding places of the disease, the infected camps must be destroyed, and further damage from that quarter prevented.

GENERAL.

Honolulu News.—Queen's Hospital is to receive an appropriation from the legislature of $1666 monthly.——The leper examining board, as reconstituted, consists of Drs. Sloggett, Cooper, Moore, Meyers, Sinclair and McDonald.

Mosquito-Infected Nurse Dies.—Miss Clara Maas, a nurse at Havana, formerly of New Jersey, allowed herself to be bitten by two infected mosquitoes and died, August 24, seven days afterwards of yellow fever. She desired to become immune. This gives three deaths out of six experimental cases during this month at Havana.

Mental Healers Give Bonds.—Helen Wilmans, 70 years old, founder of a "Mental Science Association," with her husband and son-in-law, were arraigned in the United States Court at Jacksonville, Fla., and gave bonds in the sum of $5000 each. The postoffice authorities state that they have sufficient evidence to convict them.

Medico-Military Journal.—The Association of Military Surgeons of the United States is about to publish a journal instead of issuing an annual volume of transactions. The contracts for its publication have already been made, and the first number of the journal will appear shortly. The editor-in-charge is Captain James E. Pilcher, assistant surgeon, U. S. Army, retired, under the supervision of a governing board.

Dr. A. P. Ohlmacher has been appointed professor of pathology in the Northwestern University Medical School (Chicago Medical College). Dr. Ohlmacher is director of the pathological laboratory of the Ohio Hospital for Epileptics at Gallipolis, where he has done excellent practical work, particularly on the morbid anatomy of epilepsy. Previous to going to Gallipolis he was professor of comparative anatomy and embryology at the College of Physicians and Surgeons, Chicago; later professor of pathology in the Chicago Policlinic, and from 1894 to 1898 professor of pathology in the Cleveland College of Physicians and Surgeons. He will retain his position at Gallipolis for the present.

Braithwaite's Retrospect Discontinued.—The 73d volume of *Braithwaite's Retrospect*, just received, contains the announcement that this historic semi-annual journal is to be discontinued, that the last volume has been issued. For over sixty years *Braithwaite's Retrospect* has been a mirror of all that was new, of value in medicine, and was the precursor of the modern year-book. As the editor says in the announcement of the discontinuance, medical journals now provide regularly, abstracts and summaries of medical literature from all parts, with the consequence that they each contain a retrospect of that which is new in medicine which was formerly only to be had in more special publications. While the *Retrospect* has, in some respects, outlived its usefulness, its career has been one in which its founder was justly proud, and there will be a pang of regret among many of the older members of the profession, both in this country and in England, at the thought that it will appear no more.

CANADA.

Many cases of smallpox are reported from a small village near the capital, Ottawa. In an area of five miles, there are some 35 cases. Ten families are suffering from the infection up to the present date.

The McGill medical faculty has postponed the sessional opening this year until October 1, instead of September 13, as formerly. This is on account of the many alterations now proceeding. Every effort is being put forth to have the library, the faculty rooms and the new laboratories completed before the expected visit of the Duke of York.

Dr. Thomas Page, Brockville, Ont., was killed at Cornwall on the night of the 21st inst., by being run over by a train. While stepping on the train he missed his footing and fell under the wheels. One leg was cut off, while the other was badly crushed. He was removed to the Cornwall General Hospital, where he died the following morning.

Personals.—Dr. Joseph Prendergast, Chicago, is visiting friends in Toronto.——Dr. Aristide Blais, Berthier, who returned a few weeks ago from two years' study in Paris, has been spending a few days in Montreal, on his way to Alberta, N. W. T., where he intends to take up practice.——Dr. Aldege Ethier, formerly house physician at the Notre Dame Hospital, Montreal, has returned from Glasgow, where he went some months ago. He will spend some days in Montreal, and then go to Paris, Ont., to take a position in St. Michael's Hospital.

Montreal General Hospital.—At the quarterly meeting of the Board of Governors held during the week, Dr. F. J. Shepherd opposed the scheme for charging 5 to 10 cents for medicine to outdoor patients. Since the charge was instituted, there has been a great falling off in the outdoor patients. At the next meeting Dr. Shepherd will move to have the charge removed. During the past quarter 783 patients were treated to a conclusion. Of these 56 died, 25 of them within three days of admission. The charge for medicine made during June and July produced $186.20. The number of patients at the outdoor department during these two months was 4220, as against 6081 in 1900.

The Health of Ontario.—The nineteenth annual report of the provincial Board of Health of Ontario for the year 1900 has just been issued. In addition to the regular report of the secretary, it contains special reports on the outbreaks of disease, etc. The laboratory work during the year shows that 1669 specimens were examined as follows: Sputum, in cases suspected of tuberculosis, 703; exudate, in cases suspected of diphtheria, 526; blood, in cases suspected of typhoid fever, 221; water for bacteriologic examination, 194, and water for chemical examination, 33. Of 480 tuberculosis specimens sent, 170 showed the bacilli of tuberculosis, 79 being from males and 91 from females, the great preponderance of positive cases being between the ages of 20 and 30 years. Of 526 cases suspected of diphtheria, 247 showed the bacilli. In 221 specimens examined for typhoid, 54 gave a positive result.

"Christian Scientist" Arrested.—The father of a boy who recently died in Toronto from diphtheria while under "silent treatment" has been placed under arrest pending an investigation. As an evidence of a strong growing sentiment against this cult, the verdict returned by the coroner's jury is interesting: "That the said boy came to his death on Tuesday, August 13, at the home of his parents, from diphtheria, and we find the father of the deceased showed culpable criminal negligence in not providing medical assistance, nursing and comforts, and that ——, the 'christian science' demonstrator, was an accessory after the fact, inasmuch as he undertook to advise and treat a dangerous and contagious disease, which he admitted he was totally ignorant of. The teaching of the sect known as the 'christian scientists,' as brought out in the evidence, is a danger to the community, and the jury would recommend that the law should make it a criminal offense for a demonstrator of this peculiar sect to attend or treat a case which is not being attended by a duly qualified practitioner."

FOREIGN.

Staff Surgeon-General Coler, of the German army, died recently at Berlin.

Tribute to Hansen.—A bust of Dr. G. H. A. Hansen, the discoverer of the leprosy bacillus, was unveiled on August 10, at Bergen, Norway.

French Congress of Urology.—The fifth reunion of the urologists of France and other countries will be held at Paris, October 24 to 26, with Guyon in the chair. Movable kidney is the chief subject appointed for discussion. The general secretary is E. Desnos, 31 rue de Rome, Paris.

Egyptian Medical Congress.—The profession in Egypt is organizing a medical congress to convene at Cairo, December 10 to 14, 1902. It will be under the patronage of the Khedive, and the first great gathering of scientific men in an Oriental country. Cholera, bubonic plague and dysentery will, it is expected, receive due consideration. Dr. Voronoff is secretary-general in charge of the arrangements.

LONDON LETTER.

Complimentary Dinner to Surgeon-General Jameson.

A complimentary dinner has been given to the Director-General, at which Sir William Church, president of the Royal College of Physicians, presided, and which was attended by a large number of the most eminent medical men in London, including Sir William MacCormac, president of the College of Surgeons, Sir Lauder Brunton, Dr. Conan Doyle (the well-known novelist), and Sir Frederic Treves. The chairman said they had met to do honor to one who deserved well of his country and of his profession. He was placed somewhat in the position of having to make bricks without straw. The present war was unique in its difficulties. Never before had so many men left our shores for so great a distance. But he met all the requirements which were placed upon him. Surgeon-General Jameson said in reply that when the army in South Africa was first doubled and then trebled a great strain was placed on his department. Soon invalids began to be received from Africa in thousands. Up to the present 50,000 had been received. Not one of these was transferred to a civil hospital. The reserve of the Corps was first called out; then, they enlisted and trained men as fast as they could. Every man that could be spared was recalled from the Colonies. Then, they tapped the militia and volunteer medical staffs. For a considerable time before the war broke out the Director-General and his staff urged upon the government the necessity of increasing the Medical Corps, but for the most part without avail. The department had sent to Africa 4000 tons of medicine and material, and had mobilized 151 staff and regimental units, 19 bearer companies, 28 field hospitals, 5 stationary hospitals, and 16 general hospitals. They had fitted out in this country 2 hospital ships and 3 hospital trains. At the present time there were 21,000 beds in South Africa, not counting field hospitals. Fault had been found with his department for not having made sufficient sanitary arrangements in the field, and this in face of the fact that the post of sanitary officer had been abolished against the advice of the Department. The officers of the Medical Corps, after superhuman efforts, were exposed to criticism and an inquiry such as had not been applied to any other branch of the army and exposed to blame which others should have borne. The sympathy which had been denied to them by others and which found expression in the presence of those at the dinner would be all the more esteemed and valued. Sir William MacCormac said that it was impossible to say too much in admiration of how Surgeon-General Jameson had met every requirement, and it seemed to him passing strange that the government had allowed him to leave the army without the customary recognition given to all his predecessors and without one word of thanks.

Koch's Paper on the Prevention of Tuberculosis.

Koch's recent view that human and bovine tuberculosis are distinct diseases and that the latter is not a source of danger to man, has been widely criticised in the lay as well as the medical press, and has received no support whatever. At the last council meeting of the Royal Agricultural Society, Lord Spencer, speaking on the report of the veterinary committee to carry out experiments on the subject, expressed the hope that the provisions in force for the prevention of the conveyance of tuberculosis from animals to man would not be relaxed while the matter was still in doubt. The most important criticism of Dr. Koch's arguments which has appeared since the Congress is a letter addressed to the *Lancet*, by Dr. Copeman, of the Local Government Board, who is well known for his experiments on variola and vaccinia. He points out that while Koch says that the animals which "had eaten bacilli of bovine tuberculosis had without exception tuberculous infiltration of the greatly enlarged lymphatic glands of the neck and mesenteric glands and extensive tuberculosis of the lungs and spleen," yet no mention is made of tuberculous lesions of the intestine. This omission is all the more remarkable as Koch, in giving reasons for his conclusion that bovine tuberculosis can not be conveyed to man by ingestion of milk or butter containing "living and virulent bacilli," says that it is only "when the intestine suffers" that a case of tuberculosis can be assumed with certainty to have been "caused by alimenta." It will be remembered that the great rarity with which tuberculosis of the intestine is found in necropsies at children's hospitals in cases of tuberculosis was one of Koch's arguments against the origin of the disease from ingesta. Lord Lister, in replying to Koch at the Congress, pointed out that if primary intestinal tuberculosis were rare in children mesenteric tuberculosis was common, and said that the interpretation seemed to him to be that the bacilli passed through the intestinal mucous membrane without causing any obvious lesion and were arrested in the glands. Unless Koch made an important omission in his paper this is exactly what he claims to have taken place when he fed cattle with bacilli from bovine tuberculosis; yet without any reason he implicitly denies its possibility in man.

Correspondence.

Impressions of the London Tuberculosis Congress and the Black Forest Sanatoria for Consumptives.

WATCH HILL, R. I., Aug. 23, 1901.

To the Editor:—This gathering of medical men was the largest and most complete ever assembled for a special purpose. As I sat on the platform during the opening meeting, when the different nations, through their designated delegates, were introduced, I knew that it had never been my good fortune, in all the medical conventions I have attended, to look upon such a distinguished body of men. When the 2000 members were present they filled completely the body of Queen's Hall, where the general sessions were held. Of this assemblage of men I should judge nearly one-half were from outside of England. America, France and Germany especially had good representations. It was indeed an honor to be a member of it, and to take part in such a Congress.

It would seem that the Londoners purposed to outdo all previous medical gatherings in social features, and I congratulate them on their success. The Englishman is at home and the prince of hosts when dining is the order of the day.

A dinner was given by Sir James Blyth, on Monday, to the Duke of Cambridge, who presided at the opening meeting of the Congress. There were present the Earl of Derby, the Lord Mayor of London, and distinguished members of the nobility, of the foreign and local medical profession, to the number of sixty. There was the "At Home at Apsley House" Tuesday afternoon on the invitation of the Duchess of Wellington, who, with her husband, gracefully received us in that stately mansion filled with the costly rewards and war relics of their ancester, "the Duke." The pleasure of attending the Baron de Rothschild's reception in their princely house, I feel, was also, with the two functions previously named, afforded me through the kind attention of my good friend and host, Dr. C. Theodore Williams. Then there was the general reception of the members and delegates on the opening night in Queen's Hall, Langham Place, by the Presidents of the Council of the Congress and the executive officers, a magnificent affair; on Tuesday evening, the reception at the Mansion House, by the Lord Mayor and Lady Mayoress in all their gorgeous official robes, and on Friday night the grand banquet given to the officers and foreign delegates of the Congress. This was not all, but enough has been mentioned to show how well socially the visitors from abroad were looked after.

THE MUSEUM.

A very important feature of the Congress on Tuberculosis was the Museum designed to illustrate the bacteriology and pathology of tuberculosis. It was a wonderful exposition of the subject and the student was aided by a most admirable catalogue. It was gotten up without regard to expense, and was the finest collection it has been my good fortune to see.

The latest methods of preparation of pathological specimens gave fine illustrations of all the possible manifestations of tuberculosis. Especially attractive were the beautiful series illustrating the localization of tuberculosis in the bronchial and mediastinal glands, in some cases of enormous size. These and other like specimens seemed to show in a striking way the important agency of the glandular system in this disease.

In the bacteriological department were remarkable illustrations, through the cultures on exhibition, of all kinds of tuberculosis. There was the 435th culture (in five tubes) of Koch's original discovery of the bacillus tuberculosis, first isolated by him on Aug. 15, 1881. These cultures had been carried down through these twenty years and kept continually growing from the original seed. There were three very interesting test-tube cultures, first showing the normal state of the germ for comparison, second a sub-culture made after exposure to liquid air for 42 days without contact, third a sub-culture after similar exposure with contact—all showing that the bacillus grows as vigorously as ever after exposure for 42 days to 186 degrees F. below zero.

THE CONGRESS A SUCCESS, YET DISAPPOINTING.

As a means of the education of medical men, as an effort preliminary to definite conclusions which must be reached at another time, and as an opportunity for earnest workers, in this special field, to get together from nearly all over the world to compare notes and personally learn from each other their different views, the Congress was a marked success. But as to any definite conclusions reached, it was disappointing. The cut-and-dried resolutions proposed and voted on, without any open discussion, at the last general meeting were commonplace compromises, which probably fairly represented the collective knowledge of tuberculosis possessed by the Council proposing them.

EXAGGERATED IMPORTANCE GIVEN TO MINOR THINGS.

Exaggerated importance and much time was given to the "spitting nuisance," the agency of ladies' long dresses in carrying and disseminating the germs, and to the theory of infection generally in preference to any other hygienic means of prevention, which, to my way of thinking, offer more hope for the extermination of tuberculosis than any agency simply preventing infection.

KOCH'S ADDRESS.

To Professor Koch, more than to any other man must be given the credit of capturing the interest of the Congress by the remarkable stand he took as to the non-infectibility of man by bovine tuberculosis. At Sir James Blyth's dinner, on Monday evening, Dr. Williams came to me and said: "Do you know there is a devil of a rumpus brewing about what Koch is going to say in his address to-morrow? They are getting awfully worked up about it and they won't stand it, and he will be called down." It was a memorable meeting at which Koch read his paper. The interest was intense. To look upon that sea of intelligent faces and to note the excitement and the restrained applause, was an experience one has but once in a lifetime. They cheered the presentation of his views, though the great majority doubted his conclusions. But when Lord Lister, who was that day in the chair, called in question the positive statement Koch had made and said, "It is a serious matter if the conclusions be wrong," the applause was the heartiest of any time that day. And when he asked if it was indeed "established beyond a doubt that tuberculosis is always air-borne." I for one, thought he was getting nearer the kernel of the question than had anyone else. Professor Nocard followed and cited instances where veterinary surgeons had become inoculated by accident with animal tuberculosis. Professor Bang of Copenhagen followed and said, "Koch went too far in saying that there was no necessity for taking measures against bovine tuberculosis." And finally, Professor Sims Woodhead, while complimenting Professor Koch, referred to a specimen in the Museum of the Congress which proved that it was possible for human beings to be infected with tuberculous disease from animals.

One is inclined to ask, is this obstinate conservatism a possible cloak for ignorance of the real cause of tuberculosis? It is as difficult for a typical English doctor to change his settled opinion on a medical subject as it would be for the English tradesman to deal in decimal money instead of their more troublesome and inconvenient six-pences, shillings and crowns. Just think of the dilemma into which they are being driven! Here we have Koch fastening upon his tubercle bacillus limitations which will be in opposition to the idea that the germ sufficiently explains the disease. Avian tuberculosis is supposedly different from the bovine variety, and the latter not transmissible to human beings, and human tuberculosis not infective in animals (?). Here we have Brouardel, of Paris, in a splendid all-round address, "knocking out" the idea of heredity (except of a possible susceptibility to tuberculosis), and Knopf and many others showing that a healthy human being is non-infective to the germ; and Williams showing the splendid results of climatic treatment in proportion as the advantages of practical outdoor living are afforded; and James F. Allen, of Natal, South Africa, explaining the immunity from tuberculosis in his section 3000 to 6000 feet above sea level of three different classes of people, namely the Indians, the English and the Zulu tribes, on the ground that their life is essentially, and in fact, a life out of doors. Then, again, comes Harold Coates, of Manchester, and A. Ransome, of Bournemouth, and others also, showing how bad housing, aggregation and deficient lighting and deficient ventilation foster and produce the disease. Where, then, does the germ come in? Does it not all show (Koch's contention especially included), that to get at the prime cause of tuberculosis we must, as I stated in my own address, go back of the germ to some common predisposing cause which will explain the frequent occurrence of this disease in birds and animals as well as in man? My belief is, that that common cause is deficient ventilation; that the air once used is thereafter not only unsuited to sustain life healthfully, but positively injurious until it has been revitalized by practically outdoor conditions: And that the penalty of the air's devitalization is finally tuberculosis. There is an electrical condition of the air, which is not yet fully understood, but upon which its power of vitalizing and sustaining living plants and beings depends. When our education comprehends this fact we will come nearer the prevention of tuberculosis than we have ever been before.

Sanatoria in the Black Forest.

A very interesting part of my sojourn abroad was the visit to the Black Forest in Germany and the inspection of the Sanatoria for consumptives there, after the adjournment of the Congress on Tuberculosis. Hohenhonnef Sanatorium on the right bank of the River Rhine is a beautiful place situated on rising ground say 100 or 200 feet above the river and flanked on three sides with woods through which wind several miles of graded walks. Here the patients lead a lazy life, most of the time reclining in open-air sheds. They live well. Wine at meals is the rule with many, and five meals a day the custom of most. The place seemed rather damp to one used to Colorado dryness and sunshine, but the 90 or more inmates of this Sanatorium seemed to be contented and doing well. Dr. Feige, the assistant physician, was very kind to me. Together we drove to the top of a mountain near by, where, from the ruins of Drachenfels, is obtained a fine view of the Rhine from Cologne to Coblenz.

Wiesbaden, the great watering place of this part of Germany, reached after a pleasant day's steaming up the Rhine, is a lovely spot. This town illustrates what can be made out of such a simple, natural advantage as an ordinary hot saline spring, of which there are many not yet half appreciated in our own country.

Another day's ride to Frankfort and thence to Colberg brings one to the Falkenstein Sanatorium. This Sanatorium differed not much from that at Hohenhonnef, either in its capacity for receiving patients or the prevalent wooded and damp surroundings, and likewise seemed to offer no unique or original form of treatment.

On my return at Colberg, I fell in with Rev. Mr. Oakes, of the Consumptive Home at Denver, who was on a similar investigating mission, and we had a delightful trip together up through the Black Forest. The railway opened out into frequent stretches of fine farm country, extending up the sides of the hills sometimes to the very summit. We arrived at Cologne late at night, and took train again in the early morning for Offenburg, and transferred thence to Beberack Zell. That morning's ride up the valley to Beberack Zell was very delightful, as every turn of the railroad gave a new and pleasant view, among them the castle of Baroness Hirsh (noted for her philanthropy among the Jews), beautifully covering the whole summit of a small, round hill. From Beberack Zell, where our carriage met us, we followed up an 8-foot wide brook some ten miles, until it became about a foot wide, and there found Dr. Walther's (Detweiller's) Sanatorium. The ride up the valley was delightful. We passed thatched Swiss cottages, where the cows occupy the ground floor, the family the second, and the hayloft the roof space. Here little hamlets crowd close upon the narrow roadway, along which every half mile or so is a shrine, perhaps lately contributed to by some devout worshiper with a sprig of oats or a bunch of flowers. Dr. Walther's main house has windows, but they are all taken out this time of year. The transoms are large and the outlook in the right directions to catch the best summer exposure. There is individualization, as there should be, for each patient, but no special crowding of food as there is at some institutions, simply three good meals a day, and graduated exercise by walking according to each one's ability and condition. He scouted at the use of antiseptics, saying soap and water were good enough to clean up a room with after a patient had died in it. We could not help reasoning that if he had the dryness, sunshine and altitude which we get east of the Rocky Mountains, he would have the best place in the world in which to treat consumption. But then, if he had these, he would not have his heavy foliage and grassy hillsides and the nearness to the people he would serve. Of course, devoting his attention to only 45 patients, all he can accommodate at one time, he is very successful.

The next institution we visited was Dr. Hettinger's, farther down in the same valley. It is a compromise between Dr. Walther's and the first two mentioned. But it is a clean, airy, well-lighted and well-cuisined sanatorium, which, because of its similarity in many respects to his own "Home," in Denver, much delighted the esthetic mind of Mr. Oakes. We could not help noticing the double windows, and I learned that sometimes in winter the storms are so severe that these are deemed necessary. I had heard of the double windows generally used by the Swiss, to which Dr. Tucker Wise attributes the frequent occurrence of tuberculosis in that otherwise healthy country.

Well, they are all coming around to the same belief that we physicians in Colorado have been preaching these many years, namely, pure air and an active outdoor life in that climate where it can be had the easiest and most comfortably.

Yours respectfully, CHARLES DENISON, M.D.

Vivisection—A Reply to Dr. Keen.

TOLEDO, OHIO, Aug. 21, 1901.

To the Editor:—I have read the communication of Dr. Keen, published in your issue of August 10, and already applications have been made by members of the medical profession for literature concerning the subject of the controversy—human vivisection.

As the American Humane Association considers this matter one of vital importance, its executive committee has, after amendment and revision, just printed that Review of Dr. Keen's letter upon which he, in his last communication, comments; and in order to do him justice, the Association has added his first letter, which he has called "The Misstatements of Antivivisectionists." These two documents in one pamphlet can be secured gratis by any physician in the United States who will send his professional card to "The Special Committee," Postoffice Box 215, Providence, R. I. For those medical men who carefully read this pamphlet, it would seem to me that Dr. Keen's latest letter will need no reply.

If your space would permit, there could be pointed out in this document some very serious misquotations, leading him to misstatements and comments which ordinarily would be without excuse. I prefer, however, to join with his many friends in speeding Dr. Keen in his journey around the world, and wishing him a pleasant voyage and a safe return; to leave his misconceptions and mistakes to his own sober judgment, and the rectification that time will surely bring.

This Association can have no quarrel with the medical profession. It believes, rather, that in condemning and opposing the use of human beings, chiefly women and children, for experiments dangerous to life and health, it has the sympathy of the great majority of the physicians of the United States.

Nothing can so surely and utterly destroy all confidence in the personnel of the medical profession, and in the security of our hospitals and asylums, as a well-founded impression that every patient, young or old, strong or feeble, high or low, rich or poor, is not absolutely secure in all of his personal rights.

He who, in the pretended interests of science, consciously aids in the destruction of this confidence or security is, in my judgment, little less than an enemy of his race.

Yours most truly, JAMES M. BROWN,
President American Humane Association.

[We shall be glad to see the publication of Dr. Keen's letters in full with the Humane Association's pamphlets. We have no fear of the judgment of any unbiased individual who is fully informed on the subject, and think that any such one who reads Dr. Keen's replies, as well as the publications referred to by our correspondent, will be able to form his own opinion. Knowing as we do the erroneous character of some of the statements in the Humane Association's pamphlet, some of them based on misapprehensions patent to any well-read physician, it seems to us that Dr. Keen's letter can have no reply. If there is an impression abroad that the rights of the hospital and asylum patients are not regarded by the medical profession in this country, it is due to sensation-mongering newspapers and to misstatements, whether wilful or not we do not care to say, of such publications as those that called out Dr. Keen's replies.—EDITOR.]

Book Notices.

LECTURES ON NASAL OBSTRUCTION. By A. Marmaduke Sheild, M.B. (Camb.), F.R.C.S. (Eng.), Surgeon to St. George's Hospital, London. With 1 Colored Plate and 27 Illustrations in the Text. Cloth. Pp. 106. Price, $1.50. Philadelphia: P. Blakiston's Son & Co. 1901.

This little work is intended primarily for the student and general practitioner. The author is conservative in operative treatment, particularly with regard to septal spurs; he prefers, however, the galvanocautery in hypertrophic rhinitis and seldom uses an acid. The origin of nasal polypi is attributed in most instances to irritation of the mucous membrane by a concomitant bone necrosis.

A PRACTICAL TREATISE ON GENITO-URINARY AND VENEREAL DISEASES AND SYPHILIS. By Robert W. Taylor, A.M., M.D., Clinical Professor of Venereal Diseases at the College of Physicians and Surgeons, New York. Second Edition, thoroughly Revised. With 138 Illustrations and 27 Plates in Colors and Monotones. Cloth. Pp. 722. Price, $5.00. New York and Philadelphia: Lea Brothers & Co. 1900.

This is not a mere aggregation, but a discriminating digest of the latest knowledge of the subject and there is no chapter in the work from which the reader may not learn something new. It is a most satisfactory text-book, and is modern in every particular. It is most comprehensive in its scope, sound and practical in its teachings, and we predict for it a wider circulation than the first edition enjoyed, and in time an urgent demand for a third edition.

THE TREATMENT OF FRACTURES. By W. L. Estes, A.M., M.D., Director and Physician and Surgeon-in-Chief of St. Luke's Hospital, South Bethlehem, Pa. Cloth. Pp. 216. Price, $2.00. New York: International Journal of Surgery Co.

This work of 216 pages is a publication in book form of a series of papers by the author which appeared in the *International Journal of Surgery.* No attempt is made to discuss in a complete manner the entire subject of fractures, and much, therefore, which pertains to the pathologic side of the subject has been omitted. The work is essentially one on treatment, and this phase of the question is handled in an eminently practical manner by one who has had a considerable experience in the management of these acute accidents.

The aim of the author has evidently been to the practical rather than to the scientific, and he has limited himself almost entirely to a description of his own methods.

DISEASES OF THE ANUS AND RECTUM. By D. H. Goodsall, F.R.C.S. (Eng.), Senior Surgeon (late house surgeon) to St. Mark's Hospital for Fistula and Other Diseases of the Rectum, and W. Ernest Miles, F.R.C.S. (Eng.), Surgeon (outpatients) to the Gordon Hospital for Diseases of the Rectum. In Two Parts (Illustrated). Part 1. Cloth. Pp. 311. Price, $2.50. London, New York and Bombay: Longmans, Green & Co. 1900.

Part I deals with the anatomy, general diagnosis, abscess, fistula, fissure and hemorrhoids. The subjects are, in general, very well handled. In the treatment of hemorrhoids preference is given to the operation by ligature to the exclusion of all other methods. While this is the best method in the majority of cases, there are other methods which certainly are of use in special cases, and in a work of this character these methods deserve more attention than to be dismissed as useless by a three-line notice. The illustrations, which are quite numerous, are very good, most of them being reproductions of photographs.

With Part II, which is in preparation, the work will be quite complete and worthy of careful reading.

SURGICAL APPLIED ANATOMY. By Sir Frederick Treves, K.C.V.O., C.B., F.R.C.S., Sergeant Surgeon to H. M. the King. New Edition, Revised by the Author. With the Assistance of Arthur Keith, M.D., F.R.C.S., Lecturer on and Senior Demonstrator of Anatomy at the London Hospital. Illustrated with 80 Engravings. Cloth. Pp. 571. Price, $2.00. Philadelphia: Lea Brothers & Co.

This edition has been revised throughout, certain sections have been rewritten and much new matter added; it is well up to date. The usefulness of the work can be questioned by no one; it is a more attractive presentation of the most important facts of anatomy, especially in their practical bearings. It is, therefore, a convenient reference book and a valuable suggester of much information that is not always easily brought out, so to speak, from the dusty pigeon-holes of the memory. Sir Frederick Treves, as one of the first of British surgeons, is especially competent to furnish such a work, and this latest revision will be of value to practitioners as well as students preparing for their examinations. The illustrations, while not very numerous, have been considerably increased in this edition, and are specially serviceable and well selected.

THE DIAGNOSTICS OF INTERNAL MEDICINE. A Clinical Treatise on the Recognized Principles of Medical Diagnosis, Prepared for the Use of Students and Practitioners of Medicine. By Glentworth Reeve Butler, A.M., M.D., Chief of the Second Medical Division, Methodist Episcopal Hospital. With 5 Colored Plates and 246 Illustrations and Charts in the Text. Cloth. Pp. 1059. Price, $6.00. New York: D. Appleton & Co. 1901.

Works on diagnosis are comparatively numerous at the present time, but each new one has its special features of interest and value. The present volume, while less complete in its scope than some, covers the greater portion of the field of internal medicine in a very satisfactory way and undoubtedly will be found by many more acceptable than other works. It is particularly strong in its illustrations; these are generally very well selected to illustrate the text, which itself is clear and readable. The arrangement of the work is also one that will possibly find favor with many readers, especially students and general practitioners, much the larger part being given to the "Evidences of Disease" or general symptomatology and this is followed by a shorter section on special diagnosis, differential and direct. The treatment of the special subjects in this department is less elaborate than in some other works, but the main points appear to be generally well stated. There seems to be an omission in the absence of descriptions of the usual urinary and other tests. While mental disorders are left out, it would not have been amiss to have included some notice of a condition like paresis, which has a more or less definite pathology and is often confused in its early stages with certain other nervous disorders. Syphilis of the nervous system might have also received fuller treatment.

Taking the work as a whole it may be said to meet most of the requirements of a work on the diagnosis of non-surgical diseases and to possess special merits in some particulars, more especially in its first section. It is well worth a place in the physician's library.

UTERINE TUMORS: Their Pathology and Treatment. By W. Roger Williams, Fellow of the Royal College of Surgeons. Cloth. Pp. 359. Price, $3.00 net. New York: William Wood & Co. 1901.

This monograph opens up with a brief description of the development of the uterus and its anatomic relations. Uterine myomata are then considered in an exhaustive manner. The histology of the uterus in relation to its neoplastic pathogeny, the influence of aberrant elements, "rests," developmental irregularities, gross malformations, and the microbic theory are all considered under the etiology of these new growths. The author thinks that suppressed maternity and sterility "are among the most important factors in the genesis of these tumors."

Is it not more probable that the diminished fertility of these patients is due rather to the pathologic state of the uterus superinduced by the presence of the new growths? Nor does his point find support when he attempts to show the hereditary nature of these growths, for he states "myomatous patients come of large families, for those in my list averaged 8.1 members each." Concerning the etiology of carcinoma he disregards entirely the modern tendency to ascribe this to extrinsic or microbic influences, and says the "great relative proneness of the epithelium of the uterine mucosa to take on proliferative cancerous changes is due to the awakening in its constituent cells of potentialities" derived from their parent cells in the genital ridge which are akin to those which furnish the ovigerms. But such an explanation explains nothing, and will not restrain in the least the earnest search for the cause of cancer which must some day be revealed.

In the operative removal of the cancerous uterus, stress is well laid on the necessity of extending the operation to the removal of the para-uterine tissues and the lymph glands, if better permanent results are to be hoped for.

In the production of this volume the author has labored well and earnestly and given to the profession a work of value.

Miscellany.

The Consumptives Picnic Grounds.—The success of the day-resort for consumptives at Berlin has proved so encouraging that three more have been founded, two for men and two for women. They are all in easily accessible groves on the outskirts of the city and are provided with a kitchen, etc., to supply a nourishing lunch at a minimum price. They were organized by the Red Cross Society.

Success of Organized Effort in Lille.—The local medical society of Lille, France, includes the pharmacists and is called the Union Medico-Pharmaceutique. It has been victorious in a recent conflict with the local Pasteur Institute, in charge of Calmette, which had opened a dispensary where persons with tuberculosis could be diagnosed and treated. The Union claimed that the Institute had been organized for scientific research, and that it had no right to undertake practical clinical work besides.

Pensioned Patients.—The enterprise of the Sociedad de Med. e Cir. of Sao Paulo in Brazil, is evidenced by the unanimous adoption of a resolution to pension a patient whose stomach was removed fifteen months ago, in order to keep her in sight and ensure her appearance at the sessions when desired. She now eats the family diet and has increased 12 kilograms in weight. A fund was established at the same time to pension other patients with unusual affections to keep them in town.

Pregnancy and Tuberculosis.—Several obstetricians have recently published statistics in regard to the effect of pregnancy on tuberculosis, but Maragliano remarks that an obstetrician is not qualified to judge. He reiterates his well-known views on the perils of pregnancy for tuberculous women. If the disease is stationary, there is danger of arousing it, or if it is evidently progressing, even in the incipient stages of the disease, the girl must not marry, the pregnant women should be aborted, the parturient should never suckle her child. But, after several years of improvement, the question as to whether a tuberculous woman can undertake the function of maternity, is open to discussion. The physician—not the obstetrician—is the only qualified judge of the advisability of allowing a pregnancy to continue under these circumstances.

French Congress of Hypnology and Psychology.—The tenth annual congress was held at Paris in July. P. Farez described the cure of uncontrollable vomiting in a virgin of 20 and in a ii-para, 35 years of age. Both were cured by painting large and the outlook in the right directions to catch the best summer exposure. There is individualization, as there should be, for each patient, but no special crowding of food as there is at some institutions, simply three good meals a day, and graduated exercise by walking according to each one's ability and condition. He scouted at the use of antiseptics, saying soap and water were good enough to clean up a room with after a patient had died in it. We could not help reasoning that if he had the dryness, sunshine and altitude which we get east of the Rocky Mountains, he would have the best place in the world in which to treat consumption. But then, if he had these, he would not have his heavy foliage and grassy hillsides and the nearness to the people he would serve. Of course, devoting his attention to only 45 patients, all he can accommodate at one time, he is very successful.

The next institution we visited was Dr. Hettinger's, farther down in the same valley. It is a compromise between Dr. Walther's and the first two mentioned. But it is a clean, airy, well-lighted and well-cuisined sanatorium, which, because of its similarity in many respects to his own "Home," in Denver, much delighted the esthetic mind of Mr. Oakes. We could not help noticing the double windows, and I learned that sometimes in winter the storms are so severe that these are deemed necessary. I had heard of the double windows generally used by the Swiss, to which Dr. Tucker Wise attributes the frequent occurrence of tuberculosis in that otherwise healthy country.

Well, they are all coming around to the same belief that we physicians in Colorado have been preaching these many years, namely, pure air and an active outdoor life in that climate where it can be had the easiest and most comfortably.

Yours respectfully, CHARLES DENISON, M.D.

Vivisection—A Reply to Dr. Keen.

TOLEDO, OHIO, Aug. 21, 1901.

To the Editor:—I have read the communication of Dr. Keen, published in your issue of August 10, and already applications have been made by members of the medical profession for literature concerning the subject of the controversy—human vivisection.

As the American Humane Association considers this matter one of vital importance, its executive committee has, after amendment and revision, just printed that Review of Dr. Keen's letter upon which he, in his last communication, comments; and in order to do him justice, the Association has added his first letter, which he has called "The Misstatements of Antivivisectionists." These two documents in one pamphlet can be secured gratis by any physician in the United States who will send his professional card to "The Special Committee," Postoffice Box 215, Providence, R. I. For those medical men who carefully read this pamphlet, it would seem to me that Dr. Keen's latest letter will need no reply.

If your space would permit, there could be pointed out in this document some very serious misquotations, leading him to misstatements and comments which ordinarily would be without excuse. I prefer, however, to join with his many friends in speeding Dr. Keen in his journey around the world, and wishing him a pleasant voyage and a safe return; to leave his misconceptions and mistakes to his own sober judgment, and the rectification that time will surely bring.

This Association can have no quarrel with the medical profession. It believes, rather, that in condemning and opposing the use of human beings, chiefly women and children, for experiments dangerous to life and health, it has the sympathy of the great majority of the physicians of the United States.

Nothing can so surely and utterly destroy all confidence in the personnel of the medical profession, and in the security of our hospitals and asylums, as a well-founded impression that every patient, young or old, strong or feeble, high or low, rich or poor, is not absolutely secure in all of his personal rights.

He who, in the pretended interests of science, consciously aids in the destruction of this confidence or security is, in my judgment, little less than an enemy of his race.

Yours most truly, JAMES M. BROWN,
President American Humane Association.

[We shall be glad to see the publication of Dr. Keen's letters in full with the Humane Association's pamphlets. We have no fear of the judgment of any unbiased individual who is fully informed on the subject, and think that any such one who reads Dr. Keen's replies, as well as the publications referred to by our correspondent, will be able to form his own opinion. Knowing as we do the erroneous character of some of the statements in the Humane Association's pamphlet, some of them based on misapprehensions patent to any well-read physician, it seems to us that Dr. Keen's letter can have no reply. If there is an impression abroad that the rights of the hospital and asylum patients are not regarded by the medical profession in this country, it is due to sensation-mongering newspapers and to misstatements, whether wilful or not we do not care to say, of such publications as those that called out Dr. Keen's replies.—EDITOR.]

Book Notices.

LECTURES ON NASAL OBSTRUCTION. By A. Marmaduke Sheild, M.B. (Camb.), F.R.C.S. (Eng.), Surgeon to St. George's Hospital, London. With 1 Colored Plate and 27 Illustrations in the Text. Cloth. Pp. 106. Price, $1.50. Philadelphia: P. Blakiston's Son & Co. 1901.

This little work is intended primarily for the student and general practitioner. The author is conservative in operative treatment, particularly with regard to septal spurs; he prefers, however, the galvanocautery in hypertrophic rhinitis and seldom uses an acid. The origin of nasal polypi is attributed in most instances to irritation of the mucous membrane by a concomitant bone necrosis.

A PRACTICAL TREATISE ON GENITO-URINARY AND VENEREAL DISEASES AND SYPHILIS. By Robert W. Taylor, A.M., M.D., Clinical Professor of Venereal Diseases at the College of Physicians and Surgeons, New York. Second Edition, thoroughly Revised. With 138 Illustrations and 27 Plates in Colors and Monotones. Cloth. Pp. 722. Price, $5.00. New York and Philadelphia: Lea Brothers & Co. 1900.

This is not a mere aggregation, but a discriminating digest of the latest knowledge of the subject and there is no chapter in the work from which the reader may not learn something new. It is a most satisfactory text-book, and is modern in every particular. It is most comprehensive in its scope, sound and practical in its teachings, and we predict for it a wider circulation than the first edition enjoyed, and in time an urgent demand for a third edition.

THE TREATMENT OF FRACTURES. By W. L. Estes, A.M., M.D., Director and Physician and Surgeon-in-Chief of St. Luke's Hospital, South Bethlehem, Pa. Cloth. Pp. 216. Price, $2.00. New York: International Journal of Surgery Co.

This work of 216 pages is a publication in book form of a series of papers by the author which appeared in the *International Journal of Surgery*. No attempt is made to discuss in a complete manner the entire subject of fractures, and much, therefore, which pertains to the pathologic side of the subject has been omitted. The work is essentially one on treatment, and this phase of the question is handled in an eminently practical manner by one who has had a considerable experience in the management of these acute accidents.

The aim of the author has evidently been to the practical rather than to the scientific, and he has limited himself almost entirely to a description of his own methods.

DISEASES OF THE ANUS AND RECTUM. By D. H. Goodsall, F.R.C.S. (Eng.), Senior Surgeon (late house surgeon) to St. Mark's Hospital for Fistula and Other Diseases of the Rectum, and W. Ernest Miles, F.R.C.S. (Eng.), Surgeon (outpatients) to the Gordon Hospital for Diseases of the Rectum. In Two Parts (Illustrated). Part 1. Cloth. Pp. 311. Price, $2.50. London, New York and Bombay: Longmans, Green & Co. 1900.

Part I deals with the anatomy, general diagnosis, abscess, fistula, fissure and hemorrhoids. The subjects are, in general, very well handled. In the treatment of hemorrhoids preference is given to the operation by ligature to the exclusion of all other methods. While this is the best method in the majority of cases, there are other methods which certainly are of use in special cases, and in a work of this character these methods deserve more attention than to be dismissed as useless by a three-line notice. The illustrations, which are quite numerous, are very good, most of them being reproductions of photographs.

With Part II, which is in preparation, the work will be quite complete and worthy of careful reading.

Surgical Applied Anatomy. By Sir Frederick Treves, K.C.V.O., C.B., F.R.C.S., Sergeant Surgeon to H. M. the King. New Edition, Revised by the Author. With the Assistance of Arthur Keith, M.D., F.R.C.S., Lecturer on and Senior Demonstrator of Anatomy at the London Hospital. Illustrated with 80 Engravings. Cloth. Pp. 571. Price, $2.00. Philadelphia: Lea Brothers & Co.

This edition has been revised throughout, certain sections have been rewritten and much new matter added; it is well up to date. The usefulness of the work can be questioned by no one; it is a more attractive presentation of the most important facts of anatomy, especially in their practical bearings. It is, therefore, a convenient reference book and a valuable suggester of much information that is not always easily brought out, so to speak, from the dusty pigeon-holes of the memory. Sir Frederick Treves, as one of the first of British surgeons, is especially competent to furnish such a work, and this latest revision will be of value to practitioners as well as students preparing for their examinations. The illustrations, while not very numerous, have been considerably increased in this edition, and are specially serviceable and well selected.

The Diagnostics of Internal Medicine. A Clinical Treatise on the Recognized Principles of Medical Diagnosis, Prepared for the Use of Students and Practitioners of Medicine. By Glentworth Reeve Butler, A.M., M.D., Chief of the Second Medical Division, Methodist Episcopal Hospital. With 5 Colored Plates and 246 Illustrations and Charts in the Text. Cloth. Pp. 1059. Price, $6.00. New York: D. Appleton & Co. 1901.

Works on diagnosis are comparatively numerous at the present time, but each new one has its special features of interest and value. The present volume, while less complete in its scope than some, covers the greater portion of the field of internal medicine in a very satisfactory way and undoubtedly will be found by many more acceptable than other works. It is particularly strong in its illustrations; these are generally very well selected to illustrate the text, which itself is clear and readable. The arrangement of the work is also one that will possibly find favor with many readers, especially students and general practitioners, much the larger part being given to the "Evidences of Disease" or general symptomatology and this is followed by a shorter section on special diagnosis, differential and direct. The treatment of the special subjects in this department is less elaborate than in some other works, but the main points appear to be generally well stated. There seems to be an omission in the absence of descriptions of the usual urinary and other tests. While mental disorders are left out, it would not have been amiss to have included some notice of a condition like paresis, which has a more or less definite pathology and is often confused in its early stages with certain other nervous disorders. Syphilis of the nervous system might have also received fuller treatment.

Taking the work as a whole it may be said to meet most of the requirements of a work on the diagnosis of non-surgical diseases and to possess special merits in some particulars, more especially in its first section. It is well worth a place in the physician's library.

Uterine Tumors: Their Pathology and Treatment. By W. Roger Williams, Fellow of the Royal College of Surgeons. Cloth. Pp. 359. Price, $3.00 net. New York: William Wood & Co. 1901.

This monograph opens up with a brief description of the development of the uterus and its anatomic relations. Uterine myomata are then considered in an exhaustive manner. The histology of the uterus in relation to its neoplastic pathogeny, the influence of aberrant elements, "rests," developmental irregularities, gross malformations, and the microbic theory are all considered under the etiology of these new growths. The author thinks that suppressed maternity and sterility "are among the most important factors in the genesis of these tumors."

Is it not more probable that the diminished fertility of these patients is due rather to the pathologic state of the uterus superinduced by the presence of the new growths? Nor does his point find support when he attempts to show the hereditary nature of these growths, for he states "myomatous patients come of large families, for those in my list averaged 8.1 members each." Concerning the etiology of carcinoma he disregards entirely the modern tendency to ascribe this to extrinsic or microbic influences, and says the "great relative proneness of the epithelium of the uterine mucosa to take on proliferative cancerous changes is due to the awakening in its constituent cells of potentialities" derived from their parent cells in the genital ridge which are akin to those which furnish the ovigerms. But such an explanation explains nothing, and will not restrain in the least the earnest search for the cause of cancer which must some day be revealed.

In the operative removal of the cancerous uterus, stress is well laid on the necessity of extending the operation to the removal of the para-uterine tissues and the lymph glands, if better permanent results are to be hoped for.

In the production of this volume the author has labored well and earnestly and given to the profession a work of value.

Miscellany.

The Consumptives Picnic Grounds.—The success of the day-resort for consumptives at Berlin has proved so encouraging that three more have been founded, two for men and two for women. They are all in easily accessible groves on the outskirts of the city and are provided with a kitchen, etc., to supply a nourishing lunch at a minimum price. They were organized by the Red Cross Society.

Success of Organized Effort in Lille.—The local medical society of Lille, France, includes the pharmacists and is called the Union Medico-Pharmaceutique. It has been victorious in a recent conflict with the local Pasteur Institute, in charge of Calmette, which had opened a dispensary where persons with tuberculosis could be diagnosed and treated. The Union claimed that the Institute had been organized for scientific research, and that it had no right to undertake practical clinical work besides.

Pensioned Patients.—The enterprise of the Sociedad de Med. e Cir. of Sao Paulo in Brazil, is evidenced by the unanimous adoption of a resolution to pension a patient whose stomach was removed fifteen months ago, in order to keep her in sight and ensure her appearance at the sessions when desired. She now eats the family diet and has increased 12 kilograms in weight. A fund was established at the same time to pension other patients with unusual affections to keep them in town.

Pregnancy and Tuberculosis.—Several obstetricians have recently published statistics in regard to the effect of pregnancy on tuberculosis, but Maragliano remarks that an obstetrician is not qualified to judge. He reiterates his well-known views on the perils of pregnancy for tuberculous women. If the disease is stationary, there is danger of arousing it, or if it is evidently progressing, even in the incipient stages of the disease, the girl must not marry, the pregnant women should be aborted, the parturient should never suckle her child. But, after several years of improvement, the question as to whether a tuberculous woman can undertake the function of maternity, is open to discussion. The physician—not the obstetrician—is the only qualified judge of the advisability of allowing a pregnancy to continue under these circumstances.

French Congress of Hypnology and Psychology.—The tenth annual congress was held at Paris in July. P. Farez described the cure of uncontrollable vomiting in a virgin of 20 and in a ii-para, 35 years of age. Both were cured by painting the region over the stomach and esophagus with collodion colored with methylene blue. This blue collodion he considers a very important aid in psychic treatment. The intense color attracts the attention and the slight discomfort caused by the retraction of the collodion assists in the impression produced. The therapeutic suggestion is thus sustained, amplified and reinforced. Lépinay described various hysteric accidents caused in animals by emotions, scolding, electricity, castration, etc. Many animals are killed on suspicion of rabies when they are merely exhibiting transient hysteric convulsions. Manfroni related an instance of analgesia suggested to a patient while he was in a normal sleep. When he awoke he was much astonished to find that he experienced no pain from a lesion extremely painful hitherto. Bianchi delivered an address on "Cerebral Phonendoscopy," Regnault on the "Doubling of the Personality," and others described a number of cases of kleptomania, puerperal eclampsia, spasmodic contracture, etc., cured by suggestion.

Formaldehyd in Milk.

The adulteration of milk by the use of formaldehyd is probably becoming much more common than is generally suspected. For a time its use was a "trade secret," but it has been so thoroughly advertised that every obscure individual who has a milk route is now familiar with the preservative qualities of formaldehyd. In our large cities the health officers are on the watch, and hence in these its use is being curtailed, but in the smaller towns and villages the people have not this protection. It would be well, therefore, for physicians to guard against this and keep it in mind when mysterious illness develops in milk-users. They should also be prepared to make an analysis of milk at any time as to its freedom from the drug. This is a simple procedure, and yet one that requires considerable technical skill in the use of some of the tests. We copy from the *Lancet-Clinic* the various methods for testing formaldehyd as laid down by Herman Harms, some of which are quite simple:

Rimini Test.—A—Phenyl-hydrazine muriate, 0.5 gm.; distilled water, 100 c.c.; dissolve. B—Sodium nitroprussid, 0.5 gram; distilled water, 30 c.c.; dissolve. C—Soda U. S. P., 15 gm.; distilled water, 60 c.c.; dissolve. To 15 c.c. of the suspected milk in a test-tube add 10 drops of A, mix and add 3 drops of B; mix and let 5 drops of C run in slowly on the side of the test-tube. In the presence of formaldehyd a blue color is instantly produced, changing, on standing, to red. On adding to the mixture of milk and solution A 2 drops of ferric chlorid solution, and then about 2 c.c. of concentrated hydrochloric acid, a red color is produced, which later changes to orange-yellow. In sour milk the above-mentioned blue is supplanted by green. The Rimini test is easily applied, and readily detects formaldehyd when present to the extent even of 1 part in 25,000 or 30,000.

Phloroglucin Test.—Dissolve 1 gram of phloroglucin in 100 c.c. of distilled water. Put 10 c.c. of the suspected milk in a test-tube and add 5 c.c. of the phloroglucin solution; shake and add 1 c.c. of solution of potassa, U. S. P. If formaldehyd is present a red color is developed at once, fading, usually, within five or ten minutes; hence, the color must be observed at once. One part in 20,000 gives a decided reaction.

Hehner's Test.—To 15 c.c. of concentrated sulphuric acid in a test-tube add 1 or 2 drops of ferric chlorid test solution, U. S. P., and mix. Then pour upon this, in such manner as not to mix the layers, the suspected milk. A violet color indicates the presence of formaldehyd. In the case of cream, dilute the cream with an equal volume of water, and then apply the test as above described. The violet color is sometimes produced at once, but oftener not for five or ten minutes, and sometimes not for an hour or so, depending upon the amount of formaldehyd present. By this test a part in 10,000 or 15,000 is readily detected.

Liebermann Phenol Test.—In the presence of small traces of formaldehyd, distill off from the milk a few cubic centimeters and add to this one drop of very dilute aqueous phenol solution. Then pour this mixture slowly upon concentrated sulphuric acid in a test-tube solution so as to form a layer. A bright crimson color appears at the zone of contact. This is easily seen in as little as 1 part in 200,000, and in greater proportion in 1 to 100,000. There is a milky zone above the red color, and, if more concentrated, there will be a whitish or pinkish precipitate. Sometimes the zone will appear in about one hour, one-tenth of an inch below the line of contact.

Hydrochloric Test.—Fifteen or 20 c.c. of suspected milk, together with 2 or 3 c.c. of strong hydrochloric acid, are boiled for a few minutes in a test-tube. A red coloration indicates formaldehyd. Other tests are known, but they are more complicated and require apparatus or reagents not kept by the average pharmacist. The above tests are all simple in their application and afford a ready means of detecting formaldehyd in milk and cream.

Remarks on the Foregoing Tests.—The Rimini test is highly recommendable. The reaction in sweet milk appears rapidly and with certainty. Hehner's test, as well as the phloroglucin and phenol tests, are very reliable and are all extremely sensitive. The hydrochloric-acid test is very simple, but is not to be depended upon. It may show formaldehyd in most instances; however, cases have come under our observation when it has utterly failed to show the reaction, probably because of the milk having undergone some unknown changes. The Liebermann test is simple, delicate, and shows formaldehyd very readily.

As corroborative evidence, it is well, after the tests are finished, to let the suspected milk or cream stand in a warm place for 24 hours. A pure sample will invariably turn sour and separate. A sample which has been "doctored" with formaldehyd, however, will show, at the end of 24 hours, but a very slight separation, if indeed any at all, and will have but a slight odor.

A Word of Caution.—It is desirable that all test solutions be freshly prepared, especially the nitroprussid of sodium solution in the Rimini test; and that the suspected sample be as fresh as possible. Sour samples are difficult to test, and may yield variable results, because in these formaldehyd has been oxidized, and is no longer present as formaldehyd. In carrying out the tests for formaldehyd, it is advisable to work side by side the suspected sample and the one known to be pure. Finally, do not expose your tests or have your milk placed where a bottle of formaldehyd is being opened, for the vapor is very penetrating, and you may thus be easily led to misleading results. When formaldehyd has been found to be present by at least three of the aforementioned tests, it may be considered that its presence has been shown.

Married.

J. L. Dusic, M.D., to Miss Lavina Heyner, both of Cleveland, Ohio, August 12.

William F. Bay, M.D., to Miss Nellie H. Davis, both of Columbus, Ohio, August 15.

Ephraim Cutter, M.D., New York City, to Mrs. Anna L. Davison, of Boston, August 10.

John D. Todd, M.D., Trezevant, Tenn., to Miss Emma R. Hart, of McKenzie, Tenn., June 5.

Marie Merrill, M.D., late assistant at St. Peter (Minn.) State Hospital, to William G. Hyde, of McMillan, Mont., at St. Paul, Minn., August 8.

Deaths and Obituaries.

Thomas J. Turner, M.D., University of Pennsylvania, Philadelphia, 1851, captain and medical director, U. S. Navy, retired, a member of the American Medical Association, died at Mackinac Island, Mich., whither he had gone for his health from his home in Coldwater, Mich., August 21, aged 72. He was appointed to the navy in 1853; was fleet surgeon on the *Asiatic station* in 1875 and 1877; a member of the examining board at Washington thereafter; secretary of the National Board of Health during the yellow fever epidemic of 1877, and was retired in 1891.

James C. Crenshaw, M.D., University of Louisville, 1887, for several years a practitioner in Memphis, Tenn.; thereafter assistant superintendent of the Arkansas State Hospital for the Insane, Little Rock, and for the last year a practitioner of Dermott, Ark., died suddenly at his home in that place, August 16.

Thomas Masters Markoe, M.D., New York City, died August 28, at Easthampton, L. I. A longer notice will appear next week.

David Wooden, M.D., Louisville Medical College, 1885, died suddenly at his home in Grayville, Ill., August 13, from gastro-enteritis, aged 41. At the time of his death he was president of the Board of Education.

Frederick G. Flesher, M.D., University of California, San Francisco, 1893, coroner of Rice County, Minn., died at his home in Faribault, after a short illness, from meningitis, August 14.

Benjamin H. Kittrell, M.D., Tulane University, New Orleans, 1897, of Winona, Miss., who served in the Spanish-American war, died August 17 at Fourth Lake, New York.

David Magie Cory, M.D., College of Physicians and Surgeons, New York, 1866, New York City, died August 19, aged 58.

Alexander McBride, M.D., a pioneer physician of Macon County, Ill., died at his home in Decatur, August 14, aged 71.

S. T. Morehead, M.D., formerly of Allensville, Ky., died suddenly in Nashville, Tenn., August 14, from heart disease.

Jacob Hartmann, M.D., St. Louis Medical College, 1875, of New York City, died in that city, August 18, aged 63.

John L. Dodge, M.D., New York University, 1846, died at his home in Groton, Conn., August 18.

Societies.

COMING MEETINGS.

American Association of Obstetricians and Gynecologists, Cleveland, Ohio, Sept. 10, 1901.
American Academy of Railway Surgeons, Chicago, Sept. 12-13, 1901.
Mississippi Valley Medical Association, Put-in-Bay, Sept. 12-14, 1901.
American Public Health Association, Buffalo, Sept. 16-20, 1901.
Medical Society of the Missouri Valley, St. Joseph, Mo., Sept. 19, 1901.
Medical Society of the State of Pennsylvania, Philadelphia, Sept. 24-26, 1901.
American Electro-Therapeutic Association, Buffalo, Sept. 24-26, 1901.
Roentgen Society of the United States, Buffalo, N. Y., Sept. 10-11, 1901.
Rocky Mountain Inter-State Medical Association, Denver, Colo., Sept. 3-4, 1901.
Conference of State and Provincial Boards of Health of North America, Niagara Falls, Sept. 13-14, 1901.

Arkansas Colored Medical Association.—The seventh annual meeting of this Society was held in Hot Springs, August 15. Dr. Claude M. Wade, Hot Springs, was re-elected president and Dr. George W. Hayman, Little Rock, elected secretary.

Donley County (Texas) Medical Society.—This Society was organized at Clarendon, August 15, with the following officers: Dr. Joel P. Morris, Clarendon, president; Dr. Jerome D. Stocking, Clarendon, vice-president, and Dr. T. W. Carroll, secretary.

Lake Keuka (New York) Medical and Surgical Association.—The second annual meeting of this Association was held at Grove Springs, August 13 and 14. Dr. Clair S. Parkhill, Hornellsville, was elected president and Dr. William W. Smith, Avoca, secretary.

Fergus County (Mont.) Medical Association.—The physicians of Fergus County held a meeting at Lewistown, August 1, for the purpose of organizing a county society. Dr. William A. Long, Lewistown, was elected temporary chairman and Dr. Solon B. Stone, Lewistown, temporary secretary.

Gallia County (Ohio) Medical Society.—This Society was reorganized at a meeting held in Gallipolis, Aug. 22, 1901, and the following officers elected: Dr. Jehu Eakin, Patriot, president; Dr. Rufus D. Jacobs, Vinton, vice-president; Dr. L. B. Turner, Bidwell, secretary, and Dr. J. B. Dustin, Bidwell, treasurer. As a special feature of this meeting, Dr. P. Maxwell Foshay, of Cleveland, addressed the society on "Medical Organization."

Medical Society of the Missouri Valley.—The fourteenth annual meeting will be held in St. Joseph on Thursday, September 19, and Eureka Springs, September 20 and 21. The 'Frisco railroad will carry members and their ladies free from Kansas City to Eureka and return. One fare for the round trip ($1.90) has been secured from St. Joseph to Kansas City. Pullman fare will be $1.00 each way, $2.00 for double berth, which must be remitted to the secretary before September 1, in order that extra cars may be provided for the party. A daylight ride on the return trip may yet be arranged, if a majority prefer it. One day's scientific session will be held in each city, and last day will be devoted to sight-seeing at the Springs. In the evening a reception will be tendered the association by the local profession and Commercial Club. The Western Passenger Association has granted a special rate of fare-and-one-third for round trip, on certificate plan from points in Missouri, Iowa, Kansas, Nebraska, Oklahoma, Arkansas, North and South Dakota. A cordial invitation is extended to the medical profession, and an interesting meeting is anticipated. —Dr. Charles Wood Fassett, secretary.

Therapeutics.

[It is the aim of this department to aid the general practitioner by giving practical prescriptions and, in brief, methods of treatment for the diseases seen especially in every-day practice. Proper inquiries concerning general formulae and outlines of treatment will be answered in these columns.]

Chloretone in Pertussis.

W. Lyon, of London, recommends the following combination containing chloretone to prevent the vomiting in pertussis:

℞.	Bromoformi	m. ii		12
	Chloretoni	gr. iss		09
	Tinct. aurantii	m. x		60
	Mucilag. acaciæ	m. xx	1	30
	Aquæ q. s. ad	ʒi	4	

M. Sig.: At one dose; or

℞.	Bromoformi	m. ii		12
	Chloretoni	gr. iss		09
	Tinct. aurantii	m. x		66
	Glycerini	ʒi	4	

M. Sig.: *At one dose.*

Treatment of Acute Rheumatism.

Dr. George Dock, Ann Arbor, in an interesting article in the *Phys. and Surgeon*, states that the first thing to be observed in the treatment of rheumatism is rest, however mild the symptoms may be. Flannel nightclothes should be worn. Rest for the affected joints should be especially considered. This can be secured by well-applied woolen bandages, and if necessary render the joint immovable by applying splints. The patient should be kept in bed as long as there is fever and joint pain. The diet in the febrile stage must be light, and water given freely. Tea, coffee and alcoholics should be avoided.

The bowels should be moved with small doses of calomel. As to the drug treatment, he recommends the salicylates, but emphasizes the importance of giving them in large doses. The system should be saturated. Not less than 120 grains should be given within twelve hours. He recommends sodium salicylate combined with an alkali such as sodium carbonate given similar to the following:

℞.	Sodii salicylatis	ʒii	8
	Sodii carbonatis	ʒii	8
	Aquæ camphoræ q. s. ad	℥vi	192

M. Sig.: One tablespoonful every hour in water.

He adds that patients with acute nephritis or old interstitial nephritis should not be subjected to the foregoing treatment.

Aspirin as a Substitute for the Salicylates.

Aspirin, which is a comparatively new preparation, is recommended as possessing the following advantages over the salicylates: It does not cause any irritation of the stomach, nor does it disturb digestion. It does not produce the tinnitus aurium. The heart's action is not affected by its use.

Aspirin is a white, crystalline powder soluble in 100 parts of water. Being a combination of acetic and salicylic acids it is used as a substitute for sodium salicylate, resorcin, salol, salophen and creosote, and should not be given in maximum doses with these preparations.

Treatment of Pruritus Ani.

The following gives great service in relieving the troublesome itching:

℞.	Alumnol	gr. xxx	2	
	Pulv. camphoræ	ʒiss	6	
	Lanolini q. s. ad	℥i	32	

M. Sig.: Apply locally night and morning.

To Relieve Burns.

The following containing hydrogen peroxid is recommended as an application for burns of the first or second degree:

℞.	Hydrogenii peroxidi	℥ss	16	
	Adipis canæ	℥i	32	
	Ol. rosæ	gtt. ii		12

M. Sig.: Apply locally.

The Treatment of Leg Ulcers.

Walbaum, in *Med. Rec.*, describes a dressing with which he states a cure is effected within three weeks. After thoroughly cleansing the skin, wet dressings of aluminum acetate are applied until the secretion has been somewhat checked and has lost its odor, which usually takes place in two or three days. A compress wet with spirits of camphor is then applied and covered with rubber protective, which in turn is surrounded with absorbent cotton and a bandage. The dressings should be renewed every second day.

Carbolic Acid in the Treatment of Eczema.

Carbolic acid has been employed in a very extensive manner in the treatment of different forms of skin diseases. Dr. J. F. Schamberg, as noted in the *Med. Standard*, states that the following renders good service as a lotion in the treatment of acute erythematous or papular eczema:

℞.	Acidi carbol.	gr. xxx	2	
	Acidi borici	ʒi	4	
	Glycerini	ʒi	4	
	Zinci oxidi	ʒii	8	
	Aquæ q. s. ad	℥vi	192	

M. Sig.: Apply locally night and morning.

In more chronic cases it should be used in greater strength as follows:

℞.	Acidi carbol.	ʒii	8	
	Glycerini	℥i	32	
	Etheris	℥i	32	
	Spts. vini rect.	℥vi	192	

M. Sig.: To be used locally.

In the subacute vesicular eczema he recommends the following ointment containing phenol and calomel:

℞.	Acidi carbol.	gr. x		66
	Hydrarg. chloridi mitis	gr. xx	1	33
	Pulv. amyli	ʒii	8	
	Pulv. zinci oxidi	ʒii	8	
	Petrolati	℥ss	16	

M. Sig.: To be applied locally.

The above is to be used in all forms except the very acute eczemas.

In other cases of subacute eczema he employs the following:

℞.	Acidi carbol.	gr. x		66
	Plumbi oxidi (C. P.)	ʒi	4	
	Petrolati	℥ss	16	
	Lanolini	℥ss	16	

M. Sig.: Cleanse the affected parts and apply locally.

Exercise in Treatment of Paralysis Agitans.

Dr. J. M. Taylor, in *Jour. of Ment. and Nerv. Dis.*, recommends a plan to overcome the muscular rigidity and impairment of movement. The treatment should consist of exercise. Passive movements and massage with oil inunctions. Passive movements, especially of the neck, back, and limbs, should be given. The spine should be extended by stooping, the legs and arms stretched to the greatest extent and deep breathing practiced. The most important movements to overcome the tremor are slow, *full, forcible* expansions and the attainment of normal position. He reports improvement in several cases in which the foregoing outline of treatment has been employed.

Treatment of Tinea Tonsurans.

Dr. Brown, in *Post-Grad.*, recommends the following in treatment of tinea tonsurans and facial erysipelas:

℞.	Acidi salicylici	gr. xx	1	33
	Chrysarobin	gr. xx	1	33
	Ichthyol	ʒi	4	
	Lanolini			
	Vaselini, āā	℥ss	16	

M. Sig.: Shave the scalp and rub the ointment over the entire surface.

A bandage covering the scalp should then be put on carefully to avoid any chance of the chrysarobin getting into the eyes. At the end of three days the bandage should be removed, the head washed and some emollient salve applied to check the dermatitis usually set up. After a few days the treatment is resumed if necessary.

Trichloracetic Acid in Hay Fever.

Dr. H. Krause, as noted in *Merck's Archives*, recommends the use of trichloracetic acid in 1 per cent. solution, to be snuffed up the nose as a cure for hay fever. During the past two years he has used it in more than thirty cases with good results. He states that improvement and cure follow in two to eight days.

Treatment of Rhus Toxicodendron Poison.

The following preparations are recommended in case of poison from rhus toxicodendron, to which not a few people are susceptible:

℞.	Ext. grindeliæ robustæ flu.	ʒvi	24	
	Aq. menthæ *pip.*	℥iss	48	
	Aquæ rosæ	℥iv	128	

M. Sig.: Apply freely on cloths; or:

℞.	Plumbi acetatis	ʒss	2	
	Tinct. opii	℥ss	16	
	Aq. destil. q. s. ad.	℥viii	256	

M. Sig.: Apply externally in mild cases; or:

℞.	*Ichthyol*	*ʒii*	8	
	Aquæ	℥iv	128	

M. Sig.: Apply externally every three or four hours.

Treatment of Acne Rosacea.

In the treatment of acne rosacea much weaker local applications should be employed than in acne vulgaris. The best results in the former are obtained according to A. Brownlie, in *New York Lancet*, by a combination of local and internal treatment and where the skin is extremely tender internal treatment alone. His plan of treatment is the use of ichthyol in doses of 5 grains after meals three times a day, increasing to 10 grains. Every night and morning the face is steamed for fifteen minutes, and ichthyol salve afterwards applied, which he often combines with ammoniated mercury. The diet must be carefully guarded.

To Prevent the Shedding of Hair.

Dr. David Walsh, of London, according to the *Med. Standard*, recommends the following as a lotion, stating that it is preferable to an ointment, especially in the case of women:

℞.	Acidi salicylici	ʒiii	12	
	Acidi carbol.	ʒi	4	
	Olei ricini	ʒiii	12	
	Spts. vini rectif. q. s. ad	℥vi	192	

M. Ft. lotio. Sig.: Apply locally once or twice daily.

Treatment of the Paroxysms in Pertussis.

The following is recommended by Shoemaker:

℞.	Tinct. lobeliæ	ʒii	8	
	Sodii bromidi	ʒiii	12	
	Spts. etheris nitrosi	℥i	32	
	Syr. limonis q. s. ad	℥iii	96	

M. Sig.: One-half to one teaspoonful every one or two hours.

Epistaxis in People Beyond Middle Age.

Dr. George Coates, in London *Lancet*, states that he has made a study of five cases of epistaxis occurring in the aged, and has observed the cause to be mainly the same in each case, namely: Long-continued high arterial tension, some sudden cardiac disturbance; a congested condition of the venous circulation, with a leakage from an over-filled vein. He treated the attack locally to check the hemorrhage and as prophylactic measures he employed remedies which influenced the general circulation. The important thing being to empty as much as possible the venous circuit, he administered drugs which dilated the arterioles, thus relieving arterial tension, lessening the heart's labor and consequently relieving the congestion in the venous circuit. To meet these indications nitroglycerin or amyl nitrite was very properly used. As heart tonics he employed strychnin and strophanthus. The latter ranks close to digitalis as a heart tonic if prepared by reliable druggists, otherwise the results obtained will be a disappointment. It differs from digitalis in that it does not increase arterial tension by contracting the peripheral arterioles and is therefore better suited in those cases in which it was used by Dr. Coates.

Medicolegal.

Fifteen Thousand Dollars too Much for the Injuries.—The Supreme Court of New Jersey holds excessive the award of damages in the case of Spicer vs. Boice of $15,395, of which only $395 could be accounted for by disbursements. The plaintiff was 66 years of age. His physical injuries were painful, and to some extent permanent; but, while they had impaired, they had not destroyed any function or faculty. Under these circumstances, the court makes a remittitur of $7,500, the condition of letting the verdict stand.

Showing Extent of Injuries by Movement of Arm.—The Supreme Court of Minnesota holds, in the personal injury case of Adams vs. the City of Thief River Falls, that there was no error in permitting the plaintiff to illustrate her power to use her arm, claimed to have been permanently injured in an accident, by movements thereof at the trial and before the jury, she having been allowed to illustrate, by the movement of her arm in raising and lowering it before the jury, the nature and extent of the injuries which, under her claim, were sustained by her. Such experiments, the supreme court holds, were permissible and within the proper exercise of the discretion of the trial court.

Disciplinary Power of State Board of Health.—The question presented for decision in the case of the State Board of Health vs. Ross was whether, under the present act of the legislature of Illinois to regulate the practice of medicine, in force July 1, 1899, the state board of health has power to discipline and revoke the certificates of persons who had been licensed to practice medicine and surgery by the board prior to that date. Section 6 of the act provides that the board may refuse to issue the certificates provided for in the act in certain cases, and "may revoke such certificates for like causes." The appellate court held that this power of revocation plainly referred to certificates issued under the act, stating that if it was the intention of the legislature to give the board of health the power to discipline the holders of certificates issued prior to July 1, 1899, and to revoke such certificates, it had certainly failed to express such intention by this act. If the consequences of interpreting the statute according to its plain and obvious meaning are likely to prove disastrous to the people of the state at large, as contended by counsel, and as would seem not improbable, considering the large number of physicians and surgeons throughout the state, and the temptations to obtain money and practice by a resort to dishonorable conduct which are supposed to beset professional men, the responsibility, the court continued, must rest with the legislature, and not the courts. If the tendency of a law is vicious, the stricter its enforcement the sooner it will be amended or repealed. So the court answered the question raised in the negative. And the opinion of the appellate court is now adopted by the Supreme Court of Illinois, which affirms its judgment. The supreme court merely adds to that opinion that it has carefully examined all of the questions involved, and considered the criticisms of the opinion by counsel and their arguments against the correctness of the same, and is of the opinion the conclusions reached and announced in the opinion are correct.

Pecuniary Value of a Woman's Life.—With striking unanimity have two different courts, in different states, reduced judgments for damages for the deaths of women. In the case of Oakes vs. the Maine Central Railroad Company, the deceased, who left as her beneficiary a healthy child 5 years of age, and whose husband and the father of the child was in poor health, was 35 years of age, in good health, a good milliner, a prudent and industrious woman and affectionate mother, possessing a fair education. Now, the expectancy of life of herself and the beneficiary, the probability of her surviving her husband and being the sole support of her child, the length of time that might reasonably be expected to elapse before the boy would be able to help his mother and care for himself, the possibility that in time she in her turn might become dependent upon him for her support, the loss of a mother's training and good influence, which would tend to make him a better man, and capable of acquiring more money—all these, the Supreme Judicial Court of Maine holds, were considerations in determining the amount of the pecuniary injury resulting to the beneficiary. At the same time, the damages, under the statute under which the action was brought, could not be punitive, neither could they be given for her physical pain and suffering, nor for the grief and sorrow of the child and husband who survived, but the sum given must be the present worth of the future pecuniary benefits of which the beneficiary had been deprived. Under all of these circumstances, the court holds that a verdict for $3,500 was excessive, and that a new trial must be granted unless all above $2,500 was remitted. Likewise, in the case of Rafferty vs. the Erie Railroad Company, where the deceased was a single woman, 45 years of age, who kept house for her three brothers and a sister, who were all single, the Supreme Court of New Jersey holds that, the damages being limited by statute, to the pecuniary loss sustained by the next of kin, a verdict for $5,000 was, under the evidence, excessive. It thinks also that $2,500 would be the limit of a proper assessment of damages in this case, and makes the acceptance of a reduction to that amount the condition of letting the verdict stand.

Restriction of Expert Evidence in Will Cases Urged.—The Court of Appeals of Maryland says, in the case of the Safe Deposit & Trust Company of Baltimore vs. Berry, that observation and experience teach that there is danger of reaching inaccurate conclusions as to a testator's mental capacity if much reliance is placed on expert testimony founded exclusively on mere hypotheses. The expert, not having seen the individual about whose sanity he speaks, must rely solely on hypothetical statements of facts assumed to have been deposed to by other witnesses, which facts may have been colored by the persons who narrated them, or may be erroneously interpreted in their presentation to the expert, while the expert himself may be mistaken in the deductions he draws, even when the facts have been accurately rehearsed. Added to these sources of uncertainty, there is, and probably it is quite natural that there should be, more or less unconscious bias towards the side upon which the expert is employed; and, as a consequence, it is no unusual thing to see equally intelligent and equally honest experts arriving at diametrically opposite conclusions from precisely the same hypotheses. This anomaly, however, is not confined to alienists, but exists among experts on handwriting and on other subjects as well. But it is, for all of these reasons, the court declares, of the utmost importance, when the testator is not present to speak for himself, or to be seen by the jury, or to be personally examined as to his mental condition, that especial care be taken by the courts to restrict, within the narrowest limits consistent with settled rules of law, what the court terms, this hazardous species of evidence. Now, it goes on to say, as the opinion sought from the expert must have relation to the subject-matter being inquired into, it is obvious that it must be based on the facts proved, or tending to prove which there has been some evidence offered. It can not be founded on the mere naked conjectures, conclusions, or inferences of witnesses, because those conjectures, conclusions, or inferences might not represent the real conditions which existed, and thus there might be substituted by the expert, for a deduction which he could have properly drawn from the facts as they really were, precisely an opposite conclusion, at variance with the facts, and utterly false, because deduced from erroneous premises. Then, if this be so, much more is it certain, it says, that it would be improper to ask an opinion on a conjecture or conclusion or inference, not of a witness, but of the counsel who propounds the interrogatory. Again, the court says that it is perfectly self-evident that a question which is propounded to prove is essentially inadmissible. That is to say, a hypothetical question obviously cannot assume as true the ultimate thing to be proved.

AMERICAN.

1. **Surgery of the Prostate.**—After reviewing the various methods of treatment of prostatic pathologic conditions, Wishard sums up by saying that operative procedures are of the greatest value when undertaken early and that when they are long deferred, serious resultant bladder, urethral and renal diseases make the outcome increasingly dangerous. Where the catheter has failed to give adequate relief, death is reasonably certain to occur before long, especially in cases where the urethra has greatly increased in length by elongation of its prostatic end, unless the suprapubic opening for either prolonged drainage or removal of obstruction is obtained. If the symptoms are not of a severe type and are not amenable to the catheter, and if the length of the urethra from the meatus to the point where the urine is obtained does not exceed nine inches a perineal opening generally affords opportunity for stretching the entire length of the prostatic urethra, for dividing the small collar-shaped growths around the bladder end of the canal, and for removing the small projections by the finger, forceps, or cautery. One-fourth or as asserted by some, one-third of the operative cases are suitable for perineal opening. If the suprapubic operation has been thoroughly done and the obstruction all removed, the patients afterward are assured of more perfect bladder function than by any other method. He thinks it must be conceded, however, that in view of the serious dangers involved, many patients should be subjected to nothing more than the formation of a suprapubic channel, as suggested by McGuire and modified by Morris. Morris' improvement lines the channel with skin, and hence it is not so apt to contract.

2. **Infection by Animals.**—The dangers of the spread of infection by domestic animals, birds, cats, etc., are remarked upon by Meany and probable instances related. He refers in conclusion to the principle of isolation now insisted upon by sanitarians and favors the tendency of well-to-do individuals to be treated in hospitals rather than at home.

3. **Hot Air.**—The hot-air treatment and its advantages are noticed by Wightman, who sums up as follows: 1. Dry heat is a valuable pain-reliever without any of the depressant effects common to drugs. 2. In connection with constitutional and medicinal treatment, we have in it a positive curative agent. 3. It is a stimulant to rapid repair and absorption. 4. It is one of the most valuable eliminative agents we possess. 5. Where indicated, it possesses a sedative action on the nervous system obtained by no other means.

4. **Dysentery in the Philippines.**—Bowman holds that Cruikshank's researches have shown that dysentery in the Philippines is not a single, but two distinct and separate diseases, acute dysentery due to the bacilli of Shiga, which does not produce abscess of the liver or ulcer of the colon but acts similar to cholera, though requiring four, six or twelve days before its termination or crisis; and amebic dysentery which invades the layers of the *colon* producing punched-out ulcers

and also invades the liver producing characteristic lesions. There are two varieties of the ameba which vary in nowise except in size, the pathologic variety somewhat larger than the nonpathologic, and these two varieties have been the cause of all the confusion regarding the ameba as the etiologic factor in dysentery. He submits the following conclusions: 1. The duality of dysentery is proved. 2. Acute dysentery is the result of infection with the bacillus of Shiga. 3. It is infectious in the same way that the bacillus of typhoid fever is infectious. 4. Amebic dysentery is caused by an ameba. 5. There are both a pathogenic and a non-pathogenic ameba, which fact has produced much confusion regarding the ameba as an etiological factor. 6. The lesions of amebic dysentery differ from those produced by the bacillus of Shiga. 7. The therapeutic agents generally used for the treatment of acute dysentery are in no way curative. 8. Magnesium sulphate should be included in this list. 9. Quinin solution is a specific for the amebic dysentery, but its employment in rapid, acute ulcerating cases is fraught with danger, and from the nature of the lesions it cannot be retained for a sufficient length of time to produce beneficial effects.

6. **Blood Alkalescence and Urinary Reaction.**—From two series of observations on himself Stern offers the following inferences; from the first series he concludes, 1. The higher degree of urinary acidity concurs with a lessened blood alkalinity and the increased alkalescence of the blood with a decline of the urine's acidity. 2. There is no permanent and absolute ratio between blood alkalescence and urinary acidity. 3. The blood, under normal conditions, possesses a certain inherent alkalinity. The degree of alkalescence possibly varies slightly for certain periods of the twenty-four hours, but the influence of the ingesta upon these variations is neither a material one nor always determinable. 4. The degree of blood alkalinity is normally not affected by the quantity of the ingesta. The quality of the nutritives may normally contribute toward the rise and fall of the blood's alkalinity, but only to a very limited extent. 5. A portion of the substances elaborated from the nutriment will be egested without having been conveyed to the blood. 6. Some of the nutritive material, isolated and not utilized in anabolism, may be transferred into the urine in a more direct manner, and thus the accidental variations in the urinary reaction may be partly explained. The second series of observations were taken with the object of rendering the urine alkaline and studying the eventual relationship between urine alkalinity and the concurring degree of blood alkalescence. He recapitulates the data from this in the following: 1. A number of drugs effect the alkalinization of the urine without causing a corresponding increase in the degree of blood alkalinity. 2. The transitory augmentation of blood alkalinity, recurring mostly during certain hours of the afternoon, seems to be the result of certain innate processes, which apparently proceed independently of the ingestion of food or drugs. 3. While a higher degree of urinary acidity may concur with a more marked alkaline condition of the blood, a lower degree of urinary acidity, called forth by the introduction of a drug, may coincide with a lower degree of blood alkalinity on one and the same day.

7.—This article has appeared elsewhere. See THE JOURNAL of August 10, title 58, p. 406.

8. **The Origin of Oxalic Acid.**—Austin's article is a review of Salkowski's investigations and a description of his methods, which lead him to the following conclusions: 1. Oxalic acid is derived from the carbohydrate group in albumins, presumably through the intervention of glycocoll by a process of splitting, through which the remainder is converted to urea, a vital process though imitated by strong oxidizing agents. 2. Oxalic acid may also be derived from uric acid by fermentative action and oxidizing agents, and perhaps also by vital processes. 3. Oxalic acid, present in many organs of the body, practically absent in the feces of animals fed on non-oxalic acid containing foods, yet ever present in the urine after long periods of fasting, may rightly be called a metabolic product and rightfully take its place with acetone, lactic, acetoacetic and oxybutyric acids as a measure of abnormal retrograde metamorphosis.

10. **Syphilis of the Liver.**—The first part of Einhorn's article reviews the literature on the subject and it seems that syphilis of the liver is not infrequent. He divides it into three classes: 1. Gummata. 2. Syphilitic cirrhosis. 3. Syphilitic disease of the liver belonging to either of the above groups, and accompanied with icterus, either acute or chronic. Several cases illustrating these groups are reported with diagrams illustrating the extent and character of the disease. In the majority of the cases pains in the right hypochondrium are present, either constantly or intermittently; in the latter case they are severe, resembling gall-stone colic. We also have digestive disturbances, eructations, constipation, and more rarely diarrhea. A feeling of tension in the upper part of the abdomen is often met with and general malaise, restless sleep, weakness, moroseness, etc., and gradual loss of weight. Icterus may be acute or become chronic. No matter to which one of the above groups the morbid process belongs, the organ is usually more or less swollen in the right mammillary line between the free border of the ribs. Gummata may be sometimes recognized as uneven, round, hard nodules on the surface. If there is a cirrhotic process a marked swelling is encountered and in advanced stages an amyloid degeneration occurs. The organ then presents a harder and smoother appearance than normally. Enlargement of the spleen is not of uncommon occurrence; ascites may occur late. Diagnosis can be most positively made where gummata exist with other signs of recent or present attacks of syphilis. It is more difficult when tumors are present without other signs of existing syphilitic processes or without history; specific treatment may be required to confirm it. It is less certain when we have simply an enlarged, somewhat indurated liver, with or without icterus. Syphilitic cirrhosis resembles the ordinary hypertrophic cirrhosis so much that they are hard to clinically distinguish. Gummata are usually confounded with malignant neoplasms. If the disease has lasted for some time, with syphilitic manifestations, and no considerable loss of weight, it is probably syphilitic, but a slow, steadily progressive affection of the liver without intermission and with loss of weight and strength, and with neoplasm, the condition is, practically speaking, malignant. According to Neusser an increase of eosinophile cells in the blood points to syphilis. Alcoholic cirrhosis may be confounded, but the antiluetic treatment or the history may help to decide. It would appear from the literature that the prognosis is rather grave, but Einhorn seems to think if the diagnosis is made before the patient loses too much strength and before grave symptoms have yet occurred, the prognosis is very favorable. Of the 10 cases he reports only one died, and even this one had been considerably benefited; all the others were either permanently cured or much improved. Treatment is necessarily specific; the iodids play an important rôle, and while these may alone be sufficient, he has seen the best results from the combined use of this drug with mercurial inunctions. Special symptoms should be attended to: Icterus can be helped by using glycerin, a teaspoonful three times a day, one-half hour before meals. Iron and arsenic for anemia; special measures for ascites may be required. Proper hygienic and dietetic treatment is essential.

11. **Pregnancy Following Myomectomy.**—A number of cases from the literature are reviewed by West, and one is here reported by him; 14 in all, with 18 pregnancies, 3 patients having been twice pregnant. Of the 3 patients who were twice pregnant there were 2 healthy children born and 9 healthy children born to 14 at normal term. Two children went to term and were born dead. There were 6 abortions, most occurring in the third or fourth months; while all the uteri had extensive scars, in only 2 cases was it necessary to use forceps. All the presentations were normal. In the author's case in which nine incisions had been made into the uterine tissue, the labor lasted twelve hours and expulsive force was ample, the only complication being a lacerated perineum.

13. **Malaria in Central America.**—Egbert finds that fleas are active agents in transmitting malaria in the region of Honduras, where he made his observations. Mosquitoes were almost unknown.

14. **Fibroma of the Mesentery.**—Murphy reports a case and discusses the condition. He has been able to find in the literature not more than 11 similar cases. The gravity of the operation for mesenteric fibroid or malignant tumor is considerable on account of the shock and hemorrhage. In most cases of simple and encapsulated fatty tumors and cysts, however, the conditions are entirely different from fibroma or malignant disease. Statistics show that 28 per cent. of the cases recover by simple aspiration. Where the cysts have been tapped and fixed in the abdominal wound, there has been a mortality of 5 per cent., while where it has been directly removed the death-rate has reached 52 per cent.

15. **Soda Cacodylate.**—After noticing the use of arsenic under various conditions, Heitzman reports brief histories of a number of cases where cacodylate of soda was used. He thinks the drug is eminently adapted to cases requiring large doses of arsenic and is absolutely safe even in massive doses, being apparently non-toxic. It may be given hypodermically in doses of 1.5 gr. daily and up to 6 gr. daily by the mouth or rectum.

17. **Limitations of Operative Work.**—Cartledge pleads for more conservatism in operation. He thinks that there has been too much of a craze for operating, especially in abdominal cases and too many tyros have attempted it. He says, given a case where the focus of virulent infection has suddenly emptied its contents into the peritoneal sac at some point, either at the appendix, a septic tube or an intestinal lesion, if the sepsis has rapidly augmented, spreading to the entire peritoneal covering, characterized by no adhesion of limitation and manifesting itself objectively by a pulse-rate of 140 or 160, great abdominal distention, paresis of the intestine from toxemia and gas which precludes the possibility of attaining results from purgation, and the destruction of abdominal breathing—under such circumstances he does not believe that any surgical operation which has for its purpose the administration of an anesthetic, opening the peritoneal cavity with its subsequent drainage, can be other than productive of the greatest harm and hasten the usual disastrous termination. In reply to the argument which is usually made, that if 2 patients out of 100 can be saved, operation would be still justifiable, he answers that from a painstaking observation of a number of cases he is led to the belief that 5 per cent. would be saved by Nature, aided by such measures as sustaining the patient's heart, saline infusion, etc. Of course, the question will arise as to the accuracy of the diagnosis, but he is sure that we have all in the past operated on many of these cases that were hopeless and have swelled our mortality list and brought surgery into disrepute. Other unfavorable conditions than general septic peritonitis are mentioned, such as jaundice, renal insufficiency, ovarian and uterine cancer; here we can hold out but little promise of any recovery.

19. **Expectant Treatment.**—Jacobi commences with reporting some of his own early mistakes which he says still reveal themselves on sleepless nights even after nearly half a century, and he lays down the following platform, which he thinks should be adopted by the profession: In order to obtain indications for treatment, make a diagnosis. That art is becoming both more accessible and, through honest and hard work, more easy with the aid of modern methods. Remember that most diseases have, indeed, a tendency to spontaneous recovery, but also that recovery is not always complete and that invalidism should not be invited through neglect of treatment. Complications are possible as long as an illness lasts, and with every day cut short, the dangers of an otherwise typical disease are diminished. The experience of old men in the profession who claim they employ less drugs with advancing years, means sometimes either an inability to master new methods of diagnosis, or the knowledge of new medicines or physical remedies. There is no one treatment for a disease adapted to every patient. There is no such thing as a uniform treatment for pneumonia, or for typhoid fever, or, even in spite of antitoxins, for diphtheria or tetanus. We should not try to treat the name of an illness, but the patient.

20. **Treatment of Insanity in the General Hospital.**—Brower points out certain defects in public hospitals for the insane at the present time, that they are too large for proper individualization, too far from the homes of the patients and antiquated, cumbersome, and unscientific in their methods of admission. Also their degradation by politicians which has been too much the case in some of the states. He believes in the advantages of treatment of insanity in general hospitals, in special wards if necessary.

21. **Ventrosuspension.**—From 212 cases of ventrosuspension tabulated from the case-books of Drs. Penrose and Beyea, Woods deduces the following conclusions: 1. That the course of subsequent pregnancies and labors do not seem to be impeded by this operation. 2. That the operation in the great majority of cases carefully selected gives excellent results, and the relief experienced is lasting. 3. That it restores the normal condition of the uterus, and does not substitute a fixed unnatural anteflexion. 4. That the risk is minimum, and the danger from hernia very slight. 5. That by including a small amount of muscular tissue we increase the strength of the ligament without risk to the patient.

23.—See abstract in THE JOURNAL of July 13, p. 137.

25. **Sodium Tungstate Test.**—Benedict has noticed the following in his experience with the sodium tungstate test for combined chlorid in chyme. He was surprised to find that using dimethylamidoazobenzol, the free HCl seemed to have entirely disappeared, that is to say, the red color was lacking from chyme in which sodium tungstate had been dissolved, though previously present, while the total acidity had not correspondingly decreased. He repeated the tests three times, once using heat to dissolve the sodium tungstate. In all three instances the results agreed within the usual limits. The total acidity by phenolphthalein was 88 to 90 degrees free HCl by dimethylamidoazobenzol 50 to 60 degrees. After adding sodium tungstate the diminution of acidity was from 20 to 30 degrees. The diminution corresponding to combined chlorids by alizarin was 19 degrees. The large variation in the application of the tungstate test was one of method, not of inaccuracy. The lower reading—higher reading of total acidity—occurring when the first appearance of a distinct reaction with phenolphthalein was noted; the higher reading —lower total acidity—occurring when, after a lapse of 5 to 10 minutes, repeated increments of sodium hydrate solution were added as the end reaction faded. This fading of end reaction always occurs to some extent, especially when unfiltered chyme is used, owing to the slow neutralization of undissolved particles of proteid. In the present instance the chyme was decanted but was unusually free from such particles. The same chyme, without adding sodium tungstate, did not show a corresponding recrudescence of the end reaction. This phenomenon could not be due to an imperfect preliminary solution of sodium tungstate, as just the opposite effect would have been produced by the gradual solution and consequent diminution of acidity. His first thought, on noting the absence of color with dimethylamidoazobenzol was that the free HCl had also been neutralized, but this was obviously not the case, as the whole diminution of acidity did not equal that due to free HCl.

27. **Incudectomy.**—Progressive hardness of hearing or so-called chronic catarrh of the middle ear is, according to Burnett, associated with impaction of the stapes, and its liberation by the removal of the incus and consequent interruption of the retractive power of the tensor tympani, relieves the condition tinnitus aurium, and ear vertigo disappears. While it can improve the hearing only slightly in the ear affected, the progressive nature of the disorder is altered and the disease arrested. He has been able to observe closely some of the cases first operated on 13 years ago and finds

foods. One hundred and fifty-seven cases were of twenty-four hours' duration before first seen; 197 had been ill from two to five days, and 76 from five to ten days; 111 had had diarrhea over ten days, and 11 had been ill for two weeks. With some there was simply so-called dyspeptic diarrhea with moderate fever and slight prostration, others had been ill for several days with high fever and were in a critical condition. Nearly one-half recovered within a week. Quite a number lingered along until the fourth or fifth week and some for several months. In 56 the treatment was not continued. Out of 449 treated to the conclusion of their illness, 10 died, the death-rate being a little over 2 per cent. There was one invariable rule of treatment and that was to stop the milk at once. It would be impossible to the great mass of physicians to differentiate bacteriologically the nature of the infection in a large proportion of cases; this has been impressed upon him by considerable autopsy experience. We learn that every case of summer diarrhea must be looked on as dangerous and treated vigorously whether the initial symptoms are mild or severe. He doubts whether, in the majority of cases, the streptococcus or colon bacillus play a very important part. The average case is of gradual onset. If the milk is discontinued, a substitute must be found and the one he finds most useful is cereal water, usually barley water, and where this does not answer, rice water. The directions are: Robinson's baked barley flour, two tablespoonfuls, water one pint, boil for twenty minutes, strain and add water to make one pint when the cooking is completed. Rice is similarly treated. Brandy and whiskey should never be given to children with summer diarrhea, as the dangers of nephritis and stomach involvement are enough without provoking them with liquors. Animal broths should not be added to the diet in too large amounts on account of their laxative effects, but he uses them moderately and with care. Brandy and egg water mixture, so popular with many, is an atrocious milk substitute. Dextrinized gruels have a useful field in summer diarrheas, the dextrinization being of value as it offers more concentrated nourishment. Care should be taken that the cereal water is not at a higher temperature than 100 F. The substitute diet should be allowed to be given at two-hour intervals, if the child will take and retain it in good quantities. Boiled water may be given at any time. The patient should be kept in the largest room, and if there is fever, sponged in cold water for fifteen minutes several times a day. The milk diet is resumed gradually, diluting the barley water, with slight increase every day or every other day, according to the condition of the stools. Various drugs were tried after the initial dose of castor oil. The newer tannin preparations were used in about 50 cases. There are four that may be relied on as of use in this condition, they are, calomel, castor oil, bismuth and opium. The two first were given in every case, and in 26 they were the only ones given. Calomel is preferred in cases where there is vomiting or a tendency thereto and when the case is not particularly urgent 1/20 to 1/10 of a grain at hour intervals. Castor oil is given in all septic cases with infrequent stools and without stomach involvement, in which a prompt washing out of the small intestine is desired. Bismuth was given in 432 cases and frequently large doses, not less than 10 grs. every one or two waking hours regardless of the age of the patient. To be of service it must produce black stools, that is, to be converted into sulphide in the intestine. If it passes through the bowel unchanged, sulphur should be supplied in the form of precipitate of sulphur, a 1-gr. powder given with each dose of bismuth. Opium is indicated if there is pain, tenesmus and frequent stools, and he has found it necessary to use it in 200 of his cases. Four or five passages a day are required to maintain drainage. But when the case is one of intestinal infection with infrequent foul stools or no stools at all, active laxatives are the only medication. Many children die because of the physician's idea that the diarrhea must be stopped. Kerley is not in favor of too frequent bowel irrigation as it may produce injury, straining, distension, etc. He usually employs a normal salt solution, luke warm, if there is high fever. Where there is blood in the stools he has used tannic acid, though he doubts its special value. The method he employs is the soft rubber catheter, No. 14, English, attached to a fountain syringe, the bag of which is held three or four feet above the child's body. When the catheter has been introduced about two inches the water is allowed to pass in slowly, filling the colon. This in a child eighteen months of age will require twenty-four to thirty ounces of water. When this or a lesser amount, at least one pint, has passed in, it is allowed to run in and out at the same time. The general management of the child is important; instruction should be given as to the care of bottle and nipple. He thinks that dispensaries do excellent work in instructing mothers how to care for their children. The municipalities should establish milk laboratories and ice stations for the poor, where these necessities may be obtained free or at a very small cost.

50. **Scarlatina.**—One of the graver dangers of scarlatina is in the invasion of the mucosa of the nasopharynx by bacilli causing scarlatinal sore throat, viz., streptococci. Seibert uses for this condition a prescription composed of tincture of iodin, 2 grams; potassium iodid, 1 gram; distilled water, 120 grams; carbolic acid, 10 drops. A teaspoonful of this mixture is administered every hour. An experience of twenty years has failed to show any carbolic intoxication with this mixture. Mild iodism and slight gastric pains may temporarily be produced. To clean and disinfect the infiltrated mucosa he employs irrigation with 1 to 5 per cent. warm solution of ichthyol repeated every six hours where the infiltration begins to obstruct the passageway between the nares. Where these are insufficient, more vigorous measures are required. During the past year he has treated six cases with local applications of 50 per cent. resorcin solution in alcohol, which he has also employed for the last eight years for the treatment of post-nasal catarrh in infants and children. He reports a case of scarlatinal nasopharyngitis treated with this prescription. He considers it imperative to attempt to destroy the pathogenic bacteria in scarlatina whenever they come within our reach and these resorcin-alcohol applications have proven themselves harmless and are indicated, he considers, whenever the nasopharynx becomes involved.

56.—See abstract in THE JOURNAL, xxxvi, p. 128.

58. **Smallpox.**—Towne thinks that modern sanitation has mitigated this disease, and it is not impossible but there may have been an acquired immunity through the vaccination of generations. The hesitancy with which the diagnosis has been made in this epidemic is due to various causes, inexperience with the disorder being one cause.

60.—See abstract in THE JOURNAL, xxxvi, p. 128.

62.—Ibid.

63. **Hemophilia Neonatorum.**—The nature of hemophilia has not been cleared up and Greef reviews the theories and findings in congenital cases. Three cases are reported, in two of which postmortems were made. He is inclined to believe that the condition rests upon abnormal permeability of the vascular walls. The large majority of children succumb and little can be done by treatment. He is inclined to think that many of the cases classed as meleua neonatorum were fatal cases of hemophilia.

65. **Hemorrhagic Disease of New-Born.**—Brown reports two cases of hemorrhagic disease of the new-born, the clinical history of which corresponds more exactly with the classified description of Buhl's disease. The ictero-cyanotic skin, extreme wasting, marked gastro-intestinal hemorrhage, eczema, absence of continuous temperature and time of occurrence make points of agreement. The treatment in case 1 was with gelatin tubes containing about 1 dram, heated and diluted and fed to the child with very marked perceptible effect. In the second case gelatin was used in another form and the hemorrhage rapidly decreased.

68. **Streptothrical Infection.**—Musser reports two cases of streptothrical infection, one which, although postmortem observation was lacking, was interesting as determining the

this result. The only explanation he offers is that the contraction of the tensor tympani, spasmodic in character, being overcome by the removal of the incus in one ear, the synergetic contraction of the tensor in the opposite ear induced by cross influence is also overcome by a beneficial cross influence emanating from the operation on the diseased ear. Several cases kept under observation are reported and the method of operation described. Since 1892 he has operated upon 53 cases of progressive hardness of hearing in order to break the retractive force of the tensor tympani, 41 times by incudectomy, 4 by resection of the long limb of the incus and 8 by tenotomy of the tensor tympani. Incudectomy he considers the preferable operation and proposes to present the results in a future communication.

29. **Meniere's Disease.**—The term Meniere's disease is criticized by Smith, who holds that, if it means anything, it must be restricted to that complexity of symptoms at present recognized as the outcome of what is termed apoplexy of the labyrinth and this must be primary and occur suddenly in patients previously free from ear trouble and enjoying excellent health at the time of the attack. Thus restricted, Meniere's disease is a most exceptional rarity, and if we exclude previous systemic disease as a causative factor, it must be regarded as the result of traumatism. The symptoms of Meniere's disease do not arise, as it seems to have been definitely shown, from a single disease of the labyrinth, but are more or less prominent in traumatisms and various other pathologic changes involving the ear and adjoining structures, and he asks would not the cause of otology be best served and confusion averted by adopting a nomenclature defining as far as possible the location of the various affections of the internal ear without the consideration of Meniere's disease. He thinks that in many instances, injuries to the brain substance proper are the cause of an inability to move in a forward direction. He offers the term tympanic vertigo as efficient and impressive, to distinguish between vertigo due to middle-ear disease and that involving other parts of the ear or neighboring structures.

30. **Malaria.**—The peculiar *x*-fever which follows malaria and is resistant to quinin in the South, is, according to Penn, best considered as post-malarial fever, a sequela of the estivo-autumnal form occurring in susceptible individuals or those whose condition is such as will permit the toxic effects of the germs to continue the fever after the germs have left the body. It is not, practically speaking, a malarial fever at all, nor is it a new fever, but it is a post-malarial fever. This accounts for the irregularity, the frequent mild type of the cases, and the time of their occurrence. He desires to call the attention of laboratory workers to this line of thought and suggests, if confirmed by investigation, the possibility of good effects from serum treatment or antitoxin in these cases.

31. **Syphilis.**—The skin complications of syphilis mentioned here by Engman are tuberculosis, epithelioma, blastomycetic infection, erysipelas, seborrhea, pyogenic infections, mixed chancre, trauma, and hemorrhagic syphilid. He also points out how iodin intoxication may be engrafted upon the syphilitic lesion.

37. **Post-Operative Sequels.**—It was the purpose of Oastler to obtain as far as possible the histories of post-operative sequels of about 200 cases of complete hysterectomy and double salpingo-oöphorectomy and 150 cases of more conservative operative procedures so as to compare the merits of the two. Of the 200 cases selected for the first series, the conditions were carcinomata, sarcomata, fibromata of the uterus, septic metritis, ovarian cyst, uterine rupture, pyosalpingeal abscess, tubercular salpingitis, hydrosalpinx and hematosalpinx and ectopic gestation. The methods employed, whether abdominal or vaginal, did not seem to make much difference. He finds that the symptoms of artificial menopause occur with more regularity and greater severity and are of longer duration than is generally supposed, some women being left invalids. The symptoms are dependent for the most part on removal of the ovaries rather than the uterus; therefore, after suprapubic hysterectomy, there is no indication for leaving the uterus. Also that many cases in which it has been customary to advise hysterectomy can be treated in future by more conservative methods, which have been mentioned, such as leaving the ovaries wherever possible, resecting cystic ovaries and implanting small portions of healthy ovary on the side of the uterus or broad ligament, resection of the tubes or seat of hydrosalpinx or hematosalpinx and draining pelvic exudates and cases of pyosalpinx by the vagina. These conservative methods do away with the artificial menopause, relieve symptoms, and allow patients to continue their sexual life with the possibility of pregnancy.

38.—See abstract in THE JOURNAL, xxxvi, p. 1650.

39. **Kraske Operation.**—Edebohls finds the Kraske operation objectionable; and recommends an operation consisting in removal of uterus, resection of cancerous bowel, and end-to-end anastomosis of the sigmoid and rectum, all performed at one sitting by anterior abdominal incision which he finds in every way superior. He claims its superiority over the Kraske procedure in cases of high carcinoma of the rectum in the following important particulars: "1. A preliminary colostomy and, in favorable cases, a secondary operation for the closure of the artificial anus becomes unnecessary. 2. Removal of the sacral glands and all affected tissues posterior to the rectum can be accomplished with greater facility and thoroughness. 3. The liver can be examined for secondary cancerous nodules immediately after opening the abdomen, and, if such nodules be found, the abdomen can be closed without inflicting further unnecessary operative injury upon the patient. The unavoidable conclusion to be drawn from the above premises is that the Kraske operation is never *justifiable in women.*"

41. **Sactosalpinx Hemorrhagica.**—Waldo reports two cases which he thinks demonstrate the fact that hemorrhagic accumulations in the tubes are not always due to ectopic gestation. They are carefully observed and reported and pathologic examinations made and appear to have been due to hemorrhage in the tube independent of any ectopic pregnancy.

43. **Ovarian Symptoms.**—The ovarian symptoms which are commonly attributed to inflammatory conditions are held by Atlee to be often due to other conditions than diseases of the ovaries themselves. He thinks certain other uterine pathologic conditions may cause symptoms most marked by pain referred to the ovaries and that in certain women whose health has deteriorated, though showing no pathologic condition beyond anemia of mild grade, symptoms referable to the ovaries are not infrequent. In women with neuralgic dyscrasia, if neuralgia develops in the lumbo-abdominal distribution, very confusing symptoms may arise, and in cases of oxyluria, symptoms referable to renal, ureteral or vesical dilatation may simulate or lead to a diagnosis of ovarian disease. Besides this we have two great neuroses, neurasthenia and hysteria, giving rise to symptoms simulating disease from pure pathologic conditions. The treatment is the correction of the morbid conditions giving rise to them and with a better diagnosis and understanding of these cases we find the indications for spaying narrowing themselves down to a very small figure as compared with those of the past decade.

47.—See abstract in THE JOURNAL, xxxvi, p. 1727.

48. **Summer Diarrhea of Children.**—An analysis of 555 cases of summer diarrhea was made at the out-patient department of the Babies' Hospital in New York during the months of June, July, August and September, 1900. The cases were all from the tenement population, the majority were under twelve months of age, and only 51 were over 2 years. About 14.5 per cent. were breast-fed, out of those under six months of age, and 10 per cent. between the ages of six and twelve months, though some allowance must be made for mothers' statements in this regard, as there are very few tenement breast-fed infants who are not given milk, soups, tea, etc. The larger proportion were fed on cow's milk diet wholly or in part. Very few took proprietary

foods. One hundred and fifty-seven cases were of twenty-four hours' duration before first seen; 197 had been ill from two to five days, and 76 from five to ten days; 111 had had diarrhea over ten days, and 11 had been ill for two weeks. With some there was simply so-called dyspeptic diarrhea with moderate fever and slight prostration, others had been ill for several days with high fever and were in a critical condition. Nearly one-half recovered within a week. Quite a number lingered along until the fourth or fifth week and some for several months. In 56 the treatment was not continued. Out of 449 treated to the conclusion of their illness, 10 died, the death-rate being a little over 2 per cent. There was one invariable rule of treatment and that was to stop the milk at once. It would be impossible to the great mass of physicians to differentiate bacteriologically the nature of the infection in a large proportion of cases; this has been impressed upon him by considerable autopsy experience. We learn that every case of summer diarrhea must be looked on as dangerous and treated vigorously whether the initial symptoms are mild or severe. He doubts whether, in the majority of cases, the streptococcus or colon bacillus play a very important part. The average case is of gradual onset. If the milk is discontinued, a substitute must be found and the one he finds most useful is cereal water, usually barley water, and where this does not answer, rice water. The directions are: Robinson's baked barley flour, two tablespoonfuls, water one pint, boil for twenty minutes, strain and add water to make one pint when the cooking is completed. Rice is similarly treated. Brandy and whiskey should never be given to children with summer diarrhea, as the dangers of nephritis and stomach involvement are enough without provoking them with liquors. Animal broths should not be added to the diet in too large amounts on account of their laxative effects, but he uses them moderately and with care. Brandy and egg water mixture, so popular with many, is an atrocious milk substitute. Dextrinized gruels have a useful field in summer diarrheas, the dextrinization being of value as it offers more concentrated nourishment. Care should be taken that the cereal water is not at a higher temperature than 100 F. The substitute diet should be allowed to be given at two-hour intervals, if the child will take and retain it in good quantities. Boiled water may be given at any time. The patient should be kept in the largest room, and if there is fever, sponged in cold water for fifteen minutes several times a day. The milk diet is resumed gradually, diluting the barley water, with slight increase every day or every other day, according to the condition of the stools. Various drugs were tried after the initial dose of castor oil. The newer tannin preparations were used in about 50 cases. There are four that may be relied on as of use in this condition, they are, calomel, castor oil, bismuth and opium. The two first were given in every case, and in 26 they were the only ones given. Calomel is preferred in cases where there is vomiting or a tendency thereto and when the case is not particularly urgent 1/20 to 1/10 of a grain at hour intervals. Castor oil is given in all septic cases with infrequent stools and without stomach involvement, in which a prompt washing out of the small intestine is desired. Bismuth was given in 432 cases and frequently large doses, not less than 10 grs. every one or two waking hours regardless of the age of the patient. To be of service it must produce black stools, that is, to be converted into sulphide in the intestine. If it passes through the bowel unchanged, sulphur should be supplied in the form of precipitate of sulphur, a 1-gr. powder given with each dose of bismuth. Opium is indicated if there is pain, tenesmus and frequent stools, and he has found it necessary to use it in 200 of his cases. Four or five passages a day are required to maintain drainage. But when the case is one of intestinal infection with infrequent foul stools or no stools at all, active laxatives are the only medication. Many children die because of the physician's idea that the diarrhea must be stopped. Kerley is not in favor of too frequent bowel irrigation as it may produce injury, straining, distension, etc. He usually employs a normal salt solution, luke warm, if there is high fever. Where there is blood in the stools he has used tannic acid, though he doubts its special value. The method he employs is the soft rubber catheter, No. 14, English, attached to a fountain syringe, the bag of which is held three or four feet above the child's body. When the catheter has been introduced about two inches the water is allowed to pass in slowly, filling the colon. This in a child eighteen months of age will require twenty-four to thirty ounces of water. When this or a lesser amount, at least one pint, has passed in, it is allowed to run in and out at the same time. The general management of the child is important; instruction should be given as to the care of bottle and nipple. He thinks that dispensaries do excellent work in instructing mothers how to care for their children. The municipalities should establish milk laboratories and ice stations for the poor, where these necessities may be obtained free or at a very small cost.

50. **Scarlatina.**—One of the graver dangers of scarlatina is in the invasion of the mucosa of the nasopharynx by bacilli causing scarlatinal sore throat, viz., streptococci. Seibert uses for this condition a prescription composed of tincture of iodin, 2 grams; potassium iodid, 1 gram; distilled water, 120 grams; carbolic acid, 10 drops. A teaspoonful of this mixture is administered every hour. An experience of twenty years has failed to show any carbolic intoxication with this mixture. Mild iodism and slight gastric pains may temporarily be produced. To clean and disinfect the infiltrated mucosa he employs irrigation with 1 to 5 per cent. warm solution of ichthyol repeated every six hours where the infiltration begins to obstruct the passageway between the nares. Where these are insufficient, more vigorous measures are required. During the past year he has treated six cases with local applications of 50 per cent. resorcin solution in alcohol, which he has also employed for the last eight years for the treatment of post-nasal catarrh in infants and children. He reports a case of scarlatinal nasopharyngitis treated with this prescription. He considers it imperative to attempt to destroy the pathogenic bacteria in scarlatina whenever they come within our reach and these resorcin-alcohol applications have proven themselves harmless and are indicated, he considers, whenever the nasopharynx becomes involved.

58. **Smallpox.**—Towne thinks that modern sanitation has mitigated this disease, and it is not impossible but there may have been an acquired immunity through the vaccination of generations. The hesitancy with which the diagnosis has been made in this epidemic is due to various causes, inexperience with the disorder being one cause.

60.—See abstract in The Journal, xxxvi, p. 128.

62.—Ibid.

63. **Hemophilia Neonatorum.**—The nature of hemophilia has not been cleared up and Greef reviews the theories and findings in congenital cases. Three cases are reported, in two of which postmortems were made. He is inclined to believe that the condition rests upon abnormal permeability of the vascular walls. The large majority of children succumb and little can be done by treatment. He is inclined to think that many of the cases classed as melena neonatorum were fatal cases of hemophilia.

65. **Hemorrhagic Disease of New-Born.**—Brown reports two cases of hemorrhagic disease of the new-born, the clinical history of which corresponds more exactly with the classified description of Buhl's disease. The ictero-cyanotic skin, extreme wasting, marked gastro-intestinal hemorrhage, eczema, absence of continuous temperature and time of occurrence make points of agreement. The treatment in case 1 was with gelatin tubes containing about 1 dram, heated and diluted and fed to the child with very marked perceptible effect. In the second case gelatin was used in another form and the hemorrhage rapidly decreased.

68. **Streptothrical Infection.**—Musser reports two cases of streptothrical infection, one which, although postmortem observation was lacking, was interesting as determining the

possibility of recognizing the more or less obscure conditions met with in pulmonary streptothrical infection and the other as showing the doubtful symptoms and rapid course of localized cerebral infection by these organisms. He closes his paper with the following conclusions: "1. That the streptothrix in some varieties is pathogenic to man and gives rise to inflammatory, suppurative and necrotic lesions in the lungs and the skin, and by metastasis, probably in the brain and spinal cord and rarely, other organs (the kidneys). 2. That, while this pathogenicity is more than likely, and is primary, yet it must be remembered, it may be a secondary growth in the course of other infections. 3. That, in the pulmonary cases especially, death is due to a mixed infection. 4. That so-called sterile abscesses may be instances of streptothrical infections. 5. That afebrile processes may be due to this infection, or, conversely, this affection may be unattended by fever. 6. That the morphological relations to tubercle bacilli and allied organisms must be remembered. 7. That clinical observation and laboratory studies have yet to determine the clinical course of the streptothrical infections and their relationship to other streptothricæ on the one hand, and to tuberculosis on the other. They are not unlike other streptothrical infections, if these clinical facts are true, in that in actinomycosis, for instance, we find frequently a chronic afebrile course." He says these questions are as yet *sub judice* and require laboratory investigation and future clinical observation. As a suggestion of the nature of the infection, the question of leucocytosis should be looked into.

69.—This article has appeared elsewhere. See The Journal, xxxvi, paragraph 49, p. 1894.

73.—Ibid., paragraph 25, p. 1738.

77. **Commitment of the Insane.**—Fletcher criticises severely the old and new laws regarding the commitment of the insane in Indiana, maintaining that they are lacking in proper securities to those charged as being insane and in many respects take the form of secret inquisition. He does not believe that many non-insane persons are detained in public asylums. He thinks it impossible with the officers of these institutions, but it is perfectly possible under the Indiana law for persons to be picked up without chance for defense and committed as insane.

80. **Feather Beds and Colds.**—Hessler considers the use of feather-beds and the dusty condition developing after their long use, responsible for many of the irritations of the respiratory tract. The same objection applies to curtains, carpets and tapestry that collect dust and he particularly mentions the German fashion of using feather beds as objectionable.

86.—This article has appeared elsewhere. See The Journal, xxxvi, title 142, p. 1736.

87.—Ibid., July 27, paragraph 63, p. 287.

89. **Advancement.**—This term is defined by Valk as the bringing forward the insertion of the tendon of one of the straight muscles of the eye, from its normal position of attachment to the eye-ball to another in the same plane, but nearer to the cornea, but he includes also the shortening of the muscle plane at its insertion into the sclera. He discusses the different operations and describes the one which he has found most advantageous, which he credits to Savage, though he himself worked simultaneously in developing it. The operation as he performs it in latent, fixed or paretic squint, is described as follows: "After the eye has been properly prepared with a solution of boracic acid and a solution of cocain used or an anesthetic if necessary, the lids are separated by a speculum and the conjunctiva raised with the forceps over the lower or upper point of the insertion of the tendon. I then make a vertical incision followed by one horizontal, forming an L. This is dissected loose from the underlying tissue and then an opening is made in Tenon's capsule and the small hook is passed beneath the tendon, as the point of the hook comes out another hook is inserted in an opposite direction and the two hooks forcibly drawn apart, so exposing the tendon and part of the muscle. I now pass the small instrument, called twin strabismus hook, beneath the muscle and the hooks are allowed to separate by the action of the small spring in the joint and the two hooks are then removed. We now have the muscle and the tendon fully exposed and ready for the suture. Now, taking a piece of sterilized catgut from the capsule, we thread the needle and pass it first through the lower part of the tendon, then through the muscle, as far backward as we wish to make the 'tuck,' passing from within outward. It then goes across the belly of the muscle and is passed through, from without inward and back to the tendon where it passed from within outward, at a point corresponding to the first insertion. As the ends are tied over the tendon at this fixed point, we see readily the 'tuck' formed as the muscle belly is drawn forward and its long axis shortened. However, in case of fixed squint, I do a complete tenotomy of the opposing muscle before the suture is tied." The question when this operation is indicated seems to him the most important. He has no confidence in any method of examining that will "take the higher centers off their guard," or destroy the fusion force or guiding sensation of the eye and he uses the tests that destroy it simply as confirmatory. He asks, do not physiologic conditions show that Nature intended the eye should have power to move the eyeballs more in one direction than others, that the interni should be the most powerful—even independent of the power of convergence—and next, the externi, and in following order the inferior and the superior, the weakest of all. Should we not find, he asks, that the power of adduction is two to four times greater than that of abduction, and the power to turn the eyes downward somewhat greater than that of sursumduction, and, therefore, he fixes his standard as that in which the power of abduction is more or less one of fixed condition under which the eyes will diverge 6 or 8 prism degrees, so as to fuse or blend the retinal images, and then we can expect to find the power of abduction anywhere from 12 to 30 prism degrees without any muscular imbalance. Similarly we find the sursumduction one, two or three degrees in each eye and the opposing muscle will show deorsumduction of about one degree greater. With this condition of the muscular balance fully confirmed by several tests, he does not think we can have any muscular imbalance, without regard to what the other tests may develop when deprived of the fusion force. In defining noticeable modifications from that standard for his indications for operation, he points out the indications in various conditions, esophoria, exophoria, diplopia, convergent squint, etc. From his past experiences with the operation of advancement and shortening the indications depend upon one of degree, in reference to the change in position of the visual line; the power of the weak muscle, and that of imbalance of the muscle apparatus, as shown by the tropometer and tests of duction of prisms. He considers that advancement is fully required when we have a deviation of the visual line of more than thirty degrees of the arc. He concludes "That shortening is indicated in all cases of squint, if not too great, less than thirty degrees, combined with tenotomy, of the opposing muscle if necessary. That in all cases of imbalance—without any deviation of the visual line—the operation of shortening the weak muscle, thereby improving its power to turn the eye under the stimulation of the fusion force, is the best in my hands, as I have fully proved its application and usefulness. That the operation of shortening is also indicated in cases of paresis and the so-called paresis of divergence, in which we have a latent insufficiency of the muscular power, that frequently becomes manifest when they are about 40 years of age and presbyopia with hyperopia is present. That in all cases of heterophoria or latent squint, either lateral or vertical, the best results will always be obtained by the operation of shortening, without any fear of an over-correction, as long as the guiding sensation of the eye is free to act on the cerebral centers, as the process of healing takes place."

90. **Chalazion.**—Hale defines chalazion as tumor of the lid involving the Meibomian gland with obliteration of the glandular elements; limited by a surrounding membrane in which are found the perverted secretion of the earlier gland, glandular debris, micro-organisms and sometimes pus. He

thinks that the general health has much to do with its formation, some disorders producing a thickened secretion, and that the constant rubbing of the exposed lid, aided perhaps by germ infection, starts the inflammation which leads to chalazion. The only thorough treatment of this condition is excision in some cases, followed by the curette. Operation through the conjunctiva is more often called for in chalazion of the lower lid where the tarsus is thinner and the conjunctiva less intimately attached. In the upper lid the usual choice is excision through the skin of the lid.

100. **Smallpox.**—The epidemic of smallpox, the diagnosis of which is questioned by some in Clarksville, Tenn., is reported by Runyon, who calls attention particularly to the failure of glycerinated vaccin lymph in these cases. He does not know where the fault lies in the substance used. It may possibly have been in the original stock, or possibly from some other cause, but he would not risk the protective power of any glycerinated virus until he had followed it up with a point to make sure the subject had been rendered thoroughly immune to vaccination.

108.—See abstract in The Journal of July 13, p. 138.

109.—Ibid., p. 137.

111. **Pyemia.**—The cases of septic pyemia occurring early this year in Colorado and reported by Hall suggest bubonic plague in some of their symptoms and are of interest on that account. He has collected together 14 cases, 2 of which occurred in Chinamen and in connection with the existence of plague in California at the time caused some uneasiness. The occurrence of so many isolated cases of septico-pyemia within a few weeks in adults of previous good health was certainly unusual. His own opinion as to their existence is that many originated, as some certainly did, from a streptococcic sore throat, possibly not severe enough to attract much attention. He refers also to 2 cases of pneumonia accompanied with sepsis, which were fatal. The majority of the patients with abscess recovered; in many there was no bacterial examination made. In a few where they were made, a pure streptococcus infection was found.

116. **Nose and Throat in Chest Diseases.**—The object of Scheppegrell's paper is to emphasize the fact that the abnormalities of nasal respiration is due to partial or total destruction, atrophy, or other disease of the nasal cavities, may develop irritation of the lower respiratory organs. Therefore, in treating diseases of the chest, the possibility of irritation due to disturbance of the upper respiratory passages should not be overlooked, and no case of bronchitis or asthma should be considered incurable unless the nose and throat have been examined and abnormal conditions corrected, if possible. Often this examination, if made at all, is delayed until secondary changes have taken place, making cure no longer possible, but still some relief may be hoped for under proper management.

118. **Chloroform and Nitrite of Amyl.**—McIlhenny, on Senn's suggestion, started the use of nitrite of amyl, 1 dram, to a pound of chloroform in anesthesia, and the result was excellent. Nitrite of amyl acts as a decided check-rein to the chloroform, especially as to its effect on the circulation and respiration. It seems to modify the ill effects without interfering with its anesthetic properties. The stage of stimulation is much modified, the face does not become flushed, breathing is not labored or rapid, the stage of depression is often absent, the heart beats regular and strong. The pupils will be very misleading to a person giving nitrite of amyl with chloroform for the first time, for it requires very close attention to notice their response to light. Vomiting is very rare. The patient usually recovers consciousness very rapidly and there is no headache or fulness of the head as might be expected. The urinary secretion is increased, but contains no sugar or albumin. The body temperature is somewhat lower. From his experience he would greatly prefer this combination to chloroform alone.

129. **Uncinariosis.**—This term, which is applied by Stiles to the condition called anklostomiasis, is described as it occurs in man. A case is reported, showing that it exists in Virginia and he also had cases sent to him for confirmatory diagnosis from Ohio and the Rocky Mountain region, in which the condition was simulated by plant fibers. There is only one way in which it can be positively diagnosed, viz., by examination of the feces, but in this way its recognition is easy, and no special technique is necessary. The use of a moderately high power microscope will show eggs, though we must be careful not to mistake the eggs of ascaris for those of uncinaria, or those of oxyuris. The ascaris eggs have a thick gelatinous, often mammillated, covering and those of oxyuris have a thick asymmetrical shell, one side being almost straight. The whip-worm type, trichocephalus, possesses a smooth thick shell apparently perforated at each pole, and unsegmented protoplasm. The eggs of uncinaria are elongated ovals with thin shell and protoplasm either unsegmented or in the early stages of segmentation. Gross examination of the feces where the microscope is impracticable can be made by washing the stools thoroughly in a bucket and examining the sediment for worms about an inch long, about as thick as a hairpin or hatpin, with one end curved back to form a hook. The most commonly used drugs for treatment are thymol and male fern. The stools should be disinfected with quicklime. He describes the life history of the parasite, its zoological characteristics, the means in which it injures by biting the intestinal walls and also gives the different species found in different animals, the uncinaria duodenalis being the human parasite.

Plague and Its Prevention as a Disease Communicable from Animal to Man. David Samuel Davies.—The published articles on plague were barren of interest to the epidemiologist, according to Davies, until Cantlie suggested that the endemicity of the disorder in certain ports of Central Asia, as it coincided with the distribution of a particular subfamily of rats, was possibly in causal relation with a definite rat habitat. Evidence rapidly accumulated, ultimately culminating in our present knowledge that plague is primarily an epizootic disease communicable to man rather than an epidemic disease communicable to animals. The records of the Sydney outbreak of plague may be taken as a typical manifestation of the introduction of plague epizootic amongst a wholly civilized white population. The following facts stand forth: "1. The disease did not spread by person-to-person infection. 2. The observed facts as to its spread can only be satisfactorily explained by assuming an animated host, not human, to diffuse the infection in place, and a second host to communicate the infection to man; the two hosts are the rat and the flea. 3. 'Contact' in regard to plague infection does not necessarily mean one who has lately been associated with a plague patient; it means rather one who has been exposed in more or less close association with plague rats within five days. 4. Nearly all the cases were bubonic in type, a type very little infectious. 5. The outbreak originated in connection with a wharf, almost certainly through the handling of plague rats from infected ports; and the history of further infection in the town pointed definitely to the same means of distribution." Davies remarks that the importance of rats need hardly be questioned or dilated upon in the spread of plague. He asks, are our present regulations sufficient to prevent the introduction of plague, or, in other words, are the means accurately adapted to its etiology? It is a great blunder to treat pestilence uniformly. The present local government regulations in England against cholera, yellow fever and plague are practically transcripts of the former regulations against cholera, to the circumstances of which purely human disease they are excellently adapted. Up to the spring of 1901 no further official instructions regarding plague were issued. He calls attention to the fact that the port of Bristol found itself in a peculiar position in the beginning of the present year. A grain vessel arrived from an infected port with no history of illness, and, therefore, not infected under the regulations or liable to any detention or supervision. For some months special precautions as to offmooring of vessels from the quayside, disc-guarding of ropes, up-lifting of gangways, and day and night watchmen had been enforced as stringently as the absence of special powers would permit, and careful watch was kept. Thirteen dead rats were found in the forehold and plague as the cause of death certified, but not until the cargo had been partly discharged and distributed. The ship was dealt with as an infected ship and 226 rats were destroyed. He says to bring infected rats to a port in unlimited numbers and then rely on attempts to prevent them coming ashore is obviously taking the evil at the wrong end. It is impossible to destroy all rats on a loaded ship, while it is not difficult to practically do this in an empty one. The best policy, therefore, is to secure rat-free merchant ships, and the author asks: Is this practicable? Dr. Ashburton Thompson suggests that if vessels which engage in coasting voyages, lasting three weeks to a month, are fumigated at the point of departure before loading and at the ultimate ports touched on the voyage, few if any rats are discovered to remain, and this statement applies to steam vessels of various tonnages up to 4000. This method has been carried out, he says, under intercolonial agreement requiring a vessel to produce a certificate of fumigation, without which they are subject to detention. The method, therefore, is practicable. Davies says it is high time our knowledge of the etiology of plague be utilized in international as well as in other traffic and the rats must be destroyed before loading the ship.

The Lancet, August 10.

Mortality from Phthisis and Tuberculous Diseases Considered in Some Aspects Which May Be Demonstrated by Means of Life Tables. T. E. HAYWARD.—The author publishes and discusses tables showing the total expectancy of life under various aspects, and the difference produced by excluding phthisis as a cause of mortality. He also gives tables showing the total life capital of England and Wales for the middle of the year 1891, and to what extent this life capital would have been increased by, 1, eliminating phthisis, and 2, by doing away with all other tuberculous disease as a cause of mortality. He finds that the average period of working life would be lengthened on the average by very nearly two years. The years of human life are now capable of being translated into terms of money; it is evident that the ravages of phthisis may entail a very serious financial loss to the community. He admits that this work is not that of a physician, but he leaves it to the actuaries to measure this and suggests to those concerned in the management of industrial and other life assurance societies that it might be an act of profit to them to subscribe something toward the establishment and management of sanatoriums for the treatment of phthisis.

On the Physiologic Cure of the Morphia Habit. W. OSCAR JENNINGS.—The author claims that before the publication of his little work in 1890 there existed no treatment of the morphin craving founded on therapeutic indications. His first observations were made in his own case and he has had opportunity of verifying these during the last ten years. He remarks that there are many persons who lack the will power to carry out the treatment alone. There are others who want to get well and have no real craving that prevents them, but are suffering from hysteric neuro-mimetic craving. In these cases great tact is necessary. Such patients should never know how much morphin they are taking or what other agents are being administered. The symptoms, though really distressing, are entirely ideal. If a patient is seriously desirous of giving up, he should commence by renouncing all liberty of action during the treatment, give up his syringe and his solution and be guarded against all temptation. When the morphin is associated with some other addiction, the first thing is to suppress the other stimulant, whatever it may be. This is not difficult if it be alcohol or cocain. The quantity of morphin taken becomes more satisfactory instead of being antidoted, as it were, by the other stimulant when they were taken together. Jennings believes in the gradual reduction as slowly as is necessary to effect a cure without distress. It is desirable first to bring about a change as soon as possible in the mode of administration of the drug. If this can be effected early, so much the better; but there should be a gradual substitution of the rectal for the hypodermic injection the moment the patient is reduced to 2 grains by the skin. Two grains would seem to be the vital requirement; above 2 grains morphin can be found in the urine; below this it seems to be assimilated. From this point onward twice as much should be given by the rectum as by the skin. The great point is to get rid of the syringe, to wean the patient from his accustomed stimulant. Moreover, an injection by the rectum is not agreeable and has not the fascination that leads to the constant use of the syringe. The patient is satisfied with what is really required to prevent discomfort. In giving morphin it should be remembered that this is not a sedative but a stimulant, the withdrawal of which causes a suppression of vital force and gives rise to general functional disturbance greater than would result from the privation of other stimulants. The utility of heart tonics is evident. The next great factor of craving is hyperacidity of the stomach and organs generally. This suggests the administration of bicarbonate of soda, a method to which he has been calling attention for thirteen years and the importance of which is now recognized by every writer. Bicarbonate relieves craving so far as it is caused by over-acidity in the same way that heart tonics relieve it when caused by cardiac sluggishness and nothing more. Other means of relief may be supplied as indicated, but the third of his therapeutic triad is the hot-air bath. The effect of the bath is largely due to its tonic and sedative action, but it may also act as an eliminator of some excitant of craving. This may possibly be the oxi-di-morphin which is formed in the body and is considered by Marmé as its chief cause. He insists on the non-alcoholic régime. There must be no reading in bed during the progressive reduction. For insomnia, cerebral galvanization is sometimes magical, but if unsuccessful the best hypnotic is trional. The fluid extract of coca and kola are frequently of use and the only other drug taken constantly by his patients is valerianate of ammonia. He warns against the synthetic derivatives of morphia, such as dionin and heroin, which can get up a worse condition than morphin itself. The latter is only second to cocain as a drug to be avoided. It has been said that ex-morphin habitués are subject to periodical periods of craving, and these are more likely to occur in those who have undergone the slow reduction. These are errors. One of the best proofs of the progressive plan is that when properly carried out the patients gain in weight. One of the consequences of this, however, is a tendency to hyperchlorhydria and excessive uric acid, both of which are factors of craving. Besides this the ex-habitué is generally polydipsic and boulimic and does not restrain his appetite, drinks of alcoholics and eats in proportion. As he is easily tired, he has a disinclination to be active. He is nearly always saturated with uric acid and on the verge of bilious or gastric failure. This is the cause of what is called after-cravings. We must always remember that every morbid sensation during the past addiction having been treated with morphin, every malaise in the future will suggest it. The best proof that these are not real cravings is the result of treatment, for after being properly treated the cravings will disappear. When the ex-habitué is careful to lead an abstemious life he is not liable to such cravings. Everything should be done to keep up a healthy tone of the system, taking exercise as much as possible without fatigue; the regular use of Turkish baths is also specified. The remainder of his paper consists in an account of cases illustrating the different phases and forms of the condition and the results of special treatment.

Electrolytic Transmission of Sulphur Through Pig's Skin, and Its Therapeutic Value in Eczema, Gout, etc. FRANCIS WILLIAM SMITH.—Smith has experimented on pig's skin and found that sulphur can be driven through this substance from Harrogate sulphur water by electricity. The therapeutic value of this treatment is in its connection or use of the electric current with the baths. The fact that many cases of long-standing eczema have been benefited under the method would justify this treatment.

Bulletin de l'Academie de Med. (Paris), July 23.

Preparalytic Hemichorea. Boinet.—Bechtereff has recently published the case-report of a man of 68, suddenly seized with left hemichorea, subsequent to a violent emotion. He died fifteen days later with symptoms of paralysis of the heart. The autopsy disclosed a circumscribed hemorrhagic focus in the posterior portion of the optic layer. Boinet describes a case in which a sudden hemichorea appeared, followed by atrophy of the muscles of the left arm and leg, with corresponding facial asymmetry. In a second case, hemiathetosis and hemichorea coincided with the atrophy of the muscles, deviation of the tongue and facial asymmetry on the side affected. He has also witnessed a case of rhythmic hemichorea in a patient with general paralysis. He attributes this preparalytic or postparalytic hemi-athetosis or hemichorea to an interruption of the conductors connecting the central ganglia with the cerebellum—the route traversed including the superior peduncle of the cerebellum, the red nucleus, the optic layer, the internal capsule and the anterior portion of the lenticular nucleus.

Tuberculous Rheumatism. A. Poncet.—Three cases are described which presented the clinical picture of acute articular rheumatism. Bacteriologic investigation disclosed the tubercle bacillus, and inoculations of guinea-pigs confirmed the tuberculous nature of the arthritis. Poncet proposes the term "pseudo-rheumatism of bacillary origin" for the affection.

July 30.

Treatment of Chorea by Immobilization. Huyghe.—The method of treatment described is a sort of auto-suggestion, and has proved invariably successful in an extensive experience. The patient is given a little chloroform—not enough to anesthetize—the limbs are massaged vigorously and placed in splints, immobilizing them for five or six days. If the slightest choreic movements are noted after this interval, the treatment is recommenced. The patient is all the time under the influence of auto-suggestion. He no longer sees his limbs, and forgets to move them. The treatment is entirely harmless and can be applied to all varieties of cases and in all kinds of surroundings.

Latent Cardiopathy and Sudden Death. Kelsch.—Cases may occur anywhere, but they are best studied in the army in which all the factors, both of cause and aggravation, are magnified. Kelsch has collected thirty cases of these non-rheumatic cardiopathies, developing without symptoms, and revealed only at death, which is precipitated by some extra exertion or excitement. The original cause is some poisonous influence—in which alcohol takes the lead—or the results of infection—diphtheria, typhoid fever, la grippe or an eruptive disease—or the rudimentary lesion may be the result of intoxication from infectious products. Overexertion or excesses of any kind, start these latent rudimentary lesions into an evolution which progresses insidiously to the fatal termination.

Centralblatt f. Chirurgie (Leipsic), July 27.

Hints for Cystoscopy. S. Goldberg.—Olive oil is better than glycerin to lubricate the tip and angle of the cystoscope. Neither cocain nor chloroform are so effective for anesthetizing the bladder in certain cases as 50 c.c. of a 5 per cent. solution of antipyrin, left for ten to twenty minutes, and then washed out before the introduction of the cystoscope.

Extirpation of the Appendix Between Attacks. M. Jaffe.—In certain cases of appendicitis, the process may develop without much disturbance, but may leave adhesions, infiltrations and cicatricial formations from perforation of the appendix into the cecum, or a similar lesion. Instead of the vain search after the appendix in such cases, Jaffe recommends resection of the portion of the intestine involved, and in case of stenosis, enteroanastomosis.

Deutsche Med. Wochenschrift (Berlin and Leipsic), July 25.

Therapeutic Application of External Palpation of the Rectum. W. Ebstein.—Palpation of the rectum through the gluteal groove almost invariably reveals that it is filled with accumulated fecal matters. By massaging from above downward it is possible to expel these contents, and the massage strengthens the muscular action of the rectal walls. The massage can be done by the individual himself, and will be found a useful therapeutic measure in case of stagnation and torpid muscles.

Multiple Hemorrhages of Face and Conjunctivae. Hoppe.—A sudden pressure on the thorax has been known to induce multiple hemorrhages in the face and conjunctivæ. The phenomenon was consecutive to trauma in the nine cases on record, but Hoppe observed a case in which it followed violent retching. The patient, a man of 35, had eaten mushrooms and fearing that they were poisonous, tried to vomit them by tickling his throat and retching. All the cases were distinguished by the swollen cyanotic aspect of the face, and the numerous hemorrhages, mostly petechial, with transient disturbance of sight.

August 1 and 8.

Acromegalia. A. Fraenkel.—Four cases of acromegalia are described with the postmortem findings. Nothing was found peculiar to the disease in any organ, except a tumor in the hypophysis in each case. The tissue of the tumor showed alveoles with granulated cells and free vascular ramifications, evidently derived from the epithelial elements of the anterior lobe. In one case, the cells were almost exclusively free from granulations, with many polynuclear and round cells. The posterior lobe of the hypophysis was intact in all four cases. The hereditary character of acromegalia was evident in one case. One was not the complete type of acromegalia, but seemed rather a transition between this and gigantism.

Disturbances in Heart Action Not Due to Organic Troubles. T. Rumpf.—Several cases have come under Rumpf's observation, of disturbances in heart action noticed after considerable loss in weight from a course of treatment for obesity. He gives illustrations of the most severe case of this kind, showing that the apex changed its position by 13 cm., according as the young man lay on the right or left side or stood erect. The loss of the fat in the abdominal cavity after the weight had dropped from 238 to 153 pounds, evidently caused the previously stretched diaphragm to sag, and this allowed the displacement of the heart. The symptoms indicated cardiac insufficiency, but Rumpf advised the patient to cultivate his former obesity, which he did, with the complete disappearance of the heart disturbances, as confirmed by an examination thirteen years later. Rumpf has also observed two cases, simulating cardiac insufficiency in the symptoms after a hearty meal, or after eating certain foods, but vanishing as the stomach became empty. The troubles are due in such cases to the mechanical interference with the heart's action by the diaphragm distended by gases in the stomach. The cases described were observed for twelve years and no signs of cardiac insufficiency beyond the functional disturbances have developed. The heart disturbances may be of a reflex nature. The pulse may be accelerated, irregular or interrupted, or may show a second systole with no complete diastole. He calls attention to the variations in the heart action after eating and warm baths, observing that this physiologic variation is sometimes accepted as the result of treatment at a health-resort.

Muenchener Med. Wochenschrift, August 6.

Further Research on the Globulites. H. Buchner.—The results of further study of the globulites described in The Journal of August 17, p. 480, show that they are composed of barium sulphate. The barium is evidently derived from the peptone, while the sulphate is a product of the leucocytes themselves. The tests also demonstrated that any albumin or albuminoid substance from one species of animal attracts the leucocytes in another species with a specific

"Lockreiz," that is, acts as a stimulus to their local accumulation.

Injuries of the Vessels of the Root of the Mesentery. Wilms.—On the basis of two clinical cases and experimental tests, Wilms asserts that the superior mesenteric vein can be ligated below the pancreas without resulting gangrene of the intestine. It is dangerous to ligate it above the pancreas, where it merges into the portal vein.

Duplicity of Protopathic, Malignant Tumors. R. L. Gruenfeld.—Eight cases of the simultaneous occurrence of two varieties of malignant neoplasms are reviewed and a case personally observed is described. In Becker's case a melanosarcoma of the cheek and cancroid of the eye and ear appeared after extirpation of a rodent ulcer on the nose. In Niebergall's case a carcinoma, a fibro-sarcoma, a myoma and some polypi were found in one uterus. In Kretz's, an endothelioma of the dura mater coincided with a carcinoma of the esophagus. Other cases were those of a lipomyo-sarcoma in each kidney, associated with a psammoma in the brain and a carcinoma in the stomach; a carcinoma in the pancreas with multiple angio-sarcomata in the liver, and a case of roundcelled sarcoma and diffuse adeno-carcinomatous proliferation in the same uterus. There are nearly a dozen cases on record of double carcinomata or other malignant tumor, including Albert's case in which both breasts were the seat of primary carcinomata; Carriere's with symmetrical epithelioma in each kidney, and Bucher's with a primary carcinoma in the right breast, six years after the extirpation of a similar tumor in the left. In the new case reported by Gruenfeld, a diffuse, infiltrating carcinoma of the rectum coexisted with an endothelioma originating in the posterior lobe of the hypophysis cerebri or in the adjacent dura mater—it was impossible to determine which. No clinical symptoms had been observed during life suggesting acromegalia or other probable consequences of a tumor in the hypophysis. Heusser has described a somewhat similar case in which a carcinoma of the rectum coincided with an undiagnosed lymphosarcoma in the hypophysis. Köhler found 8 sarcomata among 37 cases of tumor of the hypophysis, but none resembling an endothelioma.

Treatment of Motor Aphasia. Vidal.—There are few fields more promising than the treatment of motor aphasia, especially when the memory is retained. The chief point in treatment is exercising the patient in the pronunciation of the words or syllables in which he is defective. It is important to study first, the sounds which he finds most difficult to pronounce. In one case it is the vowels, in another the labials, and so on. He must be trained to watch the lips of the speaker, and to watch his own lips with a hand glass. Gutzmann recommends teaching the patients to write with the left hand, as a means of educating a new, right speech center. Vidal, however, considers this too much of an effort for a patient past youth. The chief difficulty he has encountered in curing motor aphasia, is that occasionally mental effort causes headache, on account of the preceding apoplexy.

Wiener Klin. Wochenschrift, August 1.

Elimination of Chloroform from the Respiratory Organs. K. Buedinger.—In the tests reported in this communication, the elimination of chloroform continued for several days after the anesthesia. The chloroform clings to the sputa for days, and consequently its irritating effect is not restricted to the time of the narcosis, but persists long after. In persons with much mucous secretions, the chloroform is eliminated less rapidly, as it evidently combines with the phlegm and this may be a factor in the nausea and vomiting. It is evident that the removal of all accessible mucous secretions is indicated in all cases of protracted chloroform narcosis.

New Points in Skiagraphy. G. Kaiser.—The rays are collected in a lead funnel which thus concentrates their action on the spot desired. Kaiser also states that he uses tubes made of red or blue glass, and finds that no symptoms of irritation have followed, no matter how long the exposure or how intense the light, since he began using these colored tubes.

Klinitchesky Journal (Moscow), May.

Clinical Significance of Myoidema in Cerebral Affections. Hannouchkine.—In 84.8 per cent. of 355 cases of various cerebral affections examined at Moscow, myoidema was noted, pronounced in 73.8 per cent. and slight in 11. It is not pathognomonic of any special disease, as it was encountered in 57 to 100 per cent. of the 22 different kinds of cerebral affections investigated—constantly in the 11 cases of epilepsy and 11 of delirium tremens.

June.

Anatomy of Atrophy of the Intestines. P. Kusskow.—Examination of the intestines in infant cadavers, rabbits and kittens, has convinced Kusskow that others have been mistaken in their descriptions of some of the alterations noted in atrophy of the intestines in nurslings. The anatomic picture that Nothnagel and others have described is, in reality, merely the effect of putrefactive processes, chiefly due to distension of the intestines. No reliability can be placed on signs of atrophy except in undistended portions of fresh intestines. In the distended portions, the alterations can be attributed to atrophy only in the absence of destructive processes from distension and in case the lesser number of glands and orifices of the follicles fails to correspond with the extra thinness of the tense mucous membrane.

Vratch (St. Petersburg), June 1 and 8.

Early Diagnosis of Tubercular Peritonitis in Children. A. A. Kissel.—A large number of cases are described in detail out of Kissel's personal experience of fifty-four little patients with tubercular peritonitis. He states that it occurs far more frequently than is generally recognized. In fact, he asserts that almost all the cases of so-called spontaneous abdominal dropsy are in reality nothing but tubercular peritonitis. It may commence with a stormy onset, but in the vast majority of cases it develops insidiously and the family notice merely that the child is growing thin and pale. Under general tonic treatment the effusion may be absorbed and the child restored to perfect health. The diagnosis is aided by the discovery of simultaneous pleuritis with effusion. The most important sign is the thickening of the layers of the peritoneum observed when a fold is pinched up between the fingers—never found in a non-tubercular affection. Even in the absence of any objective manifestations and in apparent health, a thick growth of more or less recent tubercular masses may be palpated in this way on the surface of the peritoneum. The ascitic fluid is very rich in albumin and has a high specific gravity. The diagnosis is most difficult in the rare cases in which a chronic ascites coincides with a tubercular pericarditis.

June 15.

Tuberculosis of the Lymphatic Glands. B. K. Finkelstein.—Ten years' study of this subject with 456 patients, has convinced Finkelstein that tuberculosis of the lymphatic glands is the preliminary to very serious affections. The appearance of small tumors in the glands is an indication of an approaching serious affection. General treatment is sufficient to cure tuberculosis of the glands in the first stage, but in all other stages, operative treatment alone affords favorable results. Injections of arsenic, tuberculin, zinc chlorid and silver nitrate merely hasten the destruction of the gland. The most effective local measure is the application of heat. General treatment and good sanitary surroundings are indispensable to prevent recurrences. In his experience, 7 patients were under 10; 329 or 72.1 per cent. between 10 and 20; 97 under 30; 18 under 40; 3 between 40 and 50, and 2 between 50 and 60. Out of the 201 operated on he has been able to trace only 9 for one to five years after the operation, who have nothing left of the lesion but a linear scar. Recurrence has been known to occur in 43, but the majority of the operated patients have been lost sight of. The wretched hygienic environment of most of the patients has undoubtedly nullified the surgeon's efforts in many more cases than these.

Application of Psychotherapy to Children. R. A. Peters.—This communication describes a number of cures of hysteric affections, incontinence of urine and other neuroses in children between 8 and 15, by suggestion in hypnosis. Peters calls attention to the difference between hypnosis in children and in adults, considering the former essentially different from the latter. In only three out of forty children thus treated was he able to induce the hypnotic sleep as in adults, without verbal suggestion, leading to catalepsy, lethargy and somnambulism. These three were girls of 12 to 14 with chronic hysteria. In all the others, the hypnotizing measures had to be accompanied by verbal suggestion for each stage of the process. The sleep induced was light; somnambulism could be induced, but never catalepsy or lethargy. The awakening is different also. The usual measures, blowing in the face, etc., only caused the children to shut their eyes more tightly and never aroused them, unless accompanied by the verbal command to wake up. This pseudo-hypnotic sleep can be induced in healthy children as readily as in the nervously predisposed, and it is never accompanied by any unpleasant sensations.

June 29.

Streptococcus in Articular Rheumatism. V. E. Predtetchensky.—Pure cultures of the streptococcus were derived by this writer from the blood in two out of five cases of typical acute articular rheumatism. The cultures inoculated into animals reproduced a joint affection resembling in every respect the affection in man whence they were derived.

July 6 and 13.

Histologic Changes in the Puerperal Uterus in Streptococcus Infection. I. J. Klitine.—A long series of experimental researches are reported with the histology of the uteri of gravid rabbits inoculated with cultures of the streptococcus in various ways, sometimes in the mucosa of the vagina, sometimes in the cornu of the uterus or directly into the blood. Marked histologic alterations were observed in every case in the rabbits submitted to this acute streptococcus infection, alike in all cases. The administration of antistreptococcus serum, however, attenuated or entirely prevented these histologic changes. The serum evidently affects the cellular elements in such a way as to diminish the toxic action of the streptococcus. All the animals inoculated at the time the litter was cast, and then treated with the serum, invariably survived the control animals.

Differentiation of Diphtheria Bacilli. I. A. Shabad.—The combined association of pseudo-diphtheria bacilli and of virulent and non-virulent bacilli in varying proportions, has been a fruitful source of error in their differentiation. The specific reaction of these different kinds of bacilli, however, to Neisser's stain is a constant and reliable means of differentiating them in bouillon cultures.

Etiology and Serum Treatment of Malignant Neoplasms. G. M. Vlaeff.—Blastomycetes derived from carcinomata in man have induced neoplasms with the characteristics of malignancy in animals, and Vlaeff has succeeded in producing an antiserum by repeated inoculation of these micro-organisms in geese and she asses. The Journal has already mentioned some of his experiences. He is convinced that all malignant neoplasms are essentially of the same nature, and that the variety observed is due to the special reaction of the tissues of the individual, the site of the tumor, the age, etc. He has seen instances of the simultaneous occurrence of sarcoma and carcinoma in the same patient. He states that with the antiserum derived by repeated inoculations of blastomycetes—saccharomyces hominis—during the course of a year, it is possible to cure a malignant neoplasm in an animal if—and this is the important condition—the neoplasm is still localized, with no metastases. At a later stage, the life of the animal is prolonged, an inoperable tumor rendered operable in many cases, but the affection continues a retarded course unless the neoplasm is extirpated in time. These experiences have been confirmed in every respect in the clinics. He has now an experience of sixty patients thus treated, and describes several cases in detail. Those with a strictly localized tumor, without mestatases in the glands or elsewhere, were improved to such an extent that they can be called cured, all regaining their former weight.

In one case after the tumor had been growing for seven months, the patient was treated with 13 injections of 10 c.c. of the serum in the course of nearly six months. She gained 8 pounds in weight and the tumor retrogressed to such an extent that the surgeons were skeptical in regard to its malignant nature. The remains of the tumor were therefore excised and examined by four Paris clinicians besides Vlaeff, including Brault and Cornil, and all confirmed the assertion that it was a typical, cylindrical-celled carcinoma. The patient has been in perfect health since, now more than a year. She is now 45 years old. In several cases of inoperable recurring malignant growths in the large intestine, the general health was remarkably improved and patients restored to comparative health. He concludes his communication by reiterating that in animals it is possible to completely cure if treatment is commenced before the formation of metastases, and his clinical experiences indicate that the same is true of man.

July 20.

Six Cases of Rupture of the Uterus. V. N. Orloff.—The pelvis was somewhat smaller than usual in each of the 2 cases of incomplete, and 4 of complete rupture of the uterus described in this communication. Two of the latter group died. The fetus was of normal size and weight in each case. Labor had lasted from twenty-nine to forty hours, except in one case in which delivery occurred in eighteen hours. The patients were all multiparæ. In 820 cases Orloff has collected from the literature, the mortality ranged between 55 and 75 per cent. The results vary in proportion to the condition of the patient and the extent of infection, rather than according to the method of treatment selected. Klein's statistics show good results from tamponing, drainage or mere irrigation. In 77 cases of complete rupture of the uterus, 75 per cent. of 28 patients recovered after drainage; 44 per cent. of 46 patients recovered after tamponing, and 50 per cent. of 10 patients with irrigation. In 35 cases of incomplete rupture 100 per cent. of 9 patients recovered after drainage; 50 per cent. of 20 patients after tamponing, and 50 per cent. of 6 patients after simple irrigation. Tamponing is indicated when the hemorrhage persists after delivery; and drainage when a purulent discharge appears several days afterward, especially in case of incomplete rupture. In the absence of hemorrhage and discharge, irrigation is indicated. In Orloff's cases of complete rupture of the uterus, laparotomy was done in 3, but the uterus was not removed in any case. The rent in the two incomplete ruptures extended from the wall of the cervix, commencing at the vaginal portion, to the point of attachment of the broad ligament, where the placenta was adherent. Both these patients recovered with merely vaginal irrigation. In the first case of complete rupture, the rent extended through the left wall of the uterus, and the fetus and placenta had escaped into the abdominal cavity. The uterus was tamponed with iodoform gauze, and laparotomy postponed on account of the weakness of pulse, etc., and the absence of hemorrhage. Symptoms of peritonitis developed, which proved fatal in five days. The rent in the second case extended through the left wall of the uterus and into the left broad ligament, following a tortuous course. The fetus was found in the abdominal cavity. The rupture was sutured through a laparotomy and patient recovered. In the third, the rent started in the anterior wall of the cervix and included the peritoneum, right broad ligament and vesico-uterine pouch, but the fetus had remained in the uterus. The laceration in the cervix was sutured through the vagina, and the broad ligaments, etc., through a laparotomy incision. The patient died eight days later from peritonitis. In the fourth case the cervix was but slightly lacerated, and the rupture chiefly involved the anterior cul-de-sac, the peritoneum of the vesico-uterine pouch and both broad ligaments throughout their entire extent. The fetus had not escaped from the uterus. The cervix was not sutured, but the broad ligaments, etc., were sutured through a laparotomy incision and patient recovered.

Queries and Minor Notes.

MEDICAL PRACTICE ACT.

LAKESIDE PARK, STATELINE P. O., CAL., Aug. 17.

To the Editor:—Will you please state the requirements for the practice of medicine in Montana? M. B.

ANS.—The requirements of Montana are the passage of a satisfactory examination and that the applicant should present evidence of having attended four courses of lectures of at least six months each, if he has graduated subsequent to 1898. Application for circulars, etc., should be made to the secretary, W. C. Riddell, M.D., Helena, Mont.

DR. GOETSCH ON TUBERCULIN.

MANSFIELD, OHIO, Aug. 17, 1901.

To the Editor:—The July 6 issue of THE JOURNAL gives a notice of Dr. Goetsch's paper on tuberculin; it is very important. Can you not give the paper in full? I assure you tuberculin in conjunction with outdoor life is the most promising treatment at our command for tuberculosis. If you can not publish it in full, will you inform me if it has been published in English, and where I can procure it? A. J. E.

ANS.—We do not know of any English translation of the paper mentioned.

NAMES OF SECRETARIES WANTED.

CANTON, N. Y., Aug. 24, 1901.

To the Editor:—Will you kindly give me the address of the secretaries of the state medical examining boards of Michigan and Wisconsin? W. H. G.

ANS.—B. D. Harison, M.D., Sault Ste. Marie, Mich., and H. M. Ludwig, M.D., Richland Center, Wis.

CELLOIDIN THREAD.

NASHUA, N. Y., Aug. 24, 1901.

To the Editor:—In reading the last number of THE JOURNAL my attention was attracted by the experience of Dr. A. Hammesfahn in simplifying suture process by using celloidin thread. In looking up the literature, I find no data on that kind of suture. Please tell me where I could procure some of that material, and oblige. A. G.

ANS.—We do not know where this can be obtained in this country, but Pagenstecher's celluloid thread is probably the same thing; its advantages are reported on by Drs. Keen and Rosenberger, whose article was published in the *Philadelphia Medical Journal*, of March 10, 1900, and abstracted in THE JOURNAL, March 24, 1900, p. 741.

New Patents.

680,122. Apparatus for vaporizing medicinal agents. Erasmus T. Camp, Gadsden, Ala.

679,890. Apparatus for measuring errors of refraction. Louis L. Ferguson, New York City.

679,980. Bandaging table. Benjamin G. Miller, Cumberland, Md.

679,993. Adjustable adhesive supporting plaster or bandage. John G. Ross and H. M. Taggart, Philadelphia.

679,784. Exercising machine. Michael B. Ryan, London, Eng.

680,179. Toilet-disinfecting apparatus. Leon C. Schoneman, New York City.

679,918. Shield for wounds. Edward C. Shears, Lakota, N. D.

679,802. Operating table. Thomas M. Vaughan, Mattoon, Ill.

679,925. Artificial ear-drum. Laura H. Vickers, West Philadelphia, Pa.

680,384. Fumigating and disinfecting. Charles T. Kingzett, Chiselhurst, Eng.

680,436. Shoulder-blade extractor. Elmer P. Nichols, Stamford, Conn.

680,556. Exerciser. Henry W. Wieland, London, Eng.

The Public Service.

Army Changes.

Movements of Army Medical Officers under orders from the Adjutant-General's Office, Washington, D. C., Aug. 8 to 14, 1901, inclusive:

Dallas Bache, colonel, assistant surgeon-general, sick leave extended.

James L. Bevans, contract surgeon, now at San Francisco, Cal., is relieved from further duty in the Department of Alaska, and assigned to duty in the Department of California.

William C. Borden, major and surgeon, U. S. A., leave of absence extended.

Henry F. Hoyt, major and surgeon, U. S. Vols., leave of absence extended.

John S. Kulp, captain and asst.-surgeon, U. S. A., detailed a member of an examining board in New York City and at Governor's Island, N. Y., during the temporary absence of Lieut. Allie W. Williams, asst.-surgeon, U. S. A.

Herbert G. Shaw, lieutenant and asst.-surgeon, U. S. A., member of an examining board at San Francisco, Cal., *vice* William M. Roberts, lieutenant and asst-surgeon, U. S. A., relieved.

Louis A Thompson, contract surgeon, now at San Francisco, Cal., will proceed to Washington, D. C., and report to the surgeon-general for instructions.

Samuel M. Waterhouse, lieutenant and asst.-surgeon, U. S. A., previous orders directing him to proceed to San Francisco, Cal., en route to the Division of the Philippines, revoked.

J. Samuel White, contract surgeon, previous orders revoked. This revocation appears to leave him as relieved from duty at the General Hospital, Presidio of San Francisco, Cal., and under orders to proceed to Fort Gibbon, Alaska, for duty.

Navy Changes.

Changes in the Medical Corps of the Navy, week ended Aug. 17, 1901:

Medical Inspector F. Rogers, detached from the *Brooklyn* and ordered home.

Surgeon J. E. Gardner, detached from the Naval Hospital, Cavite, P. I., and ordered to the *Brooklyn*, temporarily.

P. A. Surgeon M. S. Elliott, detached from the *Annapolis*, and ordered to the *Kentucky*.

P. A. Surgeon E. M. Shipp, ordered to the Cavite Naval Station.

Asst.-Surgeon W. H. Ulsh, detached from the *Glacier* and ordered to the *Annapolis*.

Asst.-Surgeon W. E. G. High, detached from the *Kentucky* and ordered to the *Glacier*.

Asst.-Surgeon J. T. Kennedy, detached from the Marine Brigade, and ordered to the *Brooklyn*.

Asst.-Surgeon H. E. Odell, detached from the Naval Hospital, Cavite, and to duty with the Marine Brigade.

Marine-Hospital Changes.

Official list of the changes of station and duties of commissioned and non-commissioned officers of the U. S. Marine-Hospital Service for the seven days ended Aug. 15, 1901:

P. A. Surgeon H. D. Geddings, granted leave of absence for one month and fifteen days from August 15.

P. A. Surgeon C. H. Gardner, granted leave of absence for fourteen days from August 17.

Asst.-Surgeon S. B. Grubbs, granted leave of absence for three days from August 12.

Asst.-Surgeon J. F. Anderson, relieved from duty at Liverpool, England, and directed to proceed to New York City, and await orders.

Asst.-Surgeon C. H. D. Lord, granted leave of absence for seven days under paragraph 178 of the Regulations.

A. A. Surgeon B. W. Goldsborough, granted leave of absence for seven days from August 11. Granted leave of absence for twenty-one days from September 5.

A. A. Surgeon R. S. Primrose, granted leave of absence, on account of sickness, for 21 days from August 10.

A. A. Surgeon S. D. Robbins, granted leave of absence for thirty days from August 5.

Hospital Steward F. R. Hanrath, granted leave of absence for ten days from August 12.

Hospital Steward M. Walerius, granted leave of absence, on account of sickness, for twenty-three days from August 8.

Health Reports.

The following cases of smallpox, yellow fever, cholera and plague have been reported to the Surgeon-General, U. S. Marine-Hospital Service, during the week ended Aug. 17, 1901:

SMALLPOX—UNITED STATES.

Kansas: Wichita, July 27-Aug. 3, 1 case.
New Hampshire: Nashua, July 27-Aug. 3, 2 cases.
New Jersey: Newark, Aug. 3-10, 4 cases, 1 death.
New York: New York, Aug. 3-10, 36 cases, 13 deaths.
1 case.
Aug. 3-10, 8 cases.
. 3-10, 1 case.
Washington: Tacoma, July 28-Aug. 4, 3 cases.
Wisconsin: Milwaukee, Aug. 3-10, 1 case.

SMALLPOX—FOREIGN.

Brazil: Pernambuco, June 15-July 15, 81 deaths; Rio de Janeiro, June 1-30, 52 deaths.

Colombia: Panama, July 29-Aug. 5, 7 cases, 1 death.

Egypt: Cairo, July 1-22, 2 deaths.

France: Marseilles, June 1-30, 4 deaths; Paris, July 20-27, 3 deaths.

Great Britain: Dundee, July 20-Aug. 3, 6 cases; Glasgow, July 27-Aug. 2, 2 cases; London, July 20-27, 11 cases.

India: Bombay, July 8-16, 6 deaths; Calcutta, July 6-13, 3 deaths; Madras, July 6-13, 8 deaths.

Italy: Messina, July 20-27, 19 cases, 16 deaths; Naples, July 14-28, 99 cases, 10 deaths.

Mexico: Mexico, July 21-28, 1 death.

Russia: Moscow, July 13-20, 4 cases, 2 deaths; Odessa, July 20-27, 3 cases; Warsaw, July 13-20, 3 deaths.

Spain: Barcelona, July 1-20, 5 deaths.

Uruguay: Montevideo, June 8-15, 12 cases.

YELLOW FEVER.

Colombia: Bocas del Toro, Aug. 2, 1 death.

Costa Rica: Port Limon, Aug. 3, 4 cases, 1 death.

Cuba: July 27-Aug. 3, Havana, 3 cases, 1 death; Marianao, 1 case, 1 death: Pinar del Rio, 1 case; Regla, 1 case, 1 death.

CHOLERA.

India: Bombay, July 6-13, 15 deaths; Calcutta, July 8-16, 2 deaths.

Java: Batavia, June 22-July 6, 63 cases, 43 deaths.

PLAGUE.

China: Hongkong, June 22-July 6, 109 cases, 107 deaths.

India: Bombay, June 8-16, 101 deaths; Calcutta, July 6-13, 16 deaths.

Original Articles.

THE PRACTICE OF OBSTETRICS.*

E. GUSTAV ZINKE, M.D.

Professor of Obstetrics and Midwifery, Medical College of Ohio, Medical Department University of Cincinnati; Obstetrician and Gynecologist to German Hospital; Obstetrician to Ohio Maternity Hospital.

CINCINNATI, OHIO.

If the question is asked: Is there room for improvement in the general practice of obstetrics, it is answered in various ways.

Those physicians and surgeons, whether obstetricians or not, who have studied carefully the character of the present mode of the practice of midwifery, have but one answer: The daily practice of obstetrics is not what it ought to be for mother, child nor the physician.

Some of the general practitioners, the so-called "lucky fellows," who have attended a large number of obstetric cases without a single sad experience (*sic*) will shrug their shoulders and say: Were it not for the great loss of time connected with waiting upon women pregnant, in labor and confinement, and the poor pay, we should be perfectly satisfied.

There are others in the rank and file of the profession, especially in the country districts, who claim: We are trying to do entirely too much in the practice of obstetrics. Only a few of the labor cases make trouble if permitted to take care of themselves.

Others cry out: Abolish the midwives. They are a source of mischief in the management of pregnancy, labor and confinement.

It is evident, from these statements and my own personal experience, that the present practice of obstetrics is not as satisfactory as it might be to any one class of practitioners of medicine and surgery generally, and the accoucheur especially; and certainly not so far as the average results regarding the mother and child is concerned.

What is the remedy? The writer belongs to those who believe that the practice of obstetrics can and ought to be improved in many ways. The principal questions which concern us are not so much those of time, pay and midwives, but rather of how and where can the best result be obtained.

Antisepsis and asepsis in the management of labor are of inestimable value; many lives have been saved by a thorough appreciation and application of the same. The mechanism of labor, the art of diagnosis of the attitude of the fetus *in utero*, and the art of taking the measurements of the maternal pelvis are well understood. Complications resulting from maternal diseases or deformities, or from malpositions or disease of the fetus, may be recognized in ample time. But what does it avail us when all of these, though scientifically applied, promptly determined and correctely interpreted, can not be properly carried out, successfully executed, or effectually met, because of the patient's surroundings? On this account, the knowledge and skill which we may possess and the care which we are ready to bestow upon the patient, are much reduced in value, and invalidism, disease and sometimes death follow where naught but health and happiness ought to prevail.

The present custom is to attend women in confinement at their homes. Only a small percentage is delivered in hospitals established and equipped for that purpose. By far the great majority of the women who go to maternities do so because they have no home. A few, very few, because they have not the means to pay for the services of a physician (or midwife) and nurse.

During the 26 years of my professional career, of which 15 were devoted to general practice, and 11 almost exclusively to the teaching and practice of obstetrics and diseases of women, I have had ample opportunities to observe and experience the difficulties attending the delivery of women at their homes and learn to appreciate the great advantages which lying-in hospitals possess over the long-established, deep-rooted but old and unscientific custom of confinements at home.

The most luxurious furnished and most favorably situated home, provided with all the modern sanitary arrangements, is not superior in safety to the most humble but well prepared and properly conducted maternity hospital! The reasons for this assertion are apparent, numerous and convincing.

For the sake of illustration let me divide the community into three, more or less, distinct classes:

1. The wealthy who can afford, or do not hesitate at least, to spend money lavishly when it concerns their personal safety and comfort.

2. The middle class, who live in their own modest little home, or, perhaps, in a so-called flat, or, as we sometimes find them, in a well-kept tenement house.

3. The absolutely poor, indifferent and uneducated, who, in the majority of instances, either because of necessity, carelessness or ignorance, occupy but one little, poorly-ventilated room, in a miserable hovel, located in a neighborhood defiled with filth and disease.

Class 1. By reason of their wealth and a comfortable home this class is enabled to engage the most competent and efficient service, an experienced obstetrician and well-trained nurses. One or even two rooms of the capacious residence may be set aside and fitted up like an operating or private room in a maternity. The nurses render everything (the patient and themselves included) as clean, neat and aseptic as it can possibly be done in the best hospital. The physician not only secures a sterilizer, but provides himself with all possible instruments, dressings and medicines in order to meet promptly and, if possible, successfully any complication or emergency that may arise immediately before, during or after the event.

---

* Read at the Fifty-second Annual Meeting of the American Medical Association, in the Section on Obstetrics and Diseases of Women, and approved for publication by the Executive Committee of the Section: Drs. A. H. Cordier, W. E. B. Davis and Henry P. Newman.

It would seem that, under the conditions and surroundings just described, in conjunction with the prospect of a handsome fee, it would be a great pleasure and an extreme satisfaction to practice the art of midwifery. No doubt it is so in some instances. But you know that the obstetrician, who wants to provide for every emergency and accident that may befall a woman in her confinement, has a great task on hand. And, forsooth, after he has brought upon the scene everything that might possibly be needed, he may discover to his great dismay, if not intense mortification, as well as the serious disadvantage of his patient, that he has forgotten the very thing he wanted most—though simple and insignificant it may be.

There is an impression abroad that the modern obstetrician puts his patient to much needless trouble, because of his extensive preparations. This is, apparently, supported by the daily observation that women pass through confinements with apparent safety to themselves and the newly born, in many instances without the aid of a skilled and experienced accoucheur, a trained nurse, and sometimes even with or without the help of a midwife. The above impression is fur her supported by the occasional loss of a mother or child, or both, in spite of all previous preparations, the presence of talented assistance and the greatest possible care during the labor. There are even "good" (?) doctors who counsel against the taking along any kind of instrument "for fear of using the same." These gentlemen always smile significantly when they see a young, well-trained and conscientious physician go to all the so-called "needless" trouble of preparing a woman and her surroundings for the approaching confinement.

Class 2. Nearly all of what has been said of the wealthy holds good of the middle class. There will be, however, but one nurse, if any, and she may or may not have had a systematic training; quite often she has no training at all. There will be no room especially set aside and prepared for the confinement. The most liberal and thorough use of antisepsis will only result in an imperfect aseptic condition of the patient, her bed and surroundings. The doctor's remuneration is very moderate, as a rule; sometimes it is distressingly small and occasionally it is not paid at all. This is especially true if all is not satisfactory. At any rate, in every instance the management of the case is handicapped from the beginning; its conduct becomes difficult and dangerous to the patient and rests like a heavy burden upon the obstetrician in charge. Let unforeseen complications arise or accidents occur, the embarrassment which follows because of the inability to meet them properly and promptly is often great and, not infrequently, leads from bad to worse and may result in serious injury, disease and even death. The obstetrician has labored hard. He is worn out by long-continued physical effort and prolonged mental strain in his anxious attempt to bring the case to a successful termination. He retires from the scene fully conscious that he has done his duty. He also knows that there will be no reward for his work, aye, that he will be damned if the result be an unfortunate one.

Class 3. The absolute poor, indifferent and uneducated, as may well be imagined, fare worse by far than the two preceding classes. The wonder is that any of the mothers escape the evil consequences of lack of proper attention, the dangers of sepsis, and that so many of the children survive, live and grow up.

As a rule there is little or no provision made for the care of the mother and the arrival of the infant. The assistance obtained is often seriously wanting in promptness and earnestness as well as knowledge and experience. Of late years, in the larger cities at least, outdoor obstetric clinics have been established; they are supported by colleges and maternity societies. Through these clinics the condition of the patients belonging to this class and who avail themselves of the advantages of those institutions, is somewhat improved, but far from tolerable. A recent graduate or senior student of medicine and sometimes a trained nurse is the help furnished these women. They are provided with antiseptics, sterilized dressings, etc.; but when difficulties and serious complications are threatened or do occur, the patients are promptly transferred to a hospital. It is because of this that the records of the outdoor clinics remain good, while the records of the hospitals correspondingly suffer. When a transfer to the hospital is refused, or the condition of the patient forbids removal, the officers of the clinic are called in to direct the future management of the case, and, sometimes after a great deal of hard work and plenty of time, the patient recovers. To what extent will always remain a question.

Probably the best evidence that the practice of obstetrics is not what it ought to be lies in the fact that, while we have plenty of teachers of obstetrics, we have not, in the ordinary meaning of the term, a single specialist in this department here or elsewhere. Why? 1, because there is not money enough in the practice of obstetrics to maintain a man and his family respectably; 2, because the work is hard and full of responsibility; and 3, it is often associated with unmerited blame and unjust criticism, to say nothing of the loss of time, sleep and irregular hours generally. Is there anything that upsets the busy practitioner's work more than a case of labor? This is the rule. The exceptions are few. There is, so far as my observation goes, no satisfaction in the private practice of midwifery as it is conducted at the present day.

From what has been said it would seem that little, very little, can be offered in favor of attending women (rich or poor) in the act of birth at their homes. The only objection to hospital deliveries that I have thus far heard and deserving of an answer is: "There is more danger of sepsis in the hospital than at home, because septic cases are constantly sent to the hospitals." It is true that septic cases are—and they should be—admitted to maternity hospitals. Why? Because there women thus affected have the be [illegible] ecover. This alone speaks volumes in [illegible] It is so because the necessary provisions have been made for the accommodation of these cases. Not only are the septic patients kept separate and by themselves, but superior facilities exist—or should exist—to treat these cases not only effectually and successfully, but to prevent a spread of the malady at the same time. More than that; the disease should be actually stamped out, if everything is done that can be done with that object in view.

The argument that women love their homes and abhor the idea of going to a hospital for the purpose of confinement is only a sentiment begotten of custom and deserves no special refutation. Let women once appreciate that the hospital is the safest place for them to pass through the ordeal of labor, they will seek it of their own accord.

There was a time, not so very many years ago, when the men who argued in favor of hospitals as the proper place for the performance of a major surgical operation of any kind, were looked upon as unreasonable, selfish, short-sighted individuals; they were regarded as men prompted by greedy motives, nothing else.

How many capital operations are performed to-day at the houses of patients? Very few, indeed! At present men, women and children are taken to hospitals, not only for the purpose of having dangerous operations performed upon them, but they are taken there for trifling injuries and diseases. The results are good; better than before. Consequently everybody is satisfied. Objections are seldom heard.

Will anybody argue that the act of giving birth to a child is not a capital operation? Or an event free from special danger? Who will claim that every woman pregnant is hopeful and cheerful, because she knows she will pass through her labor safely and unharmed? Who is there that can always predict with certainty that there will be no complications and, if there are, that he can meet them with as much success as in a hospital equipped for this specific purpose?

A simple ovariotomy does not carry with it so grave an element of danger as does a normal case of labor. Yet every abdominal surgeon knows that, when he performs ovariotomy, though simple in its aspects, at the house of his patient, he does so at a greater risk than at the hospital. The care is far greater and the responsibility he assumes much more grave when he operates at the house. At the hospital he has but to say what he intends to do and when he wants to do it. Everything is then prepared for him. He has no care of minor details and he can concentrate his whole mind upon the work to be performed. Not so when he operates at the home of the patient. Here he must himself supervise all the details necessary for the success of the operation and the recovery of his patient; and still he runs the risk that, just prior to, during or immediately after the operation, something very important is wanting or has been left undone.

This is never more true than in a labor case attended at the patient's home; and yet, both the women and the great majority of physicians object (some of them earnestly and persistently) to maternity hospitals. Why? Because the former are not accustomed to it; the latter are apprehensive that they may lose a stronghold upon their patrons through which and through whom they believe to obtain the good will and confidence of the one and other families.

The prejudice against hospital deliveries can be as easily overcome, in my opinion, as the antipathy which existed in the past against the hospital for any kind of treatment, medicinal or surgical.

I have had occasion to attend ladies in confinements who were suddenly taken in labor while traveling, and who had no other choice than to go to a hospital. Some of them had had previous, others subsequent experiences of the same kind at their homes. All were unanimous in their expressions that the hospital is the better and the most convenient place for confinement purposes. It, too, has been my satisfaction of late not only to deliver the wives of prominent citizens at the hospital, but also the wives of some of my professional brethren. In every instance the difference between home and hospital was keenly appreciated and the verdict invariably in favor of the latter.

The fear that the family physician will suffer by the change and that the young physician will be deprived of a legitimate opportunity to "obtain practice," is imaginary, not real. Maternity hospitals should be so conducted that they would please the humblest as well as the most fastidious. Let the patient and her friends make their own selection of accommodations. The absolutely destitute should be admitted free of charge. Others should pay what they can, or for what they want. The latter two classes have the privilege of employing their own physician. This gives the family physician, if there is one, still the first choice. This being so, the doctor not only continues to sustain the same relations to his clientele as before, but it makes his work easier, safer and more satisfactory. He need no longer trouble himself with the minor details; the help he may want is there and already well trained; whatever instruments, dressings or other articles he may need without delay, will be ready for use; all he is to do is to look to his own aseptic condition and then help himself or ask for what he may need. His results will, therefore, be better; the work itself much more agreeable and not half so burdensome as when the patient is delivered at her home. He will thus save the patient's health and wealth, himself a great deal of time and worry, increase his reputation and be better paid in the end, financially and otherwise.

In our larger cities hospital accommodations are already very extensive, but by no means sufficient. The smaller cities and towns are beginning to build hospitals, and there is no good reason why the smallest village should not erect a hospital for this purpose alone, if not for any other. Where hospitals do not or cannot exist the practice of obstetrics must, of course, be carried on as in the past.

POSITION OF THE WOMAN DURING DELIVERY.*

WILLIAM D. PORTER, M.D.
CINCINNATI, OHIO.

The literature of this subject is practically confined to two questions: 1. What effect has posture on the mechanics of labor? 2. How does posture affect the pelvic diameters?

It is not the purpose of this paper to discuss either of these questions; but rather to consider posture with reference to its bearing on sepsis, and to determine, if possible, what position is most conducive to an aseptic technique. The plan of delivering the woman as she lies in bed—the amniotic fluid, the child, the blood, the placenta and often fecal matter being received by the bed or its protections—has had from antiquity to the present, the sanction of universal custom. With such conditions an aseptic technique is incompatible. In the homes of those who are able to command the comforts and some of the luxuries of life, these unfavorable conditions can be greatly modified.

Given a clean patient in clean garments, a firm mattress with clean protectives, sheets and pads, together with a competent nurse, and the danger is largely, though by no means entirely, eliminated. Under the most favorable circumstances there are dangers of infection which would not be tolerated in a surgical operation. When the head is on the pelvic floor, in spite of all preliminary preparation, fecal matter may escape coincident with the pains; and, if the labor is about to terminate, the nurse has not the necessary time for again cleansing the patient. Infection may occur through soiling the hand, which in the necessary haste, the accoucher might easily overlook. Or an accumulation of fluids may float fecal matter into contact with lacerations or abrasions or even into the vagina. The serious infections of the colon bacilli probably occur in some such way. Unless the mattress be exceptionally firm, the woman's hips occupy a depression which will be filled with fluids. When we recall the relaxed condition of the vaginal outlet at the end of labor, the wonder is that infection does not oftener occur.

---

* Read at the Fifty-second Annual Meeting of the American Medical Association, in the Section on Obstetrics and Diseases of Women, and approved for publication by the Executive Committee of the Section: Drs. A. H. Cordier, W. E. B. Davis and Henry P. Newman.

This danger of immediate infection is not lessened by the Kelly pad as ordinarily used. It protects the bedding admirably. But with the woman in the ordinary position on the ordinary mattress, fluids will not drain away from the parts, owing to the depression in which the hips lie. The pad prevents the rapid escape and absorption of fluids, and by holding a pool about the vulva, the chances of infection are increased. This objectionable feature is sometimes overcome by following the English custom of placing the woman on her side with her hips well to the edge of the bed. In this position the Kelly pad can be well utilized. But it is a position in which it is difficult to control the patient, particularly when she is partially anesthetized. It involves flexion of the thighs which distinctly increases the danger of perineal laceration. And, moreover, it is a position which has never met with favor in this country.

For years it has been the invariable custom of the writer to deliver in the following position: The woman lies on her back across the bed, her hips well to the edge and on a Kelly pad, so arranged as to carry fluids into a vessel on the floor. For this purpose, the small square pad is most suitable. The patient's legs are separated and extended. They are supported by assistants, by a couple of suitably placed chairs, or—and preferably—over the knees of the obstetrician, who sits on a chair facing the bed at a convenient distance. She should wear her stockings, her thighs should be enveloped in clean towels and she should be covered with a sheet. This position is maintained from the end of the first stage until the termination of labor, unless the second stage be tedious. In that event, the patient can resume her ordinary position in bed, to be again brought into the position described before the end of the second stage. The position is not tiresome to the patient or physician and can be maintained for hours without discomfort to either.

The first thing after placing the woman in this position, is to have the nurse thoroughly cleanse the external genitals and inner surfaces of the thighs with a generous application of soap and hot water, followed by an antiseptic solution. This should, for obvious reasons, be a routine procedure, irrespective of previous preparation. It corresponds to the final preparation of the site of a surgical operation. It is claimed for this position that, with intelligent management, the parts so cleansed will not be infected during the labor. In case fecal matter escapes during a pain, it gravitates at once to the vessel on the floor, and all traces which could offend the sense of sight or of smell, are swept into the vessel by the free application of an antiseptic solution. The maintenance of a fixed position is unquestionably favorable to asepsis. The patient is less likely to contaminate the parts than if she were permitted to frequently shift her position. The physician can much more certainly keep his hands clean than if he were compelled to move about to accommodate himself to the changing position of his patient. He is constantly prepared to render assistance, and thus avoids the too common blunder of managing the termination of labor with hands improperly cleansed, on account of haste at the last moment.

This position also reduces the number of vaginal examinations. The examinations usually made from time to time by the accoucher, that he may be apprised as to the probable termination, are not necessary. Within reasonable limits, the time makes no difference, as the position insures constant readiness on his part.

This position, better than any other, insures control over the advance of the head as it is about to emerge. In the ordinary position the degree of control is by no means satisfactory. Unless anesthesia be profound, the woman is likely to toss about at the critical moment. This often results in a needless degree of laceration. The position advocated eliminates this unfavorable element. The patient, unable to secure points of resistance for her feet, can not change her position. The obstetrician is in complete control and can delay, to the most favorable time, the delivery of the head and can manage accurately the rate of advance when it is delivered.

When delivery occurs, first the head and then the body is grasped, and the child is carried up over the pubes. The nurse places the blanket, in which the child is to be wrapped, across the abdomen and pubes of the mother. On this the child is placed transversely and low enough to permit of ready manipulation of the uterus. This avoids the danger to the child of infecting the eyes or cord with fecal matter and there is less liability that it may aspirate fluids into the air passages. Before the child is moved the cord is dressed and dressing secured by a binder. To allow quite an interval to elapse between the cutting and the dressing of the cord, with the possible danger of infection, is an unsurgical procedure. The facility afforded by this position for the delivery of the placenta and for the detection and repair of perineal laceration needs no comment.

Of no very slight importance is the ease with which the patient can be cleansed at the termination of labor. No other position permits such free use of water. If ordinary care has been used the woman is clean and her garments and bedding spotless.

We have been considering that small minority of patients who live in well-appointed homes and command the services of the trained nurse. The vast majority of child-bearing women are unable to secure these safeguards. The membership of the lower classes is prolific as well as numerous. Living, as they do, in cramped quarters, the bath-tub an unknown luxury, it would be unfair to expect a high standard of household or personal cleanliness. In isolated cases, the housewife rises superior to her surroundings and is a model of neatness and cleanliness. She is the bright exception to the general rule of dirt and disorder. If the woman of this class is able to have in readiness, at the time of her labor, a change of linen for her bed and a few clean towels, she feels entitled to credit. She probably depends for nursing on some member or friend of the family; or much worse, on a so-called nurse, but one without training, and whose ignorance of asepsis is equalled only by her assurance, and her readiness to act on her own initiative and in defiance of instructions. In this class the young physician, struggling to make his way, finds most of his obstetric work. Should he choose the usual position for delivery, his examinations are fraught with danger. Bedding and patient are likely to be in a sorry plight at the end of labor, and the chances are that these conditions will continue during the lying-in period.

If he adopts the position herein recommended he needs only soap and sterilized water to insure safety to his patient. A liberal application of soap and the use of a large fountain syringe of hot water, followed by an antiseptic solution, comprises a ready means of cleansing the external parts. If necessary, this can be done by the physician, and there is need of little or no exposure. If he will exercise the forethought to sterilize forceps, ligatures, sutures, needles, scissors, etc., and place these within convenient reach, it will be unnecessary for him to leave his chair until the labor has terminated and every necessary detail has received attention. He is in complete control of the situation and protects his patient from infection in the most unfavorable surroundings.

Incidentally, in an emergency such as post-partum hemorrhage, this position is advantageous. There is necessarily a prompt notification of the danger, and the woman is already in the most favorable position for treatment. Moreover, the young physician will find the position the best for studying the mechanism of labor.

In conclusion a brief recapitulation embraces the following claims for this position:

1. There is less liability of infection with fecal bacteria.
2. Fewer examinations are necessary.
3. There is better control of the head at the time of delivery, and consequently less danger to the perineum.
4. The woman can be more thoroughly cleansed after labor, and clothing and bedding are not soiled.
5. There is less danger of infecting the eyes or cord of the child and less risk of its aspirating fluids into its air passages.
6. In managing cases in the unfavorable environments of the lower classes, the position is especially valuable to the young physician, whose experience is gained largely among these classes.

THE PROPHYLAXIS AND TREATMENT OF PUERPERAL SEPSIS.*

JOHN F. MORAN, M.D.

Professor of Obstetrics, Medical Department, Georgetown University; Obstetrician to Columbia and Georgetown University Hospitals.

WASHINGTON, D. C.

The recent developments in bacteriology and pathology have demonstrated conclusively the fallacy of the previously accepted theory of the essentiality of puerperal sepsis, and likewise have been able to explain its manifold manifestations by showing that wound infections and puerperal infections are identical and may be due to a variety of pathogenic organisms. Streptococcus, staphylococcus, bacillus coli communis, gonococcus and pneumococcus are the most frequent causes of puerperal infection, while the bacillus of diptheria, anaerobic and other micro-organisms have been demonstrated to be occasional factors in the pathogeny.

Streptococcus pyogenes is found in the body under a variety of circumstances, and is probably the most important cause of septicemia and pyemia following wounds of ulcerative endocarditis, of tonsillitis and erysipelas. Bacteriologic investigation shows it to be the most frequent cause of the various septic processes following labor, and it may be found pure or associated with other organisms. It has long been recognized that its manifestations are varied and that they depend upon several factors: the nature of the organism; the soil; the dose of virus, and the place of entrance. The most important factors are the virulence and character of the infecting organism. Variation is common to different specimens of the same species. Under certain conditions the virulence is increased, while under others it may be decreased or attenuated. It may produce abscesses at the point of inoculation, which may, or may not, become diffused throughout the body, or it may even cause death without the appearance of any local change.

The staphylococcus and colon infection are as a rule milder forms of sepsis, but Strunkman has collected twenty-five fatal cases of the former and three of the latter. The writer has seen one fatal case of staphylococcus aureus and two of the colon variety.

The parturient tract has been aptly compared to a surgical wound and it is easy to conceive, that, with the contusions and lacerations together with the lowered resistance of the system incident to labor, the conditions are very favorable for the development of germs when once they are introduced. According to Widal, Baum, and Gärtner, the placental site is the favorite point of invasion of the infecting germs, either by way of the lymphatics, or veins, or both. Yet infection frequently takes place from wounds of vagina and cervix.

The results of the bacteriologic examination, with regard to the presence or absence of pathogenic germs in the vaginal secretion under ordinary conditions, are by no means in harmony. Gonner and Döderlein in 1887 investigated the subject and, while the former obtained negative results, the latter obtained many varieties of pathogenic organisms, including streptococci. Since then, numerous capable observers have investigated the subject with variable results. Menge, Kronig, and Williams have gone over the work very carefully and find that the uterus and vagina, under ordinary conditions, are sterile as regards pathogenic organisms, and, that the discrepancies of other observers are due to faulty technique in obtaining cultures. Further, the investigations directed more particularly to the vulva, show that it is rarely, if ever, free from pathogenic organisms, and that it is almost impossible to render it so.

Döderlein attributes the absence of pathogenic organisms in the vaginial secretion to the bactericidal influence of the acid products of the vaginal bacillus. Kronig does not think this view justifiable and believes that several factors play a part, namely: chemical substances in the secretion, probably acids; antagonism of the bacteria living in the vagina to imported bacteria; leucocytosis and phagocytosis; lack of oxygen and tissue juices.

From the foregoing survey of the literature, it is seen that the uterus, under normal conditions, is sterile and some hold a similar view regarding the vagina; but all authorities agree that the vulva is scarcely ever free from pathogenic organisms. We can readily understand then, how easy it is to infect the vagina and uterus even by simple internal examination, or the giving of a douche. Further, the experiments of Bumm, Döderlein, Kronig and others show that antiseptic douches tend to impair the normal bactericidal influence of the vaginal secretion, and, as the pathogenic organisms are not destroyed, or diminished in number, their use should be dispensed with. Pestalozzi reports 4000 cases confined in the Maternity in which no ante-partal or post-partal douches were employed. It was only necessary to isolate 33 and of these, 30 recovered. These results are in accord with those reported by Leopold, Merman, Goldburg, Zweifel and others who have treated cases with and without douches. Again, let us compare the results obtained in the lying-in hospitals of Europe before the pathologic anatomy period, in which only prophylaxis was used. Vienna from 1786 to 1822, had a total death-rate of 6 per cent. in 44,858 cases. The Dublin Rotunda Lying-In Hospital in 93 years, from 1757 to 1849, had 1.23 per cent.; and the British Lying-In Hospital during the same period shows a mortality of only 2 per cent. It can hardly be sustained that the antiseptic treatment has accomplished all that has been claimed for it.

---

* Read at the Fifty-second Annual Meeting of the American Medical Association, in the Section on Obstetrics and Diseases of Women, and approved for publication by the Executive Committee of the Section: Drs. A. H. Cordier, W. E. B. Davis and Henry P. Newman.

So it is seen that recent bacteriologic and clinical investigations are in accord, and the antiseptic treatment, which has steadily gained ground from the time that Semmelweiss showed a causal relation of cadaveric poison to puerperal sepsis, is gradually giving away to the more rational idea of asepsis. Routine douches, before and after labor, are being discarded, and our attention is being directed to the thorough cleansing and the disinfection of the external genitalia, of the hands of the physician and nurses, of the instruments, dressings, etc., and to the avoidance or restriction of internal examinations.

The treatment should vary according to the character of the infection. It may be local, with a view of removing or destroying germs at the point of infection; or general, by use of measures to neutralize the introduced bacteria or their toxins, and to fortify the system in its struggle against the infectious germs; or surgical, to remove collections of pus, and organs that may have become a menace to the welfare of the patient. It is well to regard every case of fever occurring during the puerperium as septic, until proved not to be so by a searching investigation. Our first duty, after obtaining a history of the case, should be to make a careful and thorough bimanual and specular examination of the uterus and pelvic organs. If there be lesions of the external genitals or vagina, they should be appropriately treated and the uterus not invaded unless indications point to infection of that organ. The possibility of pus existing in the pelvis before labor, due to pyosalpinx, ovarian or appendiceal abscess, should be borne in mind. If these and other causes of pyrexia, such as malaria, typhoid fever, etc., can be excluded, the uterus should be gently explored with the finger, or, dull curette, and any placental debris or clots removed. If possible, a bacteriologic culture should be taken directly from the uterus, and then an intra-uterine douche, preferably of sterile water, or sterile salt solution, should be given. Should the bacteriologic examination reveal saprophytic infection, the douche may be repeated, especially if the temperature remains elevated and a foul-smelling discharge continues.

If it proves to be a case of pathogenic infection, further local treatment is contraindicated, as it can not possibly reach the organisms which have penetrated beyond the reach of such measures. If the infection has spread into the broad ligaments, as may be manifested by the extension of the pain over the region and the revelation of a boggy sensation on vaginal examination, the lymphangitis and localized peritonitis must be combatted by the application of the cold pack, or preferably, the rubber coil applied to the lower abdominal region, and the giving of anodynes to relieve the pain.

I am confident that the repeated giving of intra-uterine douches and the use of the curette in streptococcus infection, is decidedly harmful. The danger of introducing other germs and causing a mixed infection, and, the production of more or less traumatism of the endometrium, thereby breaking down Nature's protective zone of leucocytes, and opening up new avenues for wide-spread systemic infection, are strong arguments against injudicious local treatment. Again, the use of large quantities of the bichlorid of mercury and other antiseptic solutions, as recommended by many authorities, would seem to be irrational because of the invasive qualities of the streptococcus; it can not exercise its germicidal effect, besides there is great danger of poisonous effect from absorption. Douches are only necessary to wash away any retained debris, therefore sterile water and normal salt solution are to be preferred, as they are harmless.

The general treatment will embrace the use of strychnia, nitroglycerin and stimulants to strengthen the heart. The amount of stimulation that septic cases will bear, is surprising. I have seen so much as a quart of brandy used daily for two weeks with good results. Antipyretics should not be given as they depress the heart; quinin is of little avail, except in malaria—besides, given in large doses it is apt to derange the stomach.

Nuclein and albumose have been used for the purpose of increasing leucocytosis, and in recent years normal salt solution subcutaneously, or by the bowels, is being received with much favor. It is a rational measure—for it flushes the kidneys, eliminates the toxin and stimulates the heart. Mace, Fouchier, and others, recommend baths at a temperature 77 F., repeated every three hours and claim to have obtained good results.

The results from the use of anti-streptococcus serum have on the whole, been disappointing. Statistics show the mortality to be about 35 per cent. Many of the failures may have been due to the inferior quality of the serum. It is important to determine whether the case be one of simple or mixed infection. Curative effects are claimed for only a simple streptococcus infection. The most plausible explanation of failure would seem to be that offered by Smith, who says: "When we come to deal with those bacteria which do not produce a soluble diffusible toxin, but which have poisons either stored up in their bodies or represented in their body substance, the production of a satisfactory therapeutic serum has not yet been placed beyond doubt. It would seem that immunity towards these latter poisons can not be pushed beyond the endurance of a relatively small dose, and certain investigators have, for this reason, looked upon bactericidal functions of immune serum as the only hopeful prospect. It is now generally known, from the work of Pfeiffer and others upon typhoid and cholera bacteria, that such serum, which does not manifest, outside of the body, more than agglutinative power, does actually start bactericidal forces in the animal body, when introduced with the bacteria.

It is probable that the action of the streptococci is subject to the same laws. If this phenomenon should be found generally true of the invasive bacteria (that is, those which enter the body and multiply therein, and not simply act from some one point through absorbed toxins, as is the case with diphtheria), it follows that any serum-therapy, so-called, to be successful, must come into play either before, or immediately after the time of infection, in order that the multiplication of the bacteria may be checked before much poison has accumulated. It is probable that, between the strictly toxin-producing and the infectious bacteria, transitional species will be found for which an anti-toxin may be of some use because of the presence of traces of toxins set free by the bacteria. This hypothesis may account for the favorable results occasionally reported after the administration of streptococcus serum."

In our experience, the serum in cases of pure streptococcus infection seemed to have a beneficial influence, and, during its exhibition, local and general treatment was withheld. It is impossible to say how much value the serum per se was, in these cases; but the gradual lowering of the temperature in from 7 to 24 hours, with a corresponding reduction and steadying of the pulse, attended by a profuse perspiration and marked improvement in the subjective condition after each injection, would seem, in the absence of any other measure having been used, to have exercised a salutary influence.

The most perplexing problem we have to solve in the treatment of sepsis is, when is surgical intervention necessary? No one will question the necessity of removing the uterus and its adnexa, if they are infiltrated with foci of pus which can not be properly drained; or, of evacuating purulent collections, whether they be in the pelvis, peritoneal or pleural cavity; but when shall we operate? Those of us who have had in maternity services the opportunity of observing the varying phases of puerperal sepsis, know, that there is a tendency to recover along conservative lines, and that a very small percentage require operation. Furthermore, there is great danger of converting a localized infection into a general one by the use of intra-uterine douches and the curette. If we carefully analyze the mortality statistics of septic cases treated surgically, we can not but be impressed with this fact—that too little attention is devoted to a systematic clinical observation and the study of the various forms of sepsis. What is needed, is greater care in the study of the differential diagnosis. Bacteriology and pathology are gradually adding to our knowledge in this direction. We know that the streptococcus is the most virulent and frequent variety, and when it spreads beyond the genital tract, it does so by way of the lymphatics or veins, or both. We also know that the peritonitis which follows is primary, but that the tubes and ovaries are only affected secondarily, if at all. On the other hand, gonorrheal infection spreads by continuity of the mucous membrane and invades the tubes and ovaries primarily, while the peritoneum is involved secondarily. Staphylococcus, colon, and other pathogenic organisms, act in a similar manner to the streptococcus but in a milder degree. However, the clinical features differ. In an infection by the streptococcus the pulse rate is apt to be rapid and out of relative proportion to the rise of temperature, and the constitutional symptoms are usually well marked. On the contrary, in staphylococcus, colon, gonorrheal and saprophytic infection, the temperature may at times be high but the pulse rate is relatively lower.

In conclusion, then, the treatment of sepsis will depend upon the skill and judgment of the physician and the condition of the patient. It would not be justifiable to open the abdomen without some physical reason. The different forms of sepsis should be thoroughly understood, for an operation will hardly be required except in pathogenic infection. When the operation is performed early many organs will be needlessly sacrificed, and if performed late, the mortality will be increased. When there is continued fever with increasing physical signs, the operation is permissible; without the latter, general symptoms would indicate systemic infection and surgical measures can only hasten the end.

THE INDICATIONS AND CONTRA-INDICATIONS FOR THE USE OF THE CURETTE IN OBSTETRIC PRACTICE.*

HENRY D. FRY, M.D.
WASHINGTON, D. C.

The curette is a valuable instrument, in the hands of the obstetrician as well as the gynecologist. The indications and contra-indications for its employment are less understood in the practice of the former than of the latter, and much harm has resulted from its indiscriminate use.

In the earlier days of antiseptic midwifery puerperal fever was fought by active intra-uterine treatment, curettage and irrigation, without selection of cases. Even to-day, too little attention is paid to a consideration of the subject, and while the curette is valuable in one class of these cases, it is equally injurious in another.

The object of this paper is to bring out the experiences of the members of the Section; to break away from the old routine custom of using the instrument, and to point out clearly in what class of cases to use, and in what class to discard, the instrument.

We must bear in mind that it is employed in place of, and as a poor substitute for, the finger to remove foreign substances from the uterine cavity, as pieces of placental tissue, retained portions of membranes, blood clots, etc. In abortion, when the cervix can not be dilated sufficiently to pass the finger the curette must be used as a substitute; and again, when the expulsion of the product of conception is in the later months, the finger is unable to reach the fundus uteri. The indications for its employment to remove retained products of conception and blood clots are clear. The complications following abortion and miscarriage are almost invariably due to the retention of some part of the ovum. This is manifested by hemorrhage or fever, one or both. The hemorrhage may be coincident with the casting off of the ovum or some part of it, or it may continue afterward uninterruptedly or in recurrent attacks. *Decomposition* of the retained tissue accompanied by a foul odor to the discharge and febrile reaction is another complication. There is no question of doubt regarding the indications for the use of the curette in these cases. The removal of the offending material promptly stops the hemorrhage or fever.

Unfortunately, the treatment of incomplete abortion and miscarriage is too often expectant. Indifference on the part of the practitioner or a desire to consider the case unimportant leads to a neglect of radical treatment. Again, in many cases, a let-alone policy is followed because the general practitioner, to whom a large share of this work falls, modestly considers himself unequal to the emergency. These cases come under his care so often in the course of his daily practice, it is his duty to familiarize himself with the method of treatment necessary.

---

* Read at the Fifty-second Annual Meeting of the American Medical Association, in the Section on Obstetrics and Diseases of Women, and approved for publication by the Executive Committee of the Section: Drs. A. H. Cordier, W. E. B. Davis and Henry P. Newman.

In incomplete abortion and miscarriage when the cervical canal is sufficiently dilated, the finger is used to clean out the uterus. In most cases the patient should be thoroughly etherized, the uterus depressed with one hand on the fundus, the other hand inserted into the vagina and one or two fingers passed into the cavity of the uterus. Retained and attached portions of placental tissue are removed, a hot intra-uterine injection given of sterilized salt or antiseptic solution. If the uterus is thus cleaned out all hemorrhage is checked and the case pursues an uninterrupted convalescence.

If the case be not one suitable for this simple method of treatment, curettage may be preceded by a short preliminary treatment with the tampon, in hopes the uterus may expel its contents. Failing to do so in twenty-four or thirty-six hours, the curette should be used, preceded generally by a rapid dilatation of the cervix. Except under anesthesia, the operation can not be done satisfactorily. Asepsis is a necessary part of the technique. During curettage the removal of blood clots which plug the uterine sinuses is frequently accompanied by severe bleeding.

The hot intra-uterine douche or gauze tamponade of the uterus will be necessary. The gauze should be removed in twenty-four hours and the uterus washed out with a hot sterile douche. Rest in bed and hot vaginal douches will complete the course of treatment.

We have dealt with the treatment of incomplete abortion and miscarriage with hemorrhage and fever. The fever is due to the absorption of ptomains produced by the action of the bacillus of putrefaction upon the foreign matter contained in the cavum uteri. The removal of the offending mass with the curette gives results that are all one can wish. The good effect that follows the treatment in these cases has led to its abuse in fever after childbirth.

In cases of criminal interference with pregnancy we often have to deal with a different and more serious infective agent than the saprophytic germ. Fever is now, unfortunately, too often due to streptococcic infection. Under these circumstances, the indications for curettage are similar to those met with after childbirth and we will consider the two together. Whereas great benefit is derived, as we have already seen, by the use of the curette in removing material acted upon by the bacillus of decomposition, on the contrary, harm will follow its use when the infection is streptococcic. By use of the curette it is impossible to get rid of streptococci. Nature makes a noble and often successful resistance by throwing out a protective zone of inflammatory tissue at the point of infection. Leucocytes swarm to her assistance and take up their burden of the fight to resist the aggressive germs.

Now, what does the curette do in these cases? It simply breaks down the earthworks, scatters the defenders and opens a door of entrance to the invaders. The infection, instead of being localized is made general. The clinical history bears out the statement. Cases of streptococcic infection invariably get worse after curettage. A chill shows systemic infection; the symptoms are all aggravated, and more cases end fatally than when the curette is not employed.

Hence, it is of prime importance in a given case to ascertain the nature of the infective agent, or agents, before resorting to the curette. The foul discharge that accompanies the action of the bacillus of putrefaction is a safe guide to indicate the use of the instrument. In the absence of that sign the indication is not clear, and we must rely upon the culture test.

The culture is taken by introducing a sterile glass tube into the uterus and with a syringe attached to the other end, the uterine discharge is sucked into the tube. It is then placed in a culture tube containing agar-agar. The growth of the organism will demonstrate its character in twenty-four hours. To be of value, the culture must be taken with the strictest detail to aseptic work. After having taken the culture, the uterus is thoroughly douched out with sterile salt solution and no further local treatment instituted for twenty-four hours, or until the result of the culture is known. If it prove to be streptococcic the curette is contra-indicated.

In another class of cases the curette does harm. Infection may exist in some laceration of the vulva, vagina, or more often, the cervix. The cavity of the uterus is not involved. The use of the instrument under these circumstances is uncalled for and will likely spread the infection into the uterus.

At the risk of being found guilty of repetition, we will consider the indications and contra-indications for the use of the curette by taking a hypothetical case. A woman having given birth to an infant, in three or four days afterward suffers from a fever, which is preceded or not by a chill. All the usual symptoms of puerperal fever are present. Shall we or shall we not curette? Believing that the curette does harm in some of these cases we must look for clear indications for its use. First carefully inspect the external genitals, the vagina and cervix. In not a small proportion of cases the door of entrance for the germs is located in one or other of these parts, and in such it is evident the curette would do harm by carrying the infection into the uterine cavity. If, on the contrary, the examination be negative, and the indications point to intra-uterine infection, the next point to decide is the character of the infection. The presence of a foul odor to the discharge would justify the careful use of the curette. A culture should then be made of the discharge and the cavity thoroughly injected with hot sterile water or salt solution. In the absence of foul discharge the curettage should be omitted, but the culture taken and the preliminary injection employed. After twenty-four hours the culture growth will demonstrate the nature of the infection. If other than saprophytic the curette must not be used.

Streptococci are the most common and serious germs encountered in puerperal infection, but the same rule regarding the use of the curette applies to others, such as the staphylococcus, gonococcus, colon bacillus, etc.

In obtaining the culture the external parts should be cleaned and washed in bichlorid, the hands and instruments must be clean, the cervix exposed and held with a double tenaculum or bullet-forceps. The sterile glass tube is passed into the cavity of the uterus, a syringe attached to the other end with a short rubber tubing and some of the fluid drawn into it. The cotton plug is removed from a culture tube containing the agar-

agar and the discharge inserted. During the twelve or twenty-four hours required for the growth of the organism the case is treated on general principles.

The clinical history of the case presented, as well as the history of confinement, aid materially in making the diagnosis before the bacteriologic test is available.

A final word of caution to the inexperienced may not be out of place, regarding the danger of using the curette in a septic uterus. The walls are easily punctured or torn, and any approach to force is unwarranted.

A CASE OF STREPTOCOCCUS INFECTION FOLLOWING LABOR—OPERATION AND RECOVERY.[*]

WILLIAM H. HUMISTON, M.D.

Associate Professor Gynecology in the Medical Department of Western Reserve University; Gynecologist-in-Chief to St. Vincent's Charity Hospital; Consulting Gynecologist to the City Hospital, Etc.

CLEVELAND, OHIO.

A primipara, aged 23 years, was delivered with forceps after six hours in labor, on Nov. 26, 1900. On the third day, after a slight chill, the temperature rose to 103 F. The uterine cavity was douched with a mild antiseptic solution. Failing to get a result from this procedure, the curette was employed, and thereafter daily intra-uterine douchings.

On December 5, the sixth day of the fever, I saw the case in consultation. Temperature was 100, and the pulse 120, irregular and weak. The fundus of the uterus was midway between the symphysis pubis and the umbilicus. There was no tympanites and but little tenderness of the abdomen. A deep laceration of the perineum, which had been repaired after delivery, but opened again, and the torn surfaces of the cervix (right lateral tear) were covered with a grayish slough, which in appearance was not unlike that of diphtheric origin. There was marked cellulitis to the right of the uterus extending to the pelvic wall.

I advised an incision and drainage of this mass through the vagina. The family desired to temporize, as the patient then seemed to them to be a little better. However, on the evening of that day they reported that a sudden change for the worse had occurred following a severe chill. The temperature as recorded was 103, and the pulse-rate 160. The patient was vomiting and complained of severe pain.

She was admitted to the hospital early on the following morning. Her temperature was 104 and pulse 160, arrhythmic, irregular and of small volume. Her general appearance was that of grave toxemia. There was great abdominal distention and increased tenderness. She was having a septic diarrhea. A small quantity of urine was obtained by catheterization and found to contain granular casts and renal epithelium.

After thorough cleansing of the vagina and the uterine cavity, the latter was packed with iodoform gauze. A very free incision was then made through the posterior vaginal vault, and the dissection carried upward and between the folds of the right broad ligament. There were several small foci of beginning softening in this area of cellulitis, but no pus formation as yet. When the pouch of Douglas was opened a large quantity of bloody serum, streaked with whitish flocculi, escaped. Examination of the Fallopian tubes showed that they were not involved in the process. After carefully drying the parts, two small pieces of rubber tubing were used for draining the cul-de-sac and the broad ligament. Iodoform gauze, rinsed in hot salt solution, was used to pack the cavities. During the operation two quarts of normal salt solution were injected under a breast.

Cultures were taken from the cervical canal and the peritoneal cavity. From the latter, growths of the streptococcus pyogenes and colon bacillus were obtained; and from the cervix, the same together with the staphylococcus pyogenes albus. Cover-slip preparations gave the same results. No diphtheria bacilli were obtained. Three drams of chloroform were used, and the patient was on the table thirty minutes. In twelve hours the temperature was 102.4, and the pulse 116.

On the third day the temperature again rose to 103.2 and the pulse 130. On removing the vaginal dressings an abscess containing one and one-half drams of pus was discovered in the vaginal wall. After this was opened the patient progressed rapidly. On the fifth day the temperature was normal and the pulse remained below 100.

With the Fallopian tubes apparently normal, the infection of the peritoneum must have occurred by an extension from the cellulitis. Even though, as in this instance, the physician may be in attendance upon cases of diphtheria and the slough may bear the characteristic appearance of diphtheric exudate, bacteriologic investigation is necessary to determine its causation. The absence of shock and the rapid reaction is not due alone to the use of a large quantity of salt solution, but to the rapidity and the ease with which these conditions can be cared for by the vaginal method. There is no necessity for complete narcosis, and the limited amount of the anesthetic required minimizes the dangers of unfortunate results.

An examination of the pelvis six months after the operation reveals a very satisfactory state. The obliteration of the cul-de-sac has made the uterus somewhat immobile, but this can be largely overcome by massage and judicious use of tampons. The right broad ligament, together with the uterine adnexa of this side, are practically in a normal condition.

I have reported this particular case, 1, because of its gravity; 2, because of the happy results; 3, because of its gravity and the results obtained, the report may stimulate others to use the vaginal route in preference to the abdominal. I have not yet lost a case of puerperal sepsis where the septic foci were confined to the pelvis since my adoption of the vaginal method.

DISCUSSION ON PAPERS OF DRS. ZINKE, PORTER, MORAN, FRY AND HUMISTON.

DR. PHILANDER A. HARRIS, Paterson, N. J.—There is no reason why anyone should differ essentially from the points brought out in these papers. When I and others of my age studied medicine, hospitals were regarded as death-traps, and for long afterward we looked askance at maternity hospitals; conditions have changed since then, and now a well-ordered hospital is the very safest place for a woman during her confinement, especially when any instrumental or manual aid is necessary. The question as to what extent women may be taken from their homes to the hospital is a matter for consideration. It has its ethical side.

Dr. Fry's statement that the uterus may get into a condition where it no longer takes up an infection, is very true. I believe the endometrium usually acquires this immune condition in a few days, and that the toxemias and other evidences and miscarriage is too often expectant. Indifference on the part of the practitioner or a desire to consider the case unimportant leads to a neglect of radical treatment. Again, in many cases, a let-alone policy is followed because the general practitioner, to whom a large share of this work falls, modestly considers himself unequal to the emergency. These cases come under his care so often in the course of his daily practice, it is his duty to familiarize himself with the method of treatment necessary.

DISCUSSION ON PAPERS OF DRS. ZINKE, PORTER, MORAN, FRY AND HUMISTON.

Dr. Philander A. Harris, Paterson, N. J.—There is no reason why anyone should differ essentially from the points brought out in these *papers*. When I and others of my age studied *medicine*, hospitals were regarded as death-traps, and for long afterward we looked askance at maternity hospitals; conditions have changed since then, and now a well-ordered hospital is the very safest place for a woman during her confinement, especially *when* any instrumental or manual aid is necessary. The question as to what extent women may be taken from their homes to the hospital is a matter for consideration. It has its ethical side.

Dr. Fry's statement that the uterus *may get into* a condition where it no longer takes up an infection, is very true. I believe the endometrium usually acquires [illegible] une condition in a few days, and that the toxemias [illegible] dences of a continued infection are due to extensions from the primary infection to other parts. If, therefore, we employ a curette to field what Nature has already defertilized, or strong disinfectants, or anything which will destroy the vitality of the tissue, then we may have a local reinfection. The matter of curetting the uterus under these conditions is a very serious and important one, and I wish to endorse the work of Dr. Fry. I have worked mainly along the lines laid down by him, which we all ought to follow. In certain instances physicians who have asked me to see cases of puerperal fever with them, have looked rather disappointed when I have refused to curette the uterus. In regard to the vaginal section, I stand entirely with the last speaker, and also with many others here who follow the example of Pryor, of New York. I do not believe it does any harm. Vaginal section may reveal pus when the qualities of fluctuation or induration are absent.

---

[*] Read at the Fifty-second Annual Meeting of the American Medical Association, in the Section on Obstetrics and Diseases of Women, and approved for publication by the Executive Committee of the Section: Drs. A. H. Cordier, W. E. B. Davis and Henry P. Newman.

Dr. Miles F. Porter, Fort Wayne, Ind.—Puerperal infection is a term that covers a multitude of pathologic conditions, and we can not speak about its successful treatment until we first determine the form of infection we are endeavoring to treat. It occurs to me that the loose way in which we have been talking about vaginal versus abdominal section in puerperal infection, has led to a great deal of practice which is not of the best character. My own impression is in accord with the writer of the paper on the use and abuse of the curette in cases of puerperal infection of the endometrium. Vaginal section has a place if there is in the pelvis a localized accumulation of infectious material—a localized peritonitis. On the other hand, in the treatment of a case of progressive septicemia, whether puerperal or not, operations are seldom beneficial and usually harmful. There are so many things to say, that we might prolong the discussion indefinitely, but the point I want to make is that puerperal infection covers such a multitude of conditions that to speak of its treatment by any one method is irrational.

Dr. A. B. Cates, Minneapolis—I think that the profession does not appreciate the progress made by our surgeons in the use of the rubber gloves. For the last two years I have been using them in nearly all my cases of confinement, and have found that the lying-in period has been greatly improved. It is rare, indeed, for sepsis to occur. The vulva should also be carefully cleansed, and the patient must be instructed to keep her hands away from the external genital organs. This is especially important, as sepsis is frequently conveyed in that way. In a case of sepsis, treatment should be directed to the place from which absorption is taking place. Sepsis will frequently occur from absorption from the perineum or from a lacerated cervix. These are the most common foci of infection. If the infection extends, as it frequently does, we most commonly have an endometritis. If this occurs it is desirable to ascertain the character of the bacteria present. We have been told that the streptococcus should be let alone, that we are not to curette in a case of streptococcus infection. That is good advice. I think that the suggestion of Dr. Williams, of Johns Hopkins, is a good one, that if on examination of the interior of the uterus we find a smooth surface, it is a streptococcic infection; if it is a rough surface it is usually a mixed infection or a sapremia. If you have a sapremia there is no question but what you need the curette and intra-uterine douches. I believe that with proper precautions, we can not, as a rule, do very serious harm with intra-uterine douches in any case except a streptococcus infection.

The use of ergot has not been mentioned by any one in this connection. I think more stress ought to be laid upon the use of ergot in the earlier stages of the lying-in period. It not only tends to contract the uterus, but also to prevent absorption from the lymphatics.

Dr. W. O. Henry, Omaha, Neb.—I think we talk too much of ideal conditions. The large majority of women confined are absolutely outside of the reach of a prompt bacteriological examination. Theoretically, Dr. Fry's paper is all right, but practically it can not be followed at the present time by the large majority of practitioners. I fully endorse his investigation; but as in the majority of instances it is impossible to determine quickly the nature of the bacteria present, we ought to agree on a line of treatment that every man can use safely, readily and successfully. I am confident that the man who knows how to use the curette following abortions or normal labor with infection, can use it safely. He will never do any harm. It matters not what your infection is, nor whether it comes from the endometrium or a torn perineum or a lacerated cervix or a tear in the vagina; every raw surface should be absolutely and thoroughly cleansed with the curette. If you were to look inside the uterus following a labor, you would find there a large mass of lymphoid-like tissue which is gradually breaking down and which in part keeps up the flow following confinement. If infection has started there, the sooner you clean out that uterus and get rid of all this tissue the better it is for your patient. It has been my practice for several years to clean out the uterus thoroughly, clean off every raw surface in the vagina, cervix or vulva with a sharp curette; then I put on absolutely pure carbolic acid, after which a little alcohol can be used to counteract the acid. I do not use it as a routine practice, but it will do no harm. The acid is a mild caustic and kills every germ within reach. If you find a little fluctuation or infiltration back of the uterus, make a vaginal incision and drain. Sometimes you get pus and sometimes a bloody fluid. The vaginal section is preferable to opening the abdomen, which I believe is always wrong in acute cases and will cause you to lose a large portion of your patients.

Dr. Edwin Ricketts, Cincinnati—Much has been said as to the recognition of these germs after they have once caused the infection. I wish to say a few words on the line of prevention. I think since the appearance of the lady physicians among us, we have a great prophylactic factor which will do away with the midwife. When we, as a profession, recognize this fact and extend our aid to the recognized lady physicians, rather than extending it to the midwife, we are going to do a great amount of good in the prevention of many cases of sepsis. I recall an instance which occurred a short time ago in which a midwife was responsible for seven cases of infection, four of whom died. When we see how these cases are handled it is enough to cause consternation. You can read between the lines of every paper read on this subject this afternoon and it is against this thing of not being clean, and that in turn is against the midwife. I am in full accord with the statement made by Dr. Zinke that the birth of a child is a surgical procedure. Treat that uterus as you would a broken bone. The time is coming when the recently delivered uterus will be carefully packed with gauze and it will be one of the greatest steps toward dealing with such infection that we will have at our command.

Dr. C. A. Dannaker, Kansas City, Mo.—Modern civilization has produced an environment which does not help the work of the obstetrician. A great majority of people live in flats which are not conducive to carrying out proper aseptic precautions. A large number of people are not prepared by their environment to become mothers. The maternity hospital fills a long-felt want. The parturient can be taken care of there with less expense, better surroundings and better results than would obtain in the above surroundings. The maternity hospital is the safest place for this work.

In regard to the pathological germs, which the gentleman said mean so much, it is plain dirt. How many of us go to the bedside of a maternity case after washing our hands? Ask the nurse or attendant to bring a basin of water so that whenever we make an examination we can wash our hands. How many of you give an enema before labor begins so that the rectum is clean and so that you will not introduce anything into the vagina with your finger? How many of us are extravagant in the use of cotton beneath the vulva to catch the debris? So many of us think so little of these little things that make our patient comfortable.

As to the position of the mother, it is impossible in private families to bring the patient around to the side of the bed, except in instrumental interference. That can only be done in hospitals. We should think of all these things in time, as much depends on doing these little things right.

Dr. J. Wesley Bovee, Washington, D. C.—I notice that there was some applause following Dr. Henry's statement as to the use of carbolic acid. There is no question that there is this very zone present mentioned by the essayist which is outside of material that is dangerous. This material Dr. Henry would remove with the curette and so would the rest of us if we could get it out alone, but the danger is that we might get into the zone beyond and thus open up the avenues for infection. It is impossible to remove all of the pathological organisms with either the curette or carbolic acid. As soon as you put the acid in it is diluted and thus gives an opportunity for the development of those bacteria that are left. The bacteria have a good pabulum to work on and avenues for spreading in the surrounding tissues. You must also remember a number of cases on record of carbolic acid poisoning resulting from its application to the uterus, and many other cases of dangerous toxic symptoms which, however, recover.

I am not willing to introduce my hand into the vagina of a woman who has been delivered two or three days previously. I do not consider the danger of my hand, but the danger of not getting a thoroughly sterile vulva from which infection can easily be carried into the uterus. This applies to the gloved hand as well as to the bare one.

I do not know how the last speaker expects to get rid of the danger of infection by washing out the rectum. It is perfectly proper to have an empty rectum during delivery, but he must not imagine that he has escaped the danger of infection by cleaning it out. One point of great value is to keep applied to the vulva an antiseptic solution. In my practice a pledget of sterile cotton is soaked in lysol or bichlorid solution and placed against the vulva, the vulva being spread open when the cotton is put there. That is kept there all during labor until the head of the child throws it off. It is also kept on for a number of days after the delivery. This is of extreme importance because it tends to asepticize the vulva.

Dr. W. D. Porter, Cincinnati—The use of intra-uterine douches is a procedure universally recommended by all authorities. They specify, as do the papers we have just heard, that such a douche shall be hot. Some seven or eight years ago a writer in the *Philadelphia Medical Journal* said that the chill which occasionally follows the use of the hot douche was due to the fact that the heat had the effect of contracting the vessels and of diminishing the drainage for a short time. The chill is the direct result of this failure of elimination. Since reading that article I have never used a hot intra-uterine douche and no chills have followed. I think it is important that the temperature of the douche be no higher than the body temperature.

Dr. Moran, in closing—My paper should have been entitled the "Prophylaxis and the Treatment of Puerperal Sepsis." It has been the custom in the Columbia Hospital at Washington to invariably use rubber gloves. Whoever examines the patient, is required to use the gloves. We have been doing that for the last year.

The Egyptian Medical Congress will be held under the patronage of the Khedive at Cairo, from December 10 to 14, 1902, under the presidency of Dr. Abbate Pacha. The honorary presidents are Dr. Ibrahim Pacha Hassan, Dr. Pinching and Dr. Ruffer. The general secretary is Dr. Voronoff. The work of the Congress will be divided among three sections, as follows: 1, Medical sciences, presided over by Dr. Comanos Pacha; 2, Surgical Sciences, presided over by Dr. H. Milton; and 3, Ophthalmology, presided over by Dr. Mohammed Bey Eloui. The program of the Congress will include discussions on affections especially rife in Egypt, such as bilharzia, ankylostomiasis, bilious fever, abscess of the liver, etc. Special attention will be given to questions relative to the epidemics which for some years past have regularly visited Egypt, and the prophylactic measures to be taken against them.—*Brit. Med. Jour.*

REMARKS ON SPINAL SURGERY, WITH ILLUSTRATIVE CASES.*

ANDREW J. McCOSH, M.D.

NEW YORK CITY.

(Concluded from p. 573.)

TUMORS.

Operations for spinal have generally been more satisfactory than those for cerebral tumors and offer better promise for future operative successes. There are good reasons for this. In cranial surgery the diagnosis, both as to the nature and location of the lesion, is less accurate; the lesion is often inaccessible to the surgeon and much permanent damage has often been done to the brain prior to the operation.

The symptoms of tumors of the cord are generally well marked and their location, at least within a certain limit, can be usually accurately determined. When studied with the history of the case the lancinating pains, the muscular paralyses and contractures, the altered reflexes, and the disturbances of sensation, lead us to a comparatively certain diagnosis and one is much less apt to meet with surprises than has been the case doubtless with most of us when operating for cerebral tumors. As already stated the location can generally be definitely determined. Uncertainty, however, always exists as regards the character of the growth and the structures involved.

Concerning the character of the lesion it is probable that tubercular masses, whether of bone or granulation tissue, are among the most frequent causes of pressure of the cord. In the present paper, however, this class of cases is not considered.

Of spinal tumors proper the most common are unfortunately those of malignant growth. The prognosis of these must of course always be bad, though not hopeless, as is shown by the permanent recovery of a patient from whose cord a sarcoma was removed by Davies Colley (Clin. Soc., London, 1892). Even if permanent cure can not be effected temporary relief for at least many months may be accomplished. As an example of this let me narrate the following cases, one of whom at the end of a year after operation is apparently perfectly well.

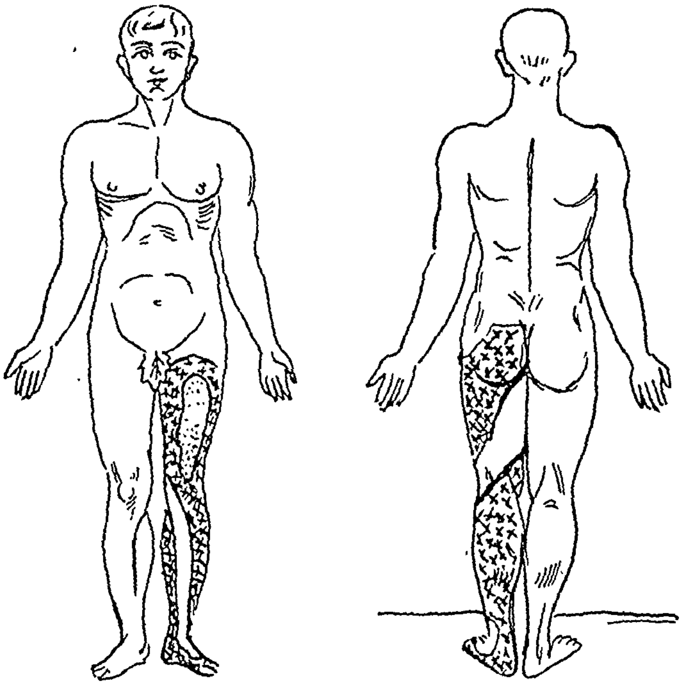
Case 11.—Sarcoma of upper Lumbar Cord; Removal; Recovery: E. K., male, aged 39, has good family history. For many years alcoholic. No venereal or traumatic history. In December, 1898, he noticed a lancinating pain shooting down the posterior part of his right thigh to the back of the knee. It was spasmodic in character. He was treated for sciatica. It continued intermittently; in July, 1899, he experienced pain in the sacral region, right buttock and posterior thigh. He went to the country, where he spent the summer and improved so much that he was able to remain at his work from October till January, 1900, when the pain became so severe that he was obliged to remain most of the day on the sofa. About this time he came to see me, complaining of what he termed sciatica, mainly on the left side. He also complained of pain in the lower lumbar region where there was also some tenderness to pressure, especially to the left. There appeared to be some stiffness in the lower part of the spine; there was no paralysis, no anesthesia; knee-jerks were normal. I suspected at the time pressure on the cord but was rather inclined to favor tubercular disease of the bone. He drifted away from my care. He was treated with a brace, mercurial inunctions, iodids, etc., without benefit. In fact his symptoms gradually progressed and after the end of April his pain became especially severe, extending down the posterior surface of the thighs and legs to the feet. About May 1 he noticed numbness, which extended over the area where later anesthesia (shown in the diagram) appeared on the posterior and outer surface of the left thigh, leg and foot. At the same time he noticed decided weakness of the left leg.

---

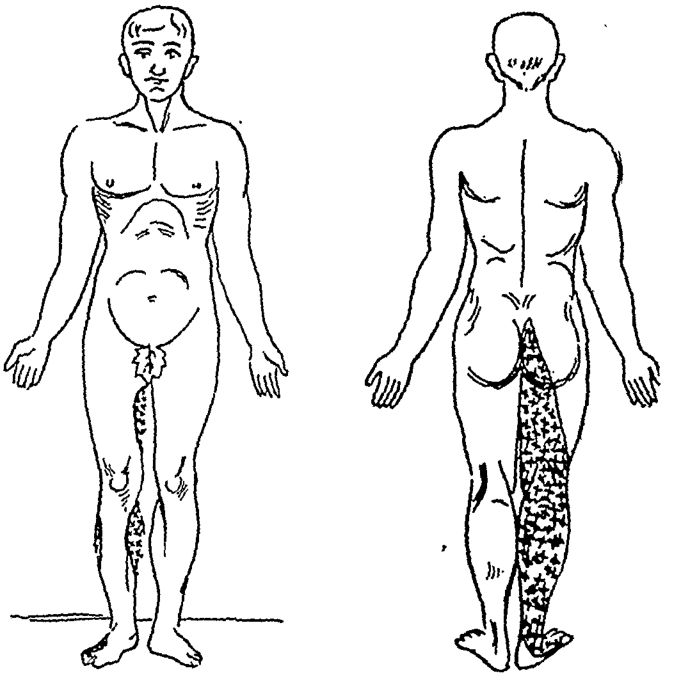
* Read at the Fifty-second Annual Meeting of the American Medical Association, in the Section on Surgery and Anatomy, and approved for publication by the Executive Committee of the Section: Drs. W. J. Mayo, H. O. Walker and A. J. Ochsner.

After consultation with Dr. Pease Bailey the diagnosis of tumor of the cord at the upper part of the cauda equina was made, and he was sent to the hospital on May 15 for operation. There was pain and tenderness along the lower spine; pressure at this point caused a burning sensation along the posterior and outer aspect of the left thigh and leg. There was partial paralysis of the muscles of the left thigh and leg with some atrophy, the left thigh measuring two inches less than the right. The left patella reflex was entirely absent. There was no ankle clonus; no priapism.

Operation May 22, 1900; gas and ether. An incision was made from the eleventh dorsal to the second lumbar spines; the spines and laminæ of the twelfth dorsal, first and second lumbar vertebræ were removed. Through the dura was seen a bluish substance. It was opened through the extent of the incision. No cord could be seen, but the canal seemed occupied by a bluish, watery, granulation-like mass which extended from the lower border of the twelfth dorsal vertebra to and somewhat below the upper border of the third lumbar vertebra. On pricking the tumor considerable greenish fluid escaped. At the upper part of the twelfth dorsal vertebra the normal cord was seen, and when followed downward was found displaced to the right and anterior part of the vertebral canal, where it was first exposed after removal of the tumor, which was done by a sharp spoon. The tumor, which was soft and vascular, extended well around the lateral surfaces of the cord. It was about two and a half inches in length, a half to two-thirds of an inch in thickness. All that was seen well around to the sides of the cord was carefully scraped away, as was also the bone. The hemorrhage was trifling. The dura was sutured, and also the wound. A small gauze drain being inserted. Shock was very slight and the patient made a perfect recovery from the operation. Previous to the operation for several weeks he had been using three to five grains of morphin daily, after the operation he required but one hypodermic of a quarter grain. His pain immediately ceased and on the day following he declared that he was more comfortable than he had been for months. He remained in the hospital for thirty days, during which time he gained 22 pounds. During this time he suffered no pain whatever; sensation gradually increased in the anesthetic area and when he left the hospital there was a slight knee-jerk in the right knee.



CASE 11.—Tumor. The small crossed lines represent partial, the dotted complete anesthesia.

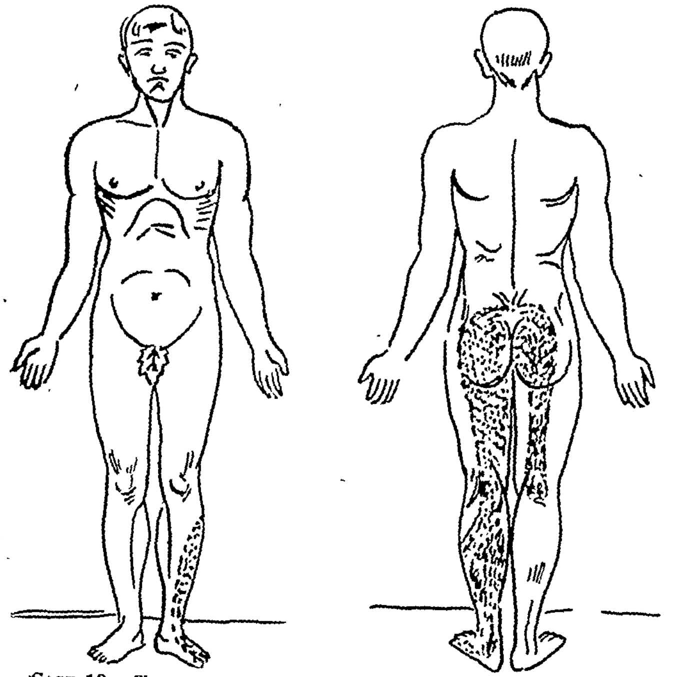


CASE 12.—Tumor. Small crosses indicate area of partial anesthesia to touch, pain and temperature. *Pain is also referred to this area.*

He continued to improve and on examination in September, 1900, sensation was found normal; the left patella reflex was completely restored; the left thigh measured but an inch and a half less than the right. He had gained 35 pounds in weight since the operation and said he was in perfect health. During the winter until May 25 he has remained at work lifting heavy printing plates weighing from 20 to 60 pounds from a table to a shelf above his head. He says that he experiences no stiffness or weakness in his back, and though he feels tired at night he feels well. While there is still a prospect of recurrence of the growth the man has been restored to perfect health and comfort for more than a year.

CASE 12.—Sarcoma of Lumbar Cord; Removal; Recovery; P. D., male, aged 46, had always been a healthy man of good habits, with no venereal or traumatic history. About Christmas, 1900, he began to feel some pain on the outer side of his ankles. About the middle of February he compained of considerable pain shooting down the posterior part of the right thigh and leg as far as the outer ankle. It increased rapidly, and by March 1 was so severe that he was obliged to give up work and go to bed. In the middle of March the pain began to shoot from the sacral region around towards the right groin, the glans penis, testicles and inner side of right thigh. He also had pain on defecation, and when his bladder was full. Micturition at times was difficult, and he was markedly constipated. He was brought to the hospital by ambulance on May 20, having fallen down in a severe paroxysm of pain. During a week's observation in the hospital, the pain, shooting from the sacral region across the right buttock and down the posterior surface of the right thigh and leg, was very severe. There was considerable loss of power in the right thigh and leg. He could not stand up, but thought this was partially due to his pain. There was an area of partial anesthesia, at times seemingly complete to both touch, temperature and pain along the right posterior thigh, leg, and over the outer side of the foot. On his buttock above and internal to this there was a narrow line of hyperesthesia. Both patella reflexes, but especially the right, were feeble. Jarring of the body did not cause pain, though it was somewhat increased on motion and there was some tenderness to pressure in the lower lumber region. In four weeks he had lost 30 pounds in weight.

After consultation with Dr. Northrup, the diagnosis was made of tumor probably malignant in the neighborhood of the third lumbar vertebra. Operation, May 28, 1901; gas and ether. An incision was made from the fifth to the first lumbar spines. The spines and laminæ of the second, third and fourth lumbar vertebræ were removed. There was seen lying on the dura a dark-red, purplish, vascular granulation-like mass, completely hiding the dura except at the upper and lower extremities of the wound. The tumor somewhat irregular, about two and a half inches in length, was spread out more than half way around the cord. It varied in thickness between a quarter and a half an inch. It was removed by a sharp spoon, and in order to reach its lateral projections the cord (cauda equina) was raised from its bed and almost lifted out of the canal. The tumor was apparently removed, but doubtless it was not thoroughly eradicated. It extended from the upper border of the fifth lumbar vertebra as high as the middle of the second lumbar vertebra. In its removal the dura was freely opened and in part removed. The nerves forming the cauda equina were considerably contused and somewhat lacerated. The dura could not be closed. The wound was sutured, with the exception of the gauze drain.



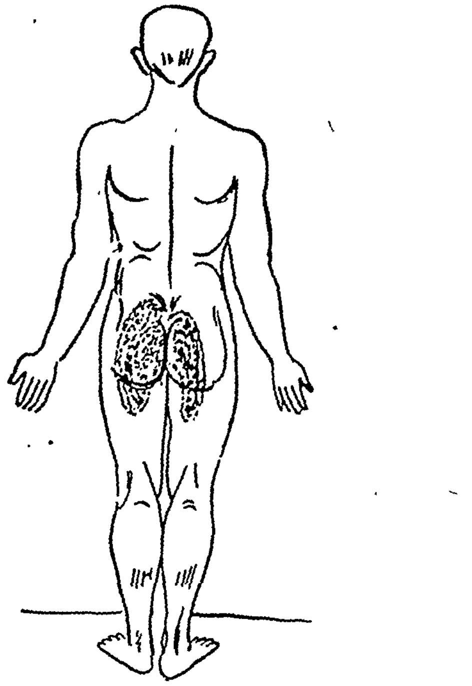
Case 13.—Tumor. Area of partial anesthesia to heat, Nov. 10, four days before operation.

Very slight shock followed the operation. The man suffered no pain, in fact when he recovered from the anesthetic he declared he was more comfortable than he had been for three months. There were no muscular twitchings and no increase in his paralyses.

The gauze drain was removed at the end of thirty-six hours. A considerable amount of cerebrospinal fluid continued to escape from the wound for four weeks, and then gradually ceased. The anesthetic area remained unchanged for five days, when slight improvement was noticed, which has continued.

Case 13.—Sarcoma involving Cord, Bone, and Muscles in Lumbar Region; Operation; Temporary Improvement, followed by Death: H. M., female, married, aged 30, is mother of four children. No venereal or traumatic history. Moderate drinker but always enjoyed good health. About the middle of September patient began to experience in the left foot and leg the sensation of pins and needles being stuck into the skin. This was most felt on the outer surface of the leg just above the ankle. It caused the patient considerable pain; during the next two weeks these sensations gradually extended upwards toward the trunk. The parts affected felt numb, less discomfort was felt when walking, than when at rest. About the middle of October the pain became less severe but the patient found she had lost the power to use her left lower extremity in walking or standing. At this time she still had control of her bladder and rectum.

On October 22 she was admitted to the medical side of the hospital; her general condition was then good; there was partial paralysis of the left leg, causing marked drop-foot. The patella reflex on the left side was completely lost, on the right markedly diminished. Sensation was normal to pain and touch. Several large blebs were present on the left foot. The circumference of the left leg was four inches smaller than that of the right. There was a beginning bed-sore over the sacrum. The symptoms rapidly increased, she soon lost control of bladder and rectum. In two weeks the paralysis had spread to the anterior tibial muscles of the right leg, and a saddle-shaped area of anesthesia developed in the lower extremities as far as the foot on the left side and the lower third of the thigh on the right. The paralysis of the right side continued to increase and the patient began to complain of very severe pain in the small of the back, and along the hips down into the thighs. The temperature was normal and the pulse ranged between 90 and 110. The urine contained albumin, casts, and some pus. In the meantime, on the supposition that the lesion might be syphilitic, iodid of potash was administered in increasing doses.



Case 13.—Tumor. Area of partial anesthesia to heat, Nov. 26, sixteen days after operation.

The diagnosis was made of tumor, probably malignant, in the neighborhood of the second and third lumbar vertebræ. The patient was transferred to the surgical side for operation on November 13, 1900; chloroform. An incision was made from the first to the fourth lumbar spines. The muscles next the bone were found infiltrated with a spongy, very vascular growth, which infiltration was afterwards found to spread laterally for a considerable distance. The spines and laminæ of the second and third vertebræ, and probably a fourth, were more or less disintegrated and were infiltrated with the same spongy, friable, very vascular growth. Considerable masses of bone were removed, as also of the soft parts, in hopes that the pain would thus be somewhat relieved. Radical operation was out of the question and the cord which could not be distinctly recognized was infiltrated by the same new growth, as was also probably the vertebral bodies. The bleeding was severe, but was controlled by pressure. Shock was severe, but she soon rallied.

Marked improvement followed the operation. Her pain practically ceased; there was some return of sensation and to our surprise the wound healed kindly. On January 1 the patient was comparatively comfortable and was able to sit up part of the day in a chair.

The bed-sores did not heal. During February, however, all progress ceased; the patient began to grow weaker; she began to suffer pain; the paralysis increased and in March a tumor developed in the epigastric region. She gradually grew weaker and died on April 10, 1901.

In regard to the structures involved, whether the tumor arises from bone, membrane or cord, it is often impossible to determine. The bony tumor will generally be malignant or tubercular in character. In either case while an operation may not be able to remove the growth it may enable the operator to relieve, at least for a time, the pains, which are apt to be agonizing. This may be accomplished by division of appropriate nerve roots. To be of any service three roots must be divided, as the anastomosis between the sensory nerves is so perfect that the division of one or two nerve roots is practically useless for abrogation of pain.

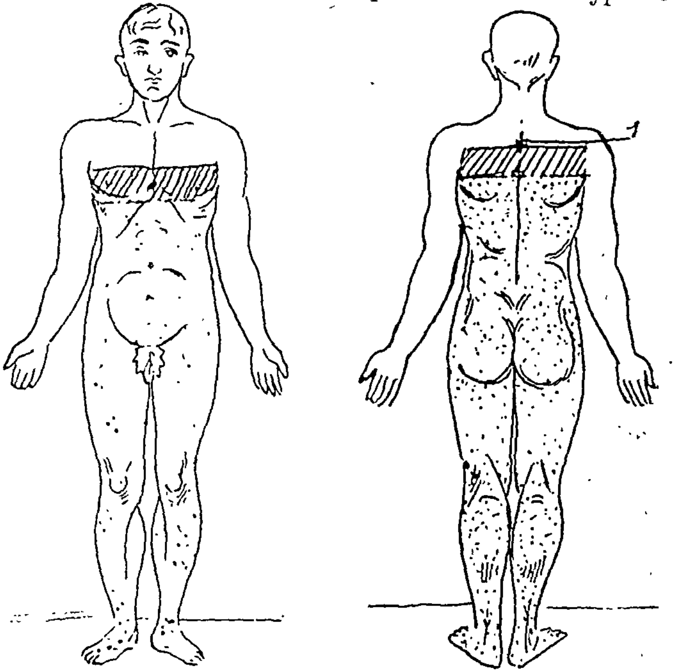
As regards the situation of the tumor relative to the cord, it may be stated that no case has yet been reported where recovery has followed the removal of an intramedullary tumor; neither has a tumor been successfully removed from the ventral side of the cord. It seems to be the rule that the higher up in the cord the tumor be situated the worse becomes the prognosis.

Provided a tumor of the cord is diagnosed, what is the surgeon's duty? Is he to operate at once on every case? Is he to wait for confirmatory symptoms, such as signs of degenerations or extension of paralyses? In regard to the first question the same principles should rule him as would were there any other organ concerned. He should ask: 1. Can the tumor be removed? 2. If irremovable can the patient be relieved by palliative operation? 3. What are the dangers of the operation? 4. What are the chances of permanent recovery? The nature of the growth—the structures involved and the damage already done to the cord are problems which as yet we are generally unable to solve, at least with certainty. Knowledge concerning the danger of operation is, however, more definite. While many cases have died as the direct result of operation and in others death has been hastened, the dangers at the present day should not be great. Certainly, a mortality directly due to operation should not be more than 10 per cent. Many of the reported cases where death followed within a week or ten days, were done years ago, when our methods were less perfect than they are to-day. Sepsis was the principal cause of death. At the present time we certainly would not expect this to occur in more than 1 or 2 per cent. of our operations. Death from shock or hemorrhage should result but rarely, certainly in not more than 5 per cent. of our cases.

Provided there is reasonable probability of the existence of a spinal tumor, and unless there be positive evidences that cure or relief is impossible, I would urge operation on every case at the very earliest possible moment. If it be postponed the chances of benefit become less with every day's delay. If no operation be done the outlook is hopeless. The result will be progressive pain, weakness and death.

Lloyd has collected 51 cases of operation for tumors of the cord, with a mortality of about 10 per cent.; 31 per cent. of these cases recovered. My own operations number 6. Of these none died as the result of operation. One patient at the end of more than a year is well; another at the end of two months. Two died from sarcoma of other organs. One died at the end of two months from sepsis due to bed-sores and cystitis.[2]

The possibility that the tumor is syphilitic, in the nature of a gumma, unfortunately, must be considered. I say "unfortunately," for the delay caused by this possibility has been responsible for the loss of many lives. It is rarely that a case of spinal tumor is not subjected to this treatment, which involves a delay of many weeks. Of the tumor cases which I have seen, with one exception, every patient has been subjected to antisyphilitic treatment. In one of my cases at least this treatment, or rather the delay, necessary for its test was largely responsible for the patient's death and I feel sure that most of you will recall similar cases. If a patient gives a syphilitic history it is certainly proper that the specifics should be tried for a reasonable time, but when no such history is given it seems to me most undesirable to soak the patient with mercury and iodid, and in the mean time allow bed-sores and other complications to develop, which render operative interference almost hopeless. If pressure due to syphilis were common there might be some excuse for trying to relieve it by medication, but as gummata sufficient to produce the symptoms of pressure resembling those of tumor are very rare, it seems to me that it is generally wiser and safer practice, where there is lack of evidence of syphilis, to give the patient the benefits of an operation. Death which resulted in the following case may largely be attributed to such delay.



Case 14.—Oblique lines indicate band of partial anesthesia. Dotted parts indicate area of complete anesthesia to touch, pain and temperature.

Case 14.—Fibroma of lower Cervical Cord; Operation; Removal; Operative Recovery; Death in 43 days: Mrs. W., aged 37, had been a comparatively well woman until January, 1900, when she began to complain of some obscure abdominal pain. There was no history of syphilis or traumatism. In March or April, 1900, she began to complain of severe neuralgic pain, shooting around the chest just below the left breast. Soon after this she noticed numbness of her left leg and there was slight increase of both patellar reflexes. In the summer of 1900, her lower extremities became more or less paralyzed, and in August she began to lose control over her bladder and rectum. In September the paralyses in her legs became complete. The patellar reflexes became more exaggerated and any irritation to her body produced violent muscular spasms in her lower extremities. The neuralgic pain around the left side of the chest became very severe. Anesthesia of the body as high as a line drawn at the fifth or sixth dorsal nerve became complete.

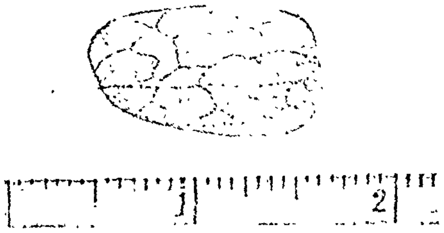
---

[2] One, Case 1, reported as lipoma, should probably not be considered in this connection.

The patient was treated for weeks and months with mercury and iodid of potash. Her symptoms during the summer varied somewhat, being for weeks at a time of milder type, but in the autumn they became rapidly worse. In the meantime, due to the delay necessitated by the employment of antisyphilitic treatment, a foul bed-sore developed over the left hip.

The patient was sent to me for operation by Dr. M. A. Starr, with the diagnosis of tumor of the cord in the region of its fourth dorsal segment.

Operation Oct. 20, 1900. Chloroform. A 5-inch incision was made from the second to the sixth dorsal spine. The spines and laminæ of the second, third, fourth and fifth dorsal vertebræ were removed. A moderate layer of fat covered the dura. It was slightly purplish in color. It was opened for a distance of four inches. The pia seemed congested and bulged outward



Case 8. Tumor compressing spinal cord Actual size

develop evening temperature, and for weeks until her death her temperature ran a septic course due to absorption from the bed-sores. The pain in the neck and chest was so severe that anodynes were necessary. Her stomach became very irritable and it was with difficulty that she could be fed. Towards the beginning of December she began to have periods of delirium and semi-consciousness and she gradually failed and died on Dec. 3, 1900.

The wound remained clean throughout the course of her illness, but there was an entire absence of any sign at repair, its edges being kept together by silk sutures and adhesive plaster. On microscopic examination, the tumor proved to be fibroma, though it contained some cells suspicious of sarcoma.

It is, of course, of the utmost importance that the lesion be located before operation. One can not ruthlessly sacrifice spinous processes and laminæ, and a large flap is not practicable as it is in operations on the brain. The location within certain definite bounds can almost invariably be settled. It is impossible, on account of the anatomic arrangements, to assign a certain lesion to any one segment of the cord, but it is almost always possible to locate a lesion to an area embraced by three spinal segments. The reason for this is evident. There is no spot on the surface of the body and practically no muscle (with the possible exception of some of the deep small muscles of the back) which is innervated

tissue it is sometimes difficult to distinguish between them. Likewise, in the dorsal and lumbar regions similar difficulties at times present themselves. Of course, in the former the ribs can generally be taken as a guide for locating the different spines, but, again, in stout people with strongly developed muscles this is not always easy.

Before considering the technique of the operation it may be well to make a few general suggestions in regard to spinal surgery.

1. The incision should be made as high up as possible. The main reason for this is that the nutrition of the

all progress ceased; the patient began to grow weaker; she began to suffer pain; the paralysis increased and in March a tumor developed in the epigastric region. She gradually grew weaker and died on April 10, 1901.

[2] One, Case 1, reported as lipoma, should probably not be considered in this connection.

The patient was treated for weeks and months with mercury and iodid of potash. Her symptoms during the summer varied somewhat, being for weeks at a time of milder type, but in the autumn they became rapidly worse. In the meantime, due to the delay necessitated by the employment of antisyphilitic treatment, a foul bed-sore developed over the left hip.

The patient was sent to me for operation by Dr. M. A. Starr, with the diagnosis of tumor of the cord in the region of its fourth dorsal segment.

Operation Oct. 20, 1900. Chloroform. A 5-inch incision was made from the second to the sixth dorsal spine. The spines and laminæ of the second, third, fourth and fifth dorsal vertebræ were removed. A moderate layer of fat covered the dura. It was slightly purplish in color. It was opened for a distance of four inches. The pia seemed congested and bulged outward, caused by the excess of cerebrospinal fluid. It was punctured and an ounce or more of fluid escaped. The cord looked somewhat atrophied, but otherwise normal. The third and fourth posterior roots were picked up with a blunt hook and divided. A director, passed both inside and outside the dura upward and downward for two inches, met with no obstruction. The dura was sutured with catgut; the muscles and skin with catgut and silk.

Very little reaction followed the operation. For forty-eight hours there was some increase in the muscular spasms and some decrease in the pain across the chest. It was evident, however, that the lesion had not been found and judging from past experience we concluded that the tumor was situated at a higher point; and accordingly on October 23 the second operation was performed. An incision was made from the first dorsal or upper termination of the former wound to the fifth cervical spine. In the original wound there had been no attempt made at repair. It was perfectly clean, but there was no agglutination whatever of the skin or muscular edges. The spines and laminæ of the first dorsal, seventh and sixth cervical vertebræ were removed. Towards the upper end of the incision the dura for a space of two inches looked rougher and redder than normal and to it the ligaments had been slightly adherent. Superior to this point there was marked pulsation of the dura. It was opened through the whole length of the incision three to four inches, and at a point opposite the lower three-fourths of the seventh cervical vertebræ, the interspace below and the upper part of the first dorsal was seen a mass somewhat sausage-shaped, resting under the pia about an inch and a quarter in length, two-thirds of an inch in breadth, and half an inch in depth. Its color was pearly gray, slightly pinkish. The cord under it was practically concealed by the tumor, to which it was connected by a thin layer of connective tissue. It was completely encapsulated and was easily lifted from the cord by division of a thin fascia and removed entire. (At the former operation the opening of the dura had extended to within three-quarters of an inch of the lower end of the tumor. The dura was sutured with catgut and the wound closed.)

See colored plate, marked Case 8.

The operation was followed by comparatively little shock. For some days she complained much of pain in the wound and excessive hyperesthesia across the upper part of the chest extending a little above the clavicles. The muscular spasms soon ceased and she complained of no contraction or pain, except in the upper part of the chest and back of her neck. The bed-sores on her hips slowly increased in size and their base consisted of a sluggish, foul, sloughing area.

In a few weeks she began to develop evening temperature, and for weeks until her death her temperature ran a septic course due to absorption from the bed-sores. The pain in the neck and chest was so severe that anodynes were necessary. Her stomach became very irritable and it was with difficulty that she could be fed. Towards the beginning of December she began to have periods of delirium and semi-consciousness and she gradually failed and died on Dec. 3, 1900.

The wound remained clean throughout the course of her illness, but there was an entire absence of any sign at repair, its edges being kept together by silk sutures and adhesive plaster. On microscopic examination, the tumor proved to be fibroma, though it contained some cells suspicious of sarcoma.

It is, of course, of the utmost importance that the lesion be located before operation. One can not ruthlessly sacrifice spinous processes and laminæ, and a large flap is not practicable as it is in operations on the brain. The location within certain definite bounds can almost invariably be settled. It is impossible, on account of the anatomic arrangements, to assign a certain lesion to any one segment of the cord, but it is almost always possible to locate a lesion to an area embraced by three spinal segments. The reason for this is evident. There is no spot on the surface of the body and practically no muscle (with the possible exception of some of the deep small muscles of the back) which is innervated by one nerve root alone. The anastomosis between the sensory nerves is so perfect that every spot of skin derives its sensation from at least three or more nerve roots or segments, and every muscle derives its motor power from at least two segments of the cord.

In addition to this it is known that the afferent and efferent tracts run up in the substance of the cord for a considerable and according to location a variable distance, that degeneration will at times follow up these tracts for a considerable distance, perhaps two segments, before it reaches the real nerve center in the gray matter of the cord. As a consequence the cause of a paralysis or irritation of a muscle or of an area of anesthesia may, instead of being at the segment into which the nerve root supplying said muscle or spot of skin enters, be located at a point a considerable distance higher up in the cord.

This is one of the reasons why in many of the operations for lesions in the cord the spot selected as its site has been found to be considerably lower than the spot where the lesion is found at operations to exist. On this account more than one operation has been fruitless. Case No. 10 is a good illustration of this. The symptoms were most misleading and reliance was placed on published rules and tables and the lesion not found at operation. Fortunately the result was not affected by this failure.

A difficulty which not infrequently presents itself in these operations is the determination of the exact position of the different spinous processes. This is especially true as regards the cervical region, and in short-necked, fat females it is often difficult, sometimes impossible, to accurately locate the different spines. Errors because of this uncertainty have more than once been made, and I know of no rule whereby in certain cases various spines can be definitely located. In the cervical region it is, of course, easy to say, find the seventh or vertebral prominence and count upward. This is certainly easier than to count downward, beginning with the axis or atlas. But it is not always easy to determine which is the seventh spine. The sixth cervical as well as the first dorsal spines are often almost as prominent, and in a neck covered by adipose tissue it is sometimes difficult to distinguish between them. Likewise, in the dorsal and lumbar regions similar difficulties at times present themselves. Of course, in the former the ribs can generally be taken as a guide for locating the different spines, but, again, in stout people with strongly developed muscles this is not always easy.

Before considering the technique of the operation it may be well to make a few general suggestions in regard to spinal surgery.

1. The incision should be made as high up as possible. The main reason for this is that the nutrition of the

soft parts below the seat of lesion may be impaired because of destruction of the nutritive cells in the cord. Another reason of less moment is that the lesion has generally been found above rather than below its point of location.

2. The operation should be done rapidly. But few vessels need the application of artery clamps and still fewer of ligatures. If a bold incision be made the bleeding will not be great and can be controlled by the use of gauze pads held down by broad retractors. At times it may be necessary to pack one side or end of the wound with sponges and while these remain for a minute or two the operator can work at some other part of the wound. In my recent operations I have employed but very few artery forceps and often not a single ligature.

3. Ample space should be afforded for proper examination of the cord. For this purpose the removal of at least three laminæ is generally necessary. Of course, in cases of fracture, bullet or stab wounds of the cord the removal of one or two laminæ may suffice; but at least in cases of tumor one should be careful not to be hampered by too small an opening.

4. Support after operation of the spinal column by means of braces or plaster-of-paris jackets has not seemed to me necessary; indeed, it seems to me it adds only to the discomfort of the patient. An experience of nearly twenty laminectomies has convinced me that it is generally useless.

There are two methods of operation for exposure of the spinal cord:

1. By means of a vertical incision through the skin down to the tips of the spinous process and then division and separation of the muscles attached to these until the posterior arch of the vertebral column is well exposed. The spines and laminæ are then removed by bone forceps and no effort made to save the fragments for replacement at the close of the operation.

2. By means of an osteoplastic flap consisting of skin, muscle, and the posterior arches of the vertebra, the flap if single remaining attached by a hinge situated at one or the other side or end, or if double the hinge being in the middle. The advantages of the first method are greater rapidity, less hemorrhage, and better access to the cord. Its disadvantage is that because of removal of bone there must be left a gap in the posterior arch of the spinal column. I do not place much value on this objection, as in the majority of cases no special weakness of the back results.

The advantage of the second method is that the bony flap is replaced and consequently the posterior bony arch is completely restored. Its disadvantages are that the operation takes more time, more blood is apt to be lost, access to the cord is less satisfactory and there is a liability that the nerve roots may be irritated by resulting callus or imperfect adaptation of the bony surfaces.

My own preference is for the first method. Subperiosteal removal of the posterior arches is theoretically desirable, but practically it is very unsatisfactory. It is, however, desirable to retain attached to the muscles as much periosteum, ligament, and tendon as is possible.

In regard to the instruments most suitable for laminectomy each surgeon will probably have his own preference; mine is for bone forceps, and I know of none better than the old-fashioned rongeur forceps of Luër. The handles, however, should be made a *little* longer. Many other ingenious and equally useful forceps have been devised for this purpose. Saws, both hand and electrical, are employed by some operators and it is claimed that the removal of bone can thus be accomplished more rapidly. I have not found this to be the case with hand saws, and the use of electrical saws for this purpose has always seemed to me dangerous.

In my own operations a median incision five to seven inches long is made directly down on the tips of the spinous processes; the muscles and tendons on each side of these are divided by knife or scissors until the laminæ are exposed. From these the muscles are rapidly stripped, the bleeding being mainly controlled and the sides of the wound retracted by broad retractors, under which are held pads of gauze or sponges. The spinous processes are then divided at their base by heavy bone forceps. The laminæ well out toward the pedicles are then gnawed off by means of Luër ronguer forceps. Sufficient bone is removed to give a good exposure of the cord covered by its dura.

If the lesion for which the operation be done is not then seen the dura is opened and the cord with its nerve roots thoroughly explored. With proper precautions the increase of risk due to the opening of the dura should be only slight. If a tumor be found, its removal will depend on its character and situation. If benign, it will be easily enucleated without hemorrhage. If malignant, hemorrhage may be severe if the growth has infiltrated into adjacent structures.

CONCLUSIONS.

1. The risk of the operation of laminectomy is slight.

2. Early operation is of the greatest importance. Operate before the onset of degenerate changes.

3. In tumor cases do not waste time with anti-syphilitic treatment.

4. Operate rapidly. Employ but few artery forceps or ligatures.

5. Support of the spinal column after operation is generally unnecessary.

LAMINECTOMIES FOR FRACTURES AND DISLOCATIONS.

No.	Name and Age.	Date.	Time after Injury.	Lesion.	Results.
1	E. G., 33	June 4, 1890	8 months.	Pachymeningitis, old fracture, 4th cervical vert.	Recovery.
2	G. A., 65	July 13, '90	12 hours.	Fracture, 3d cervical.	Death in 12 hours.
3	J. H., 42	June 27, '91	7 days.	Fracture, 10th dorsal.	Death in 66 days; sepsis due to bedsores and cystitis
4	J. T., 27	July 3, 1891	9 hours.	Fracture, 6th dorsal.	Recovery.
5	T. C., 41	June 1, 1892	6 hours.	Fracture, 7th cervical.	Death in 10 hours.
6	M. M., 35	Oct. 5, 1901	8 days.	Dislocation between 4th and 5th cervical.	Death in 12 days.

LAMINECTOMIES FOR TUMORS OF THE CORD.

No.	Name and Age.	Date.	Duration, months.	Location.	Lesion.	Results
1	E. R., 50	March 29, 1894	5	7th and 8th dorsal.	* See note.	Death in 15 months from tuberculosis.
2	M. H., 42	March 6, 1894	11	5th dorsal.	Sarcoma..	Death in 18 days due to sarcoma lung, pleurisy.
3	E. K., 39	May 22, 1900	28	2d lumbar.	Sarcoma...	At end of 13 months patient well.
4	Mrs. W. 37	Oct. 20, 1900	10	7th cervical.	Fibroma.	Death in 43 days; sepsis due to bedsores.
5	H. M., 30	Nov. 13, 1900	2	2d, 3d, & 4th lumbar.	Sarcoma...	Death in 5 months; exhaustion.
6	P. D., 46	May 28, 1901	5	2d lumbar.	Sarcoma...	Recovery.

* Reported in Am. Journ. Med. Sc., June, 1895, incorrectly as lipoma of 10th dorsal. Future history of case showed it to be tubercular disease of the 7th and 8th dorsal.

SPINA BIFIDA OR HYDRORRHACHITIS.*

PAUL F. EVE, M.D.
NASHVILLE, TENN.

Spina bifida or hydrorrhachitis is a congenital malformation consisting of a cleft in the vertebral column with protrusion of the lining membranes of the spinal cord.

This deformity is caused by an arrest of ossification of the vertebral arches, and is situated in any region of the vertebral column. It is more frequently found in the lumbar region, which constitutes about 50 per cent. of all cases; there are probably about 12 per cent. in the lumbo-sacral region, and about 25 per cent. in the sacral region. It is frequently associated with other congenital deformities, such as hydrocephalus, talipes, harelip, etc.

It consists of a tumor, varying in size from a marble to an adult's head, and occupies the central portion of the canal over the posterior aspect of the vertebral column, and is intimately connected with the canal in which a gap is felt in the bones of the vertebra upon raising the tumor. The tumor is elastic, smooth and fluctuating, and in some instances wholly translucent; in other cases it is covered by integument, which may be normal in character, but more often the skin is thin, covering the base and sides of the tumor, or finally emerging into the transparent membranes, which forms the apex of the growth. In some cases the tumor is peduncular, in others sessile.

In this malformation there may be entire division of the vertebræ, involving even the bodies, with partial or complete absence of the lateral arches; or there may be perfect development of the lateral arches with the want of union at the median line. This protrusion generally takes place during the latter months of the fetal life; it may, however, be unobserved until some weeks or months after birth.

At present there are recognized three distinct varieties of this affection: 1, meningocele, the protrusion consisting only of fluid held in the membranes of the spinal cord; 2, meningo-myelocele, where we have the addition of a portion of the cord in the sac; and 3, syringo-myelocele, the central canal of the spinal cord being dilated, thus forming the cavity of the sac.

This is, as we are all aware, a very fatal affection, few children surviving longer than five or six months after birth, many dying before that time. Death usually occurs from convulsions, or ulceration and rupture of the sac. If the sac is ruptured during parturition, the infant is nearly always stillborn; and if it becomes open after birth, death usually follows in a few hours, the immediate cause of death being convulsions from the pressure being taken off the brain in consequence of the loss of the cerebrospinal fluid.

In the diagnosis of this affection there are some very important facts which should be borne in mind. The tumor is congenital and occupies the central portion of the posterior aspect of the spine. By pressure it is diminished in size, tension being easily seen at the fontanelle. By raising the tumor we are often enabled to discover the loss of the spinal arches and map out the bony margins of the spinal bodies; and when the child cries or coughs the tumor becomes more tense.

On account of the very fatal termination in the majority of these cases it can be readily recognized that the surgeon is warranted in pursuing any treatment which promises a prolongation of life or a radical cure. This treatment we can readily divide into palliative and radical. In the palliative treatment, when the tumor is small, or of moderate size, considerable pressure should be exerted upon it, either by the application of collodion, or a cup-shaped truss either made of surgeon's wool or some soft material, this pressure being maintained by a common roller bandage or adhesive strips. This treatment is suggested by a few accidental cures which have resulted by pressure being exerted by binders, which have been inadvertently placed tightly around the child's body, and in this way compressing the tumor. Some surgeons supplement this treatment by acupuncture, their method being by repeatedly pricking the thin portion of the cyst wall with a fine needle, allowing the fluid to ooze away upon an aseptic dressing; another method, following a similar course, is by tapping the cyst with a fine trocar and cannula, one or two drams of the fluid being drawn off at each tapping, gentle pressure being maintained either by pads of wool or cotton or the application of collodion.

In 1848, Dr. Brainard reported a number of successful cures by the injection of iodin into the cyst. The rules laid down by him are: 1, to make a puncture subcutaneously in the sound skin by the side of the tumor; 2, to draw off no more fluid than the quantity of fluid to be injected; 3, to evacuate the contents of the sac and, if symptoms of irritation supervene, to replace this fluid immediately with distilled water. The solution he generally used was iodin and iodid of potassium in the proportion of one-quarter grain of the former and three times the quantity of the latter to one ounce of distilled water. Morton's fluid has been lately employed more or less with success, and consists of 10 gr. of iodin, 30 gr. iodid of potassium to 1 oz. of glycerin. Two drams of the fluid are generally drawn from the cyst walls and replaced by the same quantity of this injection. These injections are repeated at intervals of from one to three weeks, so long as inflammation continues.

The radical operation consists in the excision of the sac. Dr. Bayer has reviewed the whole subject of spina bifida, and has discarded the treatment by acupuncture, seton, or trocar, and he condemns the injection of iodin or other irritants into the sac, and considers this condition to be one analogous to hernia, and suggests that the treatment of this affection should be maintained upon the same lines. He points out the danger of meningitis following this plan of treatment is no greater than that of peritonitis following the treatment of hernia, and as compared with the operation for hernia is both safer and more certain of success.

It does seem to me, from the statistics gathered from the treatment by tapping followed by the injection plan, the results of which have been most unfortunate, we are warranted, especially in this aseptic age of surgery, to treat this affection after the suggestion of Bayer; especially when the tumor is small and peduncular. Some very brilliant results have followed this plan of treatment. The outlines of the operation are as follows: An incision is made through the skin on each side of the tumor about an inch from its base and two flaps are carefully dissected off the tumor, the sac is then punctured, withdrawing the fluid, and the sac so cut and separated as to leave two flaps, one longer than the other. Should the nerves or portions of the cord be found adherent to the sac, they are carefully separated from the wall of the cyst and returned to the spinal canal. These flaps are now sutured, the approximation being so close that leakage will be impossible; the skin flaps are now brought together by silk or silkworm gut sutures, and should there be a deficiency of skin for covering, sufficient amount can be obtained by dissecting the skin from the loin and transplanting it.

---

* Read at the Fifty-second Annual Meeting of the American Medical Association, in the Section on Surgery and Anatomy, and approved for publication by the Executive Committee of the Section: Drs. W. J. Mayo, H. O. Walker and A. J. Ochsner.

In looking over the literature on the subject of operation by extirpation, I found among some of the rules laid down the following: Extirpation is unjustifiable in very young infants; in cases complicated by extreme hydrocephalus, paraplegia, or serious nerve lesion; and again, where also the disease is very extensive and the want of a normal amount of integument is inadequate for covering the outside of the cleft. The indications advised for such an operation are as follows: Where the child is over 7 or 8 years old, and where the tumor is rapid in its growth, rupture threatened, and where normal skin is abundant for covering.

In consulting the authors on this subject, I am also impressed with the fact that the great majority of them are united in condemning the ligation of the sac. I therefore desire in this connection to report the following very interesting case:

On March 5 I received a communication from a local physician, stating that he had under his observation a baby of tender days, who had a fatty tumor upon the back, and which had a nevus developed upon its most salient point. The tumor, he also stated, had been growing quite rapidly in the past three weeks, and he was exceedingly anxious to know what course to pursue. I advised him to bring the child to Nashville for an examination, which he accordingly did on the evening of March 18. On the next morning, in conjunction with Dr. W. A. Bryan, I called upon the family and made a very careful examination of the baby. I found a tumor between the scapulæ, situated in the median line of the spine, about the size of an orange, translucent for about three-fourths of its diameter, globular in shape and pedunculated.

The base of the tumor was covered by normal integument. My examination also disclosed a cleft in the spine corresponding to the fifth dorsal vertebra, and I was enabled to discern the absence of the lamina and the connection of the tumor with the central spinal canal. The head of the child was drawn backward, and was apparently too large for the size of his body; there was, however, no bulging of the fontanelles, their closure being about normal for this period of life.

The following history was obtained from the mother: The family history on both sides was excellent, with not a single trace of deformity in any other member of the family, both lines having arrived at an advanced age of life. The child was born on Dec. 27, 1900, and weighed 5 pounds at his birth. Shortly after birth the mother noticed a tumor about the size of a partridge egg, with a nevus over the most salient point, and which, she informed me, grew rapidly from the date of the child's birth, increasing when the child cried, and producing a slight bulging of the fontanelle, which was also noticed when I made gentle pressure upon the base of the tumor.

I gave it, as my opinion, that we had a spina bifida to deal with, which was concurred in by my consultants, and that on account of the rapid growth of the tumor, and the attenuated condition of the sac, together with the small size of its pedicle—which in diameter was only about 1 to 2 inches—that the best procedure would be total extirpation and advised an operation. The consent of the parents and consultants being obtained, the patient was prepared for an operation, which was performed on April 20.

I was assisted in the operation by Dr. W. A. Bryan. Chloroform was the anesthetic chosen, but as the patient did not do well under this anesthetic, it was changed to ether, which proved very satisfactory, the patient standing it excellently during the whole of the operative procedure. An irregular incision was made at the base of the tumor, the object being to obtain as large a skin flap as possible. The skin was dissected from the sac, which required a very delicate dissection for separation, and the pedicle disclosed, which upon examination proved to be about the size of a quarter dollar. The pedicle was seized between two fingers for the purpose of seeing if there were any spinal nerves in the contents of the tumor, but none being discovered by this examination, a clamp was carefully adjusted to the pedicle and symptoms watched. Nothing of an alarming character developing, the sac was opened at its side and drained. This incision was now enlarged and a very careful examination made of the contents of the interior of the sac, which proved to contain nothing but cerebrospinal fluid. The pedicle was now transfixed beneath the clamp by a needle loaded by a double silk ligature; this was interlocked and the pedicle ligated. The stump of the pedicle was stitched by a double row of catgut sutures and made perfectly water-tight; the skin flap—which proved abundant—approximated by silk sutures and the wound dressed.

From March 20 to March 25 the temperature was below 100 F., with corresponding pulse rate and respiration; the first dressing was made at this date and no leakage discerned. On the evening of March 25 the temperature rose to 103 degrees, which proved to be due to a stitch-wound abscess in the skin flap; this stitch was removed and the wound thoroughly cleansed and dressed.

The temperature from this date immediately decreased, the wound being dressed each day, and on March 27 it struck the normal line. The remaining silk sutures were removed on the seventh day, the wound found almost healed, and from this date the child made an uneventful recovery, and was dismissed entirely well on April 8.

In conclusion, I desire to call attention to the following points:

The child I operated on was less than three months old; the tumor was rapid in its development, and threatened rupture was imminent; the pedicle was small, and consequently easily dealt with.

With authors to the contrary, I claim the only conservative plan that could be adopted is the one carried out in this instance; which leads me to say that, in the vast majority of cases, each individual surgical case is a law unto itself, and we have to exercise that good common sense, without which surgery would be at a standstill.

Cacodylate of Soda.—A correspondent calls attention to the editorial in The Journal for August 17, p. 455, on "Cacodylic Acid." He says: "There is an error in calling this cacodylic acid, for cacodylic acid as such is not used medicinally to any extent, but the sodium salt, known as 'cacodylate of soda,' is extensively used in some parts of the country, and I have had a broad experience in observing its effects. The cacodylic acid has been known for many years as possessing the virtues of arsenic, but it could never be used satisfactorily until it was combined with a sodium base. It is now used both hypodermically and internally, and I consider it one of the best remedies we have for many conditions."

THE IMMEDIATE AND REMOTE EFFECTS OF BRAIN INJURY.[*]

D. S. FAIRCHILD, M.D.
Professor Surgical Pathology, Medical Department, Drake University; Surgeon, St. Joseph Hospital.
CLINTON, IOWA.

Immediate Effects.—The phenomena which immediately follow as the result of brain trauma are interesting chiefly on account of their diagnostic value in revealing the nature and extent of the injury and are of some importance in determining the questions of prognosis and treatment. It must be considered, however, that in many cases the early manifestations may not reveal the seriousness of the lesion fully and may be misleading. On the other hand, the first symptoms may indicate a more grave condition than the subsequent history will confirm.

The early symptom most generally observed in serious head injuries is a state of unconsciousness. What this may signify can not always easily be determined from the symptom alone. The question of importance in this connection to be considered at an early moment is, whether the unconsciousness is from hemorrhage, or from concussion or contusion of the brain. The manner in which the injury is received is of the utmost importance in determining this question.

1. Whether the patient has fallen from a height, striking on his head in such a manner as to produce a serious lesion at the base of the brain.

2. If a direct blow has been received on the convex surface of the skull and of such a character as to produce a lesion in the cortical or subcortical brain substance. Having determined with reasonable certainty that the lesion is in the convexity of the brain, the value of ascertaining whether or not a considerable hemorrhage has occurred is very great in determining the immediate result of the injury and the treatment to be employed. The nature of the blow and its location may be of some importance, but can not always be relied upon. For instance, it is known that a man has received a blow on his head, but when he comes under professional observation, the marks of it may have been so completely obliterated, or may not have existed at all, or may be so general in character as not to reveal where the force of the blow was applied, and unless there are some focal symptoms the surgeon may be in serious doubt as to what has really transpired within the cranial cavity, and he patiently but inconsiderately waits for consciousness to return while an increasing hemorrhage is going on.

The unconscious state in itself will not reveal whether it is due to concussion or hemorrhage—except the hemorrhage from a cerebral artery, as in an apoplexy—and as the hemorrhage due to trauma is generally meningeal it does not produce the coma of a cerebral hemorrhage. While the general manifestations of unconsciousness do not indicate the cause, the manner of approach is in many cases significant. The appearance of the unconscious state some minutes or an hour or two after the accident or the return of consciousness after a primary loss, followed shortly by a reappearance of the former state, are almost diagnostic.

The unconsciousness due to hemorrhage is of course a pressure unconsciousness, and if the pressure is from a fracture with depression, the physical condition will reveal the fact, or if the marks of violence are found over the region of the middle meningeal artery, the fact should be very helpful in our diagnosis. If then the first symptoms of intracranial injury are determined to be from a rupture of a meningeal artery, particularly the middle meningeal, the immediate effects of the injury may be regarded as serious unless a prompt surgical procedure is employed. Three cases are now presented illustrating the foregoing observations:

FIRST SERIES.

Case 1.—A brakeman was found lying on top of a freight car in an unconscious state. The cause of injury and the immediate symptoms were unknown. No marks were found on his person. He came under my care three days after the injury. He was unconscious, but somewhat restless when disturbed. There were no focal symptoms, but the long-continued unconsciousness was significant of some serious brain injury, which it seemed proper to especially inquire into. When the scalp was shaved there appeared to be a slight tumefaction in the anterior temporal region. The skull was exposed, a linear fracture was found crossing from frontal bone into parietal without displacement. Trephined over middle meningeal artery. A large clot of blood was found from rupture of artery. Clot removed, patient recovered and finally resumed work.

Case 2.—A fireman struck his head against the side pieces of a bridge; train not moving rapidly. He was picked up in an unconscious state. I saw him three or four days after the accident. He was still unconscious. Paralysis of right arm, right leg and right side of face. Diagnosis: Compression from sub-dural hemorrhage, left side. Attending physician and friends opposed to operation at this time and trephining was not resorted to, contrary to my judgment. A week later he began to manifest evidences of returning consciousness. It was then discovered that he was completely aphasic! Could produce unintelligible sounds, but could not utter a word. In about three weeks was able to say, "yes," and "no." Could move his paralyzed leg a little, improvement appearing in face, speech and lower extremities in about equal degree, reaching arm and hand last, i. e., the pressure was greatest and most persistent in motor centers for arm and spreading out above to centers for lower extremities and below to face and speech centers. Cleared up in upper and lower extremities of motor area first and approached middle points last. The man made a complete recovery and resumed his employment as a fireman. I have always doubted the wisdom of the let-alone treatment as a principle in brain surgery, notwithstanding the fact that this patient recovered without operation.

Case 3.—A young man, 24 years old, received a blow in the right temporal region from the fist of a companion during a controversy. The man was not knocked down, and it was supposed that he was not seriously injured. Walked to a house near by. Soon after complained of a headache and dizziness. Laid down on a couch. Two hours later he was found unconscious. After an interval of two hours more, he was seen by a physician, who apparently did not regard the case as serious. During the night the man died. Was present at autopsy ordered by coroner. No fracture of skull. Rupture of middle meningeal artery with a large hemorrhage which produced the fatal result.

The three cases above referred to illustrated three important classes of facts in relation to head injuries: 1, an indeterminate degree of trauma without definite symptoms to indicate the extent of injury; 2, an indeterminate degree of trauma with definite symptoms of a focal character; 3, a definite degree of trauma with definite symptoms to indicate the nature of the lesion. All were cases of hemorrhage and amenable to surgical treatment. All were due to direct violence applied to the head without the complicating influence of falls in which the weight of the body adds an important factor in damaging the brain at points remote from the application of force as seen in another series.

---

[*] Read at the Fifty-second Annual Meeting of the American Medical Association, in the Section on Surgery and Anatomy, and approved for publication by the Executive Committee of the Section: W. J. Mayo, H. O. Walker, and A. J. Ochsner.

SECOND SERIES.

Case 1.—A young lady was riding in a platform spring wagon. In crossing a bridge, the bridge fell a distance of 20 feet, striking on the surface of the water. She was not thrown from her seat and was apparently not much injured. She disengaged herself and walked a distance of nearly a half mile for help. Returned home and was apparently well for three days and then began to manifest speech difficulties. The aphasia increased and finally became complete. There was twitching of the muscles, particularly of right side. Became dull and stupid. Had a rise of temperature and finally fell into an unconscious state. She developed secondary pneumonia and died thirty days after the accident. I saw her a few days before she died and afterwards assisted in the autopsy. It was shown that at the time of the injury the left second frontal convolution and striate body were lacerated, establishing a communication between the left lateral ventricle and sub-arachnoid space. From this focus a process of softening had extended into the left third frontal and farther into the striate body. The vessels in this region were much congested and there was a considerable increase of cerebrospinal fluid tinged with blood. There were no clots and the blood seemed to come from numerous ruptured capillary vessels.

Case 2.—A man was sawing off a large limb from a tree twenty or thirty feet from the ground, and was sitting on a limb below. When the sawing was nearly complete the limb fell, striking him in the head and carrying him to the ground. He was found unconscious, with an ugly and extensive scalp wound in right parietal region. No fracture of skull. The location of the wound and the symptoms taken together apparently excluded hemorrhage. On the third day skull trephined at seat of injury. Dura tense and pulseless; incision was followed by the escape of considerable clear serous fluid. Drainage provided for. Fluid continued to escape freely for several days, when the patient died. No autopsy. It was presumed that the combined effects of the blow and the fall produced such widespread damage to the brain as to result in death. The skull was very thick, and no doubt offered great resistance to fracture influences.

Case 3.—A brakeman was thrown from a freight train in a collision. Train moving rapidly. He was found unconscious, with many bruises on his head. Saw him on second day. No fracture of skull discovered. No focal symptoms, but unconscious. Trephined at the point of apparent greatest injury—in right temporal region. Dura protruded into opening, pulseless; incised dura. a considerable quantity of clear fluid escaped with some force. Brain considerably depressed at this point by the accumulated fluid, but came up after being relieved of pressure. The man died a week later from an injury to the lung by a fractured rib. He is said to have shown signs of returning consciousness.

The above cases are selected to show the influence of much more violent injuries to the brain from the existence of more widespread influences in the organ itself. In the first series the force of the injury was expended upon a distinct and circumscribed area of skull surface and produced lesions in the brain of limited extent—chiefly pressure influences arising from hemorrhage. These cases, from the nature of the injury and the location, together with the symptoms following, point so clearly to what has transpired in the skull that a careful consideration of all the facts ought to lead to an early diagnosis and an operation for the relief of conditions, which are easily within the reach of the surgeon and which promise the most brilliant results.

The second series of illustrative cases present certain important pathologic facts. The direct injury to the brain may not have been more serious in its effects than in the first series, but the indirect influence of the fall, the jar to the skull contents and the movements of the cerebrospinal fluid may have effected more or less widespread contusion or laceration of the brain.

The first symptom—unconsciousness—may present identically the same phases and leave nothing in this respect to differentiate the two classes of cases; but when the surgeon carefully considers the history of his case in so far as to estimate the nature of the force and the manner of its application, he will be able to more than make a guess as to the gravity of the case, its prognosis and the principle of treatment to be employed.

A third series of cases illustrates the effect of a more limited area application of force than the first. The damage to the brain will chiefly depend upon the part of the brain involved, the extent of brain penetrated, the question of infection and the treatment employed. A variety of the class of cases here considered is well known to the military surgeon who has had actual experience in an active campaign. For obvious reasons I shall omit any particular reference to gunshot wounds of the brain and consider only such injuries as occur in civil practice. These cases are not generally dangerous to life if proper consideration is given them early; on the other hand, neglectful care at an early moment is liable to be followed by brain infection, particularly so if the surgeon fails to sufficiently explore the wound to remove fragments of skull and other foreign bodies which may be driven into the brain.

THIRD SERIES.

Case 1.—A farmer was stacking hay, using a hay fork moved by horse power. The frame-work over his head fell in such a manner that the end of a projecting bolt struck him in posterior frontal region. The skull was penetrated. As soon as possible I examined the man and found a punched-out hole about ¾ inch in diameter. This was enlarged sufficiently to permit of an exploration. Some fragments of bone and a piece of felt hat were removed from the brain. The patient recovered without sequelæ.

Case 2.—A boy, in an attempt to jump on a moving freight train, fell and lost his right arm at the shoulder joint, under the car wheels. At the same moment the end of an exposed bolt struck him on right frontal bone just above the hair line. When placed on the operating table he had a series of convolutions, which subsided when anesthetized. The bolt had penetrated the skull, carrying into the brain some fragments of bone. The opening in skull enlarged and fragments of bone removed. Recovered without any mental impairment.

Case 3.—A young man was struck in frontal bone just below hairy scalp by a pistol ball. The ball split on the outer table of skull. It was found that fragments of bone had been driven into the brain causing some laceration of brain tissue. The fragments were removed after enlarging the opening sufficient to explore with finger. Patient recovered without mental or other nerve impairment.

The treatment of these cases involved no difficulty whatever, but if it had not been employed promptly with a view to meeting certain cardinal principles of surgery, infection would certainly have occurred early with the most disastrous results. The cases of the character above described were not followed by any remote effects. It will be observed that the anterior lobes of the brain were injured in all these patients. A similar series could be presented where the injury was to the posterior region of the brain with less fortunate termination, both as to immediate and remote results, particularly the latter. It has been observed by a number of writers that injuries to the posterior regions of the brain have been more serious than similar injuries to anterior portions.

Remote Effects.—The second section of this paper relates to the remote effects of brain injury. The cases referred to, as a rule, present no alarming symptoms immediately after the injury, and many of them present no indications for operative procedures. Others apparently do not make exception to the surgeon who has had considerable experience in brain injuries. They include cases which the practitioner believes will recover if left to themselves, and yet the experienced surgeon can see indications which point to serious results in the future, although as to the present recovery may be confidently expected.

I find it convenient to group the cases into two classes: 1, those involving pressure lesions, manifesting focal symptoms or irritation lesions, expressing themselves in Jacksonian epilepsy; 2, those involving nutrition lesions resulting in more or less extensive sclerosis manifested by mental symptoms of a more or less marked degree.

The importance of considering with care all cases of injury to the head which may produce lesions in any degree amenable to surgical treatment is very great. Experience has abundantly shown that if a course of waiting is permitted for future results, when the sequelæ are actually developed, an operation is then too late to cure what might have been prevented.

In the first class above referred to of cases considered in relation to remote effects of head injuries, may be included cases of fracture with depression and without symptoms, and cases suspicious of depression, or hemorrhage with focal symptoms. Fracture with depression and without symptoms will from the nature of things exercise a localized pressure upon the brain surface and particularly if a rough edge or spicula of bone bears upon the dura, and lead in many cases to irritation and local nutritive changes in dura, and pia-arachnoid with adhesions to cortex and even connective tissue formations in the cortex itself. In other cases where the examination shows no apparent fracture or depression, focal symptoms appear proving conclusively that a pressure lesion exists in the cortex, which in time results in organic changes in the brain giving rise to unfortunate sequelæ, and when the results do appear the effect of a late operation is always problematic. From my own experience I can not see what excuse can be offered for a neglect to restore, as far as may be, normal conditions by an operation. It is no doubt true that in some instances no serious results follow from the class of injuries above referred to, but the experience of surgeons point to so many individuals whose usefulness has been seriously impaired by secondary brain changes that the most thoughtful consideration should be given them and operative procedures should not be withheld when a doubt exists.

A child 2 years of age, while sitting in a high chair, was in some accidental way thrown backwards, striking the back of its head on the floor. The occipital bone was somewhat depressed. Some time later it was noticed that the child could not see well, and when it came under my notice two or three years later was totally blind. There was plainly pressure on the occipital lobe with certain secondary changes, leading to total blindness.

A young man was standing on the railroad tracks at a street crossing, watching an approaching train. An engine came along on the track on which he was standing and knocked him off. He was unconscious for two or three days. His physician found a scalp wound crossing from left to right parietal bone in posterior region, but no fracture. It was noticed during the period of unconsciousness that the right leg did not move freely, but the doctor saw no significance in this fact. Two months later I saw the man as the medical officer of the railway company, and found a scar two inches in length extending from left to right side of median line in posterior parietal region. The principal force of the blow was on left side over superior parietal gyrus or over leg center. Result was incomplete motor paralysis of right leg. No doubt a pressure lesion from a depressed fragment of bone existed. He refused treatment on account of a prospective claim for damages. Doubtless the unfortunate remote result could have been avoided by proper early surgical treatment.

In a small percentage the traumatic aseptic focus in the brain becomes the point of departure of lesions leading to a slow process of interstitial sclerosis more or less extended. These local disturbances of nutrition are closely connected in many of these cases with a permanent pressure irritation arising from untreated lesions which are within the reach of the surgeon and follow unwise conservatism.

In my own experience no case has occurred in which a localized lesion in the brain has been followed by either epilepsy or insanity when early operative treatment has been employed, except in wounds of the brain which have healed with scar production; while on the contrary, I have opened the skull many times at the point of an old injury for epilepsy or mental derangement with uncertain benefit and found localized organic lesions in the brain which I am quite sure in most cases could have been avoided.

The second class of head injuries are not uncommon and are particularly serious in regard to future results because of the fact that they involve widespread minute lesions which remotely affect the nutrition of the brain and bring about changes in the delicate mechanisms of the organ. The more diffuse sclerosis of a more widely extended nutritive disturbance is quite beyond the reach of the surgeon and the sequelæ must be regarded as permanent.

I have among my list a number of cases, particularly among trainmen who have fallen from rapidly moving trains and received head injuries, the symptoms of which precluded the probability of a fracture of the skull or of any localized hemorrhage, but were unconscious for several days. The return to consciousness was preceded for several days or weeks by a mild delirium, but they finally regained their mental balance. returned to work, and continued their employment for a few months or a year when it became necessary to discharge them from service on account of a developing insanity. The pathologic condition, as it appeared to me, was a more or less widely diffused connective tissue proliferation or a chronic meningitis.

Among localized brain injuries which should be excepted when considering trauma, may be mentioned scar proliferation from wounds of the brain itself. The scar thus produced may remain as a permanent condition or may undergo cystoid or other degeneration developing late symptoms. In a limited number, these cases are amenable to surgical treatment if considered early.

An interesting case of this kind came under my observation a few years ago. A boy 9 years of age received a gunshot wound. The ball entered the orbital plate near the inner angle of right eye and escaped from right parietal bone posterior to the upper end of the fissure of Rolando, passing through the fibers of the internal capsule. I saw him six years after the accident, on account of the appearance of the premonitory symptoms of epilepsy. The boy had suffered no mental impairment, but the opposite arm and leg had not grown equal in length or size with those of the right side and he could use them but imperfectly. The scar tissue at point of exist of ball was dissected out. The opening in skull was enlarged and brain exposed. A well-developed cystoid scar was found and dissected out with complete relief to the epileptic symptoms.

Simple and compound fractures of the skull are omitted, except in so far as they relate to hemorrhage or future conditions of the brain. It is only intended to consider varieties of injuries which present elements of doubt as to what has occurred within the cranial cavity concerning immediate results which may interest the surgeon and the question of remote effects which may or may not be in a measure under the control of surgical treatment.

A large percentage of the cases referred to in this paper have possessed elements of liability either on the part of corporations or individuals and have potentially or in fact been the subjects of medico-legal investigation. For this reason not only have they been considered from the standpoint of the operating surgeon, but also for the purposes of an expert opinion. The observations referred to are now of great service to me in determining at an early moment the probable pathology of brain injuries with the view of obtaining the best practicable immediate results with as clear a conception as possible of what the future may bring. The following conclusions are offered:

1. Violence of no great intensity when applied to a limited area of skull may cause a fracture with only momentary displacement with a rupture of a meningeal artery, or a rupture of an artery without fracture.

2. A localizing injury which may lead to a fracture without displacement and hemorrhage does not as a rule cause a serious permanent brain lesion if early and judicious surgical treatment is employed.

3. A fracture may occur without apparent displacement, yet a real localized pressure on the brain exist which may cause irritative changes involving a more or less extended sclerosis and remote secondary results, as epilepsy or mental impairment.

4. A blow may be received on the head which may produce a more or less extensive laceration of the scalp which in itself is not serious. But the fall from a height or from a rapidly moving train may produce more or less extensive contusion or laceration of brain tissue leading to serious immediate or remote effects.

5. A fall from a height or moving train may without a fracture cause directly or indirectly a contusion or laceration of brain tissue or so disturb the cerebrospinal fluid as to primarily bring about such changes and cause immediate results or secondary serious remote effects by inducing degeneration and final interstitial changes producing insanity.

6. An injury may be of such a character as to produce a localized wound of the brain that may heal with the production of scar tissue which may extend, may or may not undergo cystoid or other degeneration with serious remote effects.

7. In the absence of localizing or other definite symptoms to indicate the nature of the lesion, the character of the accident and the manner in which the force is applied is of great value in reaching a conclusion as to the probable nature of injury to the brain.

DISCUSSION IN SYMPOSIUM ON SURGERY OF THE BRAIN AND SPINAL CORD.

Dr. W. W. Keen, Philadelphia—I think Dr. Eve has taken in his paper the proper ground in reference to the treatment of spina bifida. The time was when the injection of Morton's fluid, tapping, etc., were all we could do, but with the advent of modern cerebral and spinal surgery, and especially the introduction of the antiseptic and aseptic methods, I think we ought, except in occasional cases, to advocate such a treatment, and subject our cases of spina bifida to operative treatment, with or without closure of the opening in the spine, according to the nature of the case.

In Dr. Fenger's paper,[1] I was disappointed, in that he limited the exploration to the search for pus. We must have a very clear distinction in a methodical exploration of the brain for collections, either of pus or of purulent or semi-purulent fluid or of serum in some cases which may be outside the ventricle, but yet in the substance of the brain, or in other cases which are distinctly in the ventricles themselves. I have employed very much the same methods which he has advocated, by various instruments, especially for exploration outside of the ventricles, but, of course, in the texture of the brain itself. In the ventricles, however, we can also find fluid. More than ten years ago I proposed as a methodical operation and I formulated the process of several routes by which the ventricles themselves could be reached, and the ventricular or other fluid that may be there could be evacuated from the ventricles and the ventricles washed out—even irrigated from one side to the other. Unfortunately, a very elaborate paper which I presented at the International Medical Congress in Berlin was lost by the secretary and as I have no copy I have never had enough leisure to pursue the subject again; in that paper I have gathered all the recorded instances in which the ventricles have been opened by accident or design, and I will show very clearly that opening the ventricles is not the dangerous procedure or the dangerous accident that has been supposed. Within about six weeks I have had a very remarkable case and wholly an exceptional one in my experience, a young man who, in 1892, was thrown from a horse and had his skull fractured in the posterior lateral region on the right side. Epilepsy supervened seven years afterwards, in 1899, and I trephined him about six weeks ago, because at the time of his accident, there having only been small bits of bone removed, it was possible that there might be some lesion inside of the skull which had not been discovered. After I opened the skull I found the dura and opened it and evacuated a considerable quantity of fluid, and then at a distance of a centimeter (in size), not having seen any of the cortex of the brain, I found the skin over this membrane was scarcely as thick as the lining which covers the inside of an egg. It contained fluid, color dark. On incising this, a large amount of fluid escaped. Doubling up a bit of silkworm-gut to make a measure and yet not too sharp to puncture the brain tissue, I passed this in and found that I entered the cavity 10 centimeters in depth. Finding so large a cavity and desiring to know the nature of it, I incised a little farther this inner membrane. Then, to my astonishment, when I separated the edges and looked in by means of the electric light, I found that I opened widely the lateral ventricle. There was no free cerebral tissue arching over the lateral ventricle at all. Whether this had been absorbed as the result of accident or whether it had been destroyed as the result of accident, I can only surmise at the present time. I confess I was greatly startled when I saw this large open cavity with its choroidal plexus; I was perplexed to know what to do, but afterwards I concluded, in view of the fact that there would be some hemorrhage, that it would be proper to drain for a time. I inserted a small amount of gauze and brought this outside of the scalp wound which I then closed. To make a very brief story, next day I removed the drainage. Twice after that I was obliged to insert a pair of forceps, at once evacuating a considerable accumulation of fluid, which produced headache and which seemed to portend the possibility of epilepsy returning and the man recovered. Two weeks after the accident he had two or three epileptic attacks in the course of one day. Since then, as far as I know, he has had none. But, of course, the time passed is too short to decide whether any permanent good will be done or not. I fear not, but the proposition that presented itself to me was that open ventricle, opened practically its entire length. It was totally new and I was very happy indeed to feel that the solution apparently seemed to be the correct one.

---

[1] Dr. Fenger's Paper on "Methodical Exploration of the Brain for Fluid" has not yet been handed in for publication.

As to Dr. Fairchild's paper, I was very much interested in it and I think he has taken quite the right ground that interference is imperative upon us in these cases. In hemorrhage, of course, of a typical character, we have the three consecutive stages which are so important for us to recognize, namely, unconsciousness or partial unconsciousness of stunning from a blow; the recovery from this, and then, later, as either drop by drop, or in large quantity, the blood accumulates, the secondary unconsciousness which is due to pressure from the blood clot; but we must draw very sharply in our minds the distinction between the two totally different rates at which the blood accumulates. If you have a small rupture, a little laceration of a small branch of the middle meningeal or middle cerebral, you will have little leakage of blood, that will come drop by drop and you will have the period of secondary unconsciousness postponed. Or, if on the contrary, a large branch, and especially the main branch of the middle cerebral, ruptures, then you have the blood pouring out so rapidly that the period of unconsciousness between the two is obliterated. After the man recovers from the unconsciousness of stunning or blow, the unconsciousness is very apt to overlap. The other of the two experiences I had, was one of a man who fell to the floor of his barn from a hay-mow. I saw him three hours after the accident. There was no fracture of the skull. He had two or three wounds of the skull which I explored, but found no fracture. He was absolutely unconscious with stertorous breathing, with no paralysis; there was no motion; no method of determining voluntary or involuntary—I mean no paralysis of one side of the body. It was clear to my mind that we had a large hemorrhage in the skull. Which side was it? You have absolutely no guide in the matter of paralysis in one side or the other—only one trifling guide, which, however, proved of the greatest possible value. Though both pupils were dilated very much, on the left side the pupil responded very slightly to light, but did not respond to light on the other side. I judged, therefore, that upon the right side was the clot and I determined to trephine at once and if I did not find any clot to go up on the other side. The moment I trephined on the right side I found an enormous clot. The brain substance was pushed away from the inner surface of the skull and both the anterior and posterior branches of the middle meningeal were found ruptured and bleeding. The injury was so severe that life could not be carried on and in consequence of it the man died in the course of a few hours. I had used it, not so much by reason of the result as because it illustrates very well how the very fact of that pouring out of blood may make the period of unconsciousness overlap the second and obliterate the intermediate stage and enforce the proper treatment—especially the diagnosis by means of the very slight reaction of the pupil. On the contrary, instead of this intermediate state of unconsciousness being very brief or obliterated, it may be extraordinarily prolonged. Usually we know that it will be two or three hours up to a day or two. A few days ago I had an opportunity to see a decidedly exceptional case of a man in the other direction. A man was thrown off a street railway car directly in front of the Pennsylvania Hospital and received an injury on the left side of the temple. He was taken into the hospital, scarcely unconscious, stunned only. After two or three days there were, it seems, no symptoms which called attention to the fact of the necessity of his staying in the hospital. Six weeks afterwards the man became gradually duller and duller and finally became unconscious. Later when I trephined him on the left side over the anterior branch of the middle meningeal, I found a vast clot extending from the frontal region over to the occipital, where I made, as suggested by Weir, another opening through the posterior portion of the brain and passed drainage through. It was as large a clot as in the first place and I had in that case the happiness of seeing this man recover, although with a somewhat injured condition of his brain. He is slightly aphasic, still in a serious condition and will be all the rest of his life. The two cases illustrate the two extremes of hemorrhage which are so important for us to recognize and for which I think Dr. Fairchild has eminently recommended the proper treatment.

Dr. Angus McLean, Detroit—Dr. McCosh recommended that after laminectomy the patient go without support. I have tried it and find that patients get along as well without the support as with it. I have found much trouble in keeping on a support or spinal brace and think that the heavy muscular tissue there falls back in apposition and protects the posterior portion of the spine quite well.

As to Dr. Eve's paper on spina bifida, I think it is a good step to attempt the closure of the operation without aspirating or injecting fluid, but I think that it would be applicable to just such cases as he had with a small pedicle. I think the judgment of the operator would have to be called into consideration.

The last paper on injuries of the head is an interesting one. Those who fall from a distance or are thrown from a train as compared with those who have had something fall on them, or received a blow upon the head, are injured quite differently. A person receives a direct blow on his head; the force is spent over the vertex. It injures the soft tissue and may fracture and depress a limited portion of the skull. In a case like that, the endocranial contents—the brain tissue—is not disturbed much; the disturbance is more local. A person who falls from a building and strikes his head on the ground produces a general commotion of the cerebrum; the skull is elastic and impressionable; that has been demonstrated by many. The skull can be compressed laterally in a comparatively young person or in a person in middle life from one-quarter to one-half inch. You can put a clamp on the skull and compress it. The lateral walls come together and the tissue within must change; there must be a movement there of the brain tissue. A fall, striking on the head, will lessen the skull's diameter: there is a general commotion and the whole brain tissue is disturbed. An injury like that, without a fracture, is more dangerous than when you have a circumscribed, depressed fracture. You do not know how many small traumata you have there, nor the results. You may have disturbance of the ventricles or an injury to the roots of the cranial nerves or some such thing. Fractures of that kind, from a fall, are usually linear and frequently cross the base. If you take a skull and press it laterally over its opposite sides the fracture will not take place over the points of pressure, but across the base of the cranium, usually in the anterior portion or the portion anterior to the foramen magnum. That portion has a number of cavities and fissures; it is really the weak portion of the cranium.

Dr. Keen went over the different hemorrhages quite well: extradural, subdural and intracranial hemorrhage. In speaking of concussion or compression it is hard to say where concussion ends and compression begins. A slightly depressed fracture may produce compression that will afterwards disappear. Now, you first may have a compression there and, in time, the symptoms of that compression will disappear. In that case some cerebral fluid will escape from the cranium into the spinal canal and lessen the cranial tension. The spinal canal is not a bony canal, but made up partly of fibrous tissue. Where the whole brain enters into the commotion, it is much more serious that a slight tap on the vertex. You can have a much more dangerous lesion without fracture than you can have with a localized, circumscribed fracture and I think those patients deserve to be watched very closely for symptoms which may not show themselves in the first twenty-four hours, but may at the end of the first week; and they should be kept well under observation. I wish to say that in those injuries to the head produced by a fall, where there is much commotion the injury to the brain is to be considered the serious part, and not the injury to the skull.

Dr. Charles H. Frazier, Philadelphia—I should like to bring to the attention of the Section an operation that I would advocate for the relief of tic douloureux, or trifacial neuralgia, a modification of those operations previously recommended, in that it depends for its success upon the division of the sensory root of the ganglion and not on the removal of the ganglion itself. Every surgeon is aware of the difficulties besetting this operation and of the frequency with which operators have been unsuccessful in attempting to remove the ganglion *in toto*. Most all recognize hemorrhage as the greatest bugbear and accountable for the majority of failures and for not a few fatal issues. The most troublesome hemorrhage met with in this operation begins at the time the surgeon attempts to remove the ganglion from its bed and the most alarming hemorrhage may occur at that time as the cavernous sinus may be injured. Any modification of the present operative procedure which relieves the operator of the embarrassment, annoyance and anxiety of hemorrhage is deserving, it seems to me, of some consideration. Granting, for the time being, that the division of the sensory root will, *per se*, effect a radical cure of trifacial neuralgia, the advantages of this over other procedures are evident to all. Chief among them are the following: 1. Generally speaking, its execution is comparatively simple. 2. It reduces to a minimum the most annoying feature of the operation, namely, hemorrhage. 3. The operation is practically complete when the posterior aspect of the ganglion is exposed, a time after which in other operations one begins to encounter the greatest difficulties. 4. The integrity of the cavernous sinus is never in danger. 5. The risk of injuring the sixth nerve is avoided. 6. Lastly, the mortality should be reduced, chiefly because less traumatism is inflicted upon the tissues, less time is required and less blood will be lost. All these conditions should lessen the tendency of shock.

The operation itself resembles those which approach the ganglion through the temporal route, and is conducted as follows: 1. The ganglion is approached by the temporal route, a horse-shoe flap of skin and subcutaneous tissue being reflected with its base line one-half inch below and parallel to the zygoma. 2. Resection of the zygoma. In carrying out the operation upon dogs, in which the field of operation is, comparatively speaking, small, we find it absolutely necessary to remove the zygoma in order to be able to reach the ganglion, and in our work upon the cadaver we find this step in the operation very materially facilitates the approach to the ganglion. 3. Reflection of horse-shoe flap. 4. Removal of button of bone with trephine from an area corresponding to the center of the field exposed. 5. Enlarging opening with rongeur forceps. 6. Exposure of the ganglion by reflection of a flap composed of dura mater and dura propria. 7. Picking up and division of sensory root upon a blunt hook.

We have taken for granted that the effect of division of the sensory root will be permanent. This statement is based upon the assumption that physiological repair of the nerve will not take place at the point of division. To prove this, I began some fifteen months ago, with Dr. Spiller, a series of experiments upon dogs upon which was practiced the operation as above described. After the lapse of varying periods of time, the animals were killed and the specimens removed for histologic examination. Dr. Spiller now has in his possession a number of such specimens and while not yet prepared to make his final report, he has not as yet seen any evidence of regeneration of nerve fibers. Leaving for the time out of consideration what weight the results of these experiments might carry, and drawing an analogy from what we know is the case in the spinal cord, it is reasonable to assume that with the sensory root of the ganglion physiologic repair is more than improbable.

Dr. Robert F. Weir, New York City—There are two things upon which I would like to say a few words. In connection with these brain operations there is one point I consider of great moment about which we should all come to some conclusion, and at which we have not yet arrived. It is easy enough to come to a conclusion with a compound depressed fracture of the skull without symptoms; still more so with symptoms. We think those cases with depression should be operated on. Our distinguished friend, Dr. Agnew, of Philadelphia, went so far as to say that every fracture of the skull had better be operated on. I am not sure but that he is right. My efforts are directed just to that class of fractures where we have a little wound of the scalp and on exposing it, looking at it, and sticking your finger in and feeling it, you find a crack in the bone. You expose it and find a fissure. No symptoms. What are you going to do? Leave it? A little depends as to how the injury was received. If from concentrated violence, you know you had better open that skull, because from such violence the very brittle anterior table is apt to break and you may have danger there far exceeding that on the surface. In many of these cases, you can not learn how the injury was received, or it may have been received by a simple fall on the floor. What should you do then? For many years I did nothing but let it alone; I have lately changed my mind. I have seen many patients who have had subsequent trouble. I have seen many having trouble when I opened the skull, and found there was from this slight fissure the very danger I expected. As an objection to doing this operation or of going through the skull to see what is the condition of the vitreous table, it has been urged that the trauma that you make coming down to the dura will cause adhesions greater than the original injury produced. You know how surgeons have struggled to obviate such adhesions. You must accept the adhesions. Of late years I have felt easier in my mind in going down into these slightly fissured skulls, seeing what the trouble was. I have felt safer and many times my tentative efforts have been rewarded.

The second point is in regard to gaps in the skull, in any of the operations for trephining for depressed fractures of the skull, and particularly if the gaps are of considerable size, and more particularly if the opening in the skull is in a portion of the cranium where it is likely to be exposed to injury; in other words, if it is below the line of the hat or in front where it would be visible. For these reasons I would suggest and advocate the use of celluloid plates either at the time of operation or at a secondary operation. I have resorted to these some eight or ten times and saw one patient only a few days ago who had been wearing a celluloid plate for over six years. So I speak of what I know from personal experience in connection with this device which was suggested by Fraenkel of Vienna. In four operations that I have had, I have done it according to the older method and I see no reason for changing.

What do we gain by this small incision, such as Cushing has spoken of? We have the small operative field; we merely avoid damaging the middle meningeal artery, as it passes across the dura. I do not see the advantage of these small operations. Nay, I say disadvantage. I have done Celsus' operation for division of the nerve at the foramen ovale and the foramen rotundum, which requires division of the zygoma, and I have found after splitting of the zygoma and replacement, we do not always maintain it in place, and it is attended with a considerable difficulty in opening the mouth. So that with the experience I have had in the older operation, I do not feel like abandoning it for one which brings in a risk in another direction.

Dr. Jacob Frank, Chicago—I do not wish to take up the time of the Section in going over the subject spoken of, but I merely wish to speak on a class of cases that Dr. Fairchild considered and upon which at the present time I am making experiments; in the cases that come into the hospitals where nothing can be found, the patients are unconscious, with Cheyne-Stokes respiration, slow pulse, dilated pupils, and we are at a loss what to do. In 1890, at the time that Dr. Keen was tapping the lateral ventricles, I made a tapping of the lateral ventricle for just such a patient, with the delight of seeing the pulse become more rapid, the pupils contracted, respiration normal and recovery follow. Since that time I have had one more case. I was removed from the hospital that furnished me considerable material, and I have not had an opportunity to get any more cases.

I do not agree with Dr. McLean that if the patient is hit on the head it draws the fluid into the spinal column. This was first brought out by a French experimenter a few years ago, when experiments were made with concussion of the brain. Some would say if a blow was received on the head the fluid would proceed to flow. I do not believe it. My theory is this: It is not necessary to receive a blow on the head to become unconscious or to give us symptoms of the concussion. The concussion can just as well be on the spinal column. That is my belief and I hope to prove that at a future date. That is all. (After a pause.)

Since I have tapped the ventricle for these cases, it occurred to me it would not be necessary to do so. I have produced concussions in dogs and led the fluid off by the spinal column just the same as giving injections into the cord. I hope that some of the members who are connected with hospitals where these cases come in, will tap the spinal canal, and I hope to hear reports of the same.

Dr. W. H. Earles, Milwaukee—Owing to the limited time and lateness of the hour, I desire more particularly to address my remarks to Dr. Fairchild's paper. I think the time is here—the indications from the discussions and papers support me in this—when surgical treatment for injuries of the skull must receive greater attention. I am pleased with Dr. Fairchild's paper and wish he was a little more emphatic in his radicalism. I believe any injury to the head that produces a fracture of the skull is also forcible enough to produce injury to the brain tissue itself. If this be true, then it stands to reason that the surgical treatment of fracture necessarily implies that we should, at least, go down to the brain substance or dura mater and ascertain how much injury exists. In other words, on the presumption that there is a possibility of brain tissue being injured, the skull should be trephined and the parts beneath it examined before closing it up. There is no other place in the human body where a surgeon will cover up diseased or injured parts without knowing what condition they are in, except in injuries to the skull. We all know that in injuries where we have cerebral hemorrhages there will sooner or later be symptoms which, in a measure, will direct us to a possible diagnosis, as to the conditions within; but we also know in a great majority of cases the general symptoms give us but very inadequate ideas of the possible injury of the brain substance itself. Therefore, on this point, I desire to be emphatic and I believe it as firmly as I do anything, that where we have a fracture, as a result of traumatism of the head, the plain duty of the surgeon is to ascertain the condition of the brain before closing up the wound.

We occasionally have injury of the head where there is not even a scalp wound and where the patient will die in three or four hours from internal hemorrhage. If this be true, it ought to admonish us that we ought to be extremely careful. Depressed fragments, we all admit, should be elevated, and Keen says that fractures of the internal plate can only be suspected. Now, if you have an injury to the skull sufficient to produce cerebral hemorrhage, where we are inclined to suspect a fracture of the internal plate, it would be poor surgery to cover up the external wound and dismiss the patient without making an effort to trephine and to satisfy ourselves as to the exact conditions. Having taken these steps, we will then feel as though we treated our patients in at least a surgical manner. We believe that the time has come when surgeons will treat every injury to the skull precisely as though they had trouble in the brain substance or coverings. I draw my conclusions, not alone from my own experience, but also from the experience of those who have had a greater number of cases. From an analysis of 76 cases, in my own practice, I have found injury to the brain or its coverings in 87 per cent., and for this reason, as well as for the reasons before mentioned, I believe we should be more radical in the treatment of these cases and not be satisfied with dealing with the outer surface. We should go down to the brain substance to determine the conditions there and feel that we have, at least, discharged our full duty to our patients.

Dr. James E. Moore, Minneapolis—I am very glad to hear the sensible conclusions of Dr. McCosh. I have been on the fence, for while I have not killed any of my patients with fracture of the spine by operation, the after-results have not come up to my expectations. I have seen some improve, but have not been fortunate enough to secure anything like recoveries or satisfactory results. I shall direct most of my discussion to the paper on spina bifida, because I happen to have had some experience in that direction; I have been interested in the prognosis and treatment. The prognosis has much to do with our decision as to treatment. I am free to say that I agree with those who say they do not believe these cases should be treated by injections. I have concluded from my limited experience, that operation should be advised in the large majority of cases. The writer of the paper laid down the limitations of the operation very sensibly. On the whole, I should rather be inclined to be very heroic. I think we should take an advanced position and advise operation in these cases. With reference to the technic, I have had some very interesting experiences. The prognosis after operation differs very materially according to the character of the case. In those cases in which we have a small opening and in which the tumor is covered entirely by integument, the prognosis is good and the operation is almost free from danger. It simply means that you cut down to the pedicle and close up the wound. That is about all there is to it; but unfortunately the majority of our cases are large tumors. We have found from experience, and from the writer, that we can operate on very young patients. I have operated on them under four months of age, removed a tumor as large as the patient's head and, seemingly, with no bad effects from the operation. At first I was very much exercised lest I should cause serious disturbances to the nervous system from evacuating the liquid too rapidly. I was very cautious to empty the fluid slowly for fear of this trouble. In my third case, in attempting to separate the integument from the lining of the tumor, I made a free incision through it and the fluid was evacuated quickly. I had my patient in this case, as I have in all cases, lying on his face over pillows, hips well up, tilted up to an angle of 45 degrees. When I made this incision there was no change in the child's breathing. Chloroform was the anesthetic and there were no bad effects.

The greatest difficulty in the point of technic with me has been to cover the wound securely, to cover the space in the bone securely and eliminate the dead space. I have not thought it wise or good surgery to undertake an osteoplastic flap in a case of this tender age, for that is a bloody, slow operation. If I thought it was necessary to put a solid substance in this space, I would follow the suggestion of Dr. Weir and put in a solid material of another kind—celluloid,—as he suggests. In my later operations I removed most of the lining of the tumor, most of the meninges, taking care to separate the nerve fibers that are on the inside of the membrane. I am not sure that those nerve fibers are of value. I question whether they have much function after they have been bunched down into the wound. I have turned those down and closed the meninges, and then I have dissected the dense soft parts loose from the denser or bony parts and then made a longitudinal incision on either side and approximated these two flaps, bringing them together with chromicized catgut or kangaroo tendon. My only fear has been where I made my longitudinal incisions and brought these flaps towards the center that I would have dead space, but I depended on the blood-clot.

Another interesting point is that we have an ugly, sloughing surface which is very alarming and I have been very successful in securing asepsis by washing that off, gently, swabbing it with pure carbolic acid and then alcohol. I have repeated this process and succeeded in getting aseptic wounds. I have not had the misfortune to have a patient die immediately after this operation. One died suddenly on the second week after operation.

Dr. R. H. M. Dawbarn, New York City—About ten years ago I had the following patient: A man was struck upon the head and did not at once become unconscious, but gradually, in the course of a week, became so, with symptoms of almost complete left hemiplegia. He was carried to the hospital with which I am connected; in the presence of the late Dr. Landon Carter Gray, I operated upon him, going down, of course, over the right motor area. The disc being removed, the dura bulged into the wound; there was no pulsation. Dr. Gray said: "Very evidently there is a clot immediately beneath." I opened the dura and the brain, covered with its pia, bulged into the wound. Still no clot. I took a slender canula and cautiously tapped in six different directions; in three of these cerebrospinal fluid escaped, evidently from the lateral ventricle, and I allowed, I think, fully an ounce to run away, because of the very severe symptoms of compression. But no clot was found, and no way of accounting for the distinct hemiplegia of the opposite side. The man lived about a week and died none the quicker for the operation, but certainly none the more slowly. I remember at the autopsy I found nothing wrong whatever upon the side where he had been trephined; but on the opposite side—that upon which he was paralyzed—was an enormous clot of blood, between the dura and the skull, as big nearly as my entire palm. If I had never heard of physiology and, as a first-year student might have done, operated upon the skull on the paralyzed side, that poor chap might now be alive. I sent the brain, together with the beginning of the spinal cord, to Dr. Gray, who carefully examined them. He found that it was one of those cases in which the motor fibers had not crossed into the medulla, but had gone down each upon its own side of the spinal cord. I discussed it at a meeting of the New York Surgical Society. Those present had known only of one case, Dr. Joseph D. Bryant's, and the latter had only heard of one additional case of the kind in his life.

I have my doubts about the extreme rarity of these things. Anatomists claim it is not so excessively unusual in examining cadavers; but in clinical surgery it is reported with extreme rarity. Perhaps the reason is that when the customary operation gives no relief and the patient dies, an autopsy is generally refused us. Hence, we can not ascertain the true cause of the failure. The family feel that an unnecessary or a useless operation has been performed—perhaps attribute the death to it—and will not permit an autopsy. Should I ever again fail to find the cause of an acute compression of the brain by trephining according to the laws of physiology, I would now remove a second disc from the skull upon the paralyzed side. This would not add much to the danger of the man and we might save a certain number of lives in this way that otherwise would be lost, as was the case just recorded.

Dr. Weir has spoken most interestingly in regard to the use of Fraenkel's method of celluloid. I have brought with me a special plate of modified celluloid, especially made at my request, containing no free nitric acid and with a large percentage of its camphor removed and a little urea substituted, which is being used now. That plate I propose to show before this Section in connection with abdominal surgery; for filling a gap in the abdominal wall, where there is a ventral hernia, where we can not bring the muscular wall together. The skin is, of course, closed over it. In the skull I have repeatedly used this plate to fill bony gaps, and with much satisfaction. In skull work celluloid plates are not new; but whether they remain for years, and indeed, permanently, and cause no irritation, or soften and yield and act as irritants, depends wholly upon that composition. Celluloid, as ordinarily made, contains some free acids still, and will not do. Synthetically made, the urea acid has for some time been employed to give the necessary spring and elasticity, partly replacing the more expensive camphor, and it seems less irritating to the living tissues than using so much camphor. The plate I show resembles closely a piece of ordinary window pane in thickness and general appearance. When boiled it cuts, while still hot, as readily as soft horn. Being transparent one can place it over the gap to be filled and see to mark upon the plate the exact shape of contour desired.

Dr. A. C. Bernays, St. Louis—It seems to me that the paper by Dr. Fenger has opened a wide field, which heretofore is not mentioned in English literature of brain surgery. He proposes, if I understand him correctly, a systematic search for fluid located in the substance of the cerebrum and cerebellum, on both sides of the head. He proposes, I believe, a small trephine hole, to be made over the parietal prominence and through that trephine hole the introduction of a canula into the anterior and into the middle and posterior lobes of the cerebrum. Then, another hole on both sides of the head, through which a short canula can be introduced into the cerebellum, and, it strikes me, gentlemen, that this is an enormously long step in advance of anything that has been advocated in surgery of the brain, and it also strikes me as being important and a well-justified, well-founded step in the right direction. There are undoubtedly cases which the Doctor reported, in which the symptoms led to a well-founded suspicion of an abscess, in which we can not even tell which side of the brain or head is affected.

Now, I want to say one word about the technic of this operation, and there I think the Doctor should have been a little more explicit. It is not necessary to use a large trephine, but a small burr, not over three-eighths in its largest diameter, the hole in the outer plate being nearly twice as large as the one in the inner plate, so that an instrument could be obliquely introduced through that hole, forward, backward and downward, and that was the reason why I took the floor, to suggest that the hole must not be thought of as being a trephined hole in the ordinary sense, but a small hole made by an ordinary dental burr, or one of those instruments which Schwartz uses for boring a little hole into the mastoid process. Systematic search for fluid in obscure cases will, I believe, be rewarded by fine results.

Dr. T. M. Maxwell, Keokuk, Iowa—I had a case in which the whole left side of the skull was crushed. A piece of bone as large as a dollar was removed; he was completely paralyzed on the left side. After dressing the wound, the patient recovered from the paralysis.

Dr. W. J. Means, Columbus—I will confine my remarks to some points concerning the surgical treatment of injuries and diseases of the spine. It occurs to me that the text-books on surgery are too conservative and vague in their treatment of injuries and diseases of the spinal column. The advanced views in this direction taken by Dr. McCosh I believe to be in accord with the experience of most surgeons who have given the treatment of these cases some attention. In the last few years I have had several interesting cases of injury to the spine that have fully convinced me that the so-called conservatism or "do-nothing" treatment should be relegated to the past and more active and intelligent procedures adopted. Early operations on the spine are called for in every case where there is reason to believe from the symptoms that the cord is impinged upon by displaced vertebræ or fragments of the arch. I will also go further and include cases of hemorrhage either intradural or extradural, where the clot is producing paralysis.

The question of determining the extent of the injury—therefore the necessity and propriety of an operation—is one of considerable moment to the surgeon. In abdominal surgery the question of a positive diagnosis before the operation is secondary. The abdominal cavity is opened and the diagnosis made. Sometimes the character of the disease precludes any interference. The opening is closed and the prognosis determined accordingly. A laminectomy is practically free from danger; therefore, when a diagnosis is obscure, no harm can be done by exposing the injured area and determining the true condition. If the cord has been completely severed, no help can be given; the incision is closed and the friends advised accordingly. Unfortunately we are taught that complete paralysis of the extremities and pelvic organs, both sensory and motor, following an injury, means complete destruction of the cord. This is a false premise and should be corrected.

A case of gunshot wound came under my care a few months ago, in which there was complete paralysis of the body below the waist. There was absolutely no reaction to any test applied. Under the *x*-ray the bullet was located in the 4th dorsal vertebra. The bullet had crossed the spine diagonally, lacerating the membranes of the cord and lodging between the pedicles. There was quite a large blood clot and considerable inflammatory exudate around the portion of cord that was injured. The bullet and the blood clot were removed. Within one week after the operation there was some reaction to stimulation in the legs. When the patient left the hospital a few weeks after the operation he had slight movements of his feet and legs, and has since regained considerable power in them. Another case, an engineer on the railroad, had his spine injured in a wreck. I saw him within two hours after the accident, and found him completely paralyzed below the lower dorsal region. There was a deformity over the 10th and 11th dorsal vertebræ. There was no reaction to irritation either sensory or motor. From the symptoms I concluded the cord was severed and thought it unnecessary to operate. The patient was put in the hospital, and the usual expectant plan of treatment carried out. After ten days there was a return of sensation in certain areas followed by limited motion. The patient gradually improved. At the end of twelve months he could walk with crutches. Evidently the cord had not been severed or crushed. I might enumerate several other cases to illustrate the position I have taken, but this will suffice to emphasize the point that it is impossible to determine definitely the amount of injury to the cord from the existing paralysis. In similar cases to the last one I should operate as early as possible.

The second point I wish to make is that where there has been an injury to the spinal column followed by paralysis, and there is good reason to believe the cord is pressed upon by dislocated vertebræ or fragments of bone, benefit may follow an operation though several months have elapsed. The third point is that laminectomy is advisable in diseases of the vertebræ where the necrosis is confined to the arches and processes.

Dr. George W. Crile, Cleveland—I do not believe there is any difference of opinion as to what to do in any case of incomplete paralysis due to pressure upon the cord. But the question as to whether or not you can accurately diagnosticate complete cross lesion of the cord confronts me. I have had two cases in which I have depended on a group of symptoms to diagnosticate total cross lesion of the cord and the autopsy showed there was cross section. At the present time I have a patient who is recovering from the immediate effects of dislocation of the cord, which I believe to be cross section, but from what Dr. McCosh has said I confess to feeling an uneasiness in this case. I have always held to the dictum that the total loss of all the reflexes, of pain, touch and temperature senses below the point of injury, the loss of vesical, rectal and vasomotor tone show total cross lesion. The question then arises, in a given case of total paralysis, below a certain point of injury, whether you can diagnose with accuracy complete cross section of the cord. That, together with the fact that such a large percentage of cases of dislocation of the cord on the immediate reception of injury to the spinal cord the vertebræ spring back again; that if you do operate you can not give any further relief in that group of cases in which the dislocation is so manifest, operation would not be indicated. But I am free to say that, until it is proven that regeneration of the human cord is possible, any diagnosis of a case of cross lesion, if that diagnosis rests on a certainty, would contraindicate operation. Fact is always greater than theory, and I personally feel that my confidence in the theory I have had is shaken.

I would like to ask Dr. McCosh if he found in this case touch, pressure, heat and pain senses abolished, and whether he found an absolute vasomotor paralysis, as well as paralysis of the deeper reflexes in the case upon whom he operated and after the operation the patient grew better?

Dr. A. H. Tagert, Chicago—I wish to report a case of fracture and dislocation of the spine—2d lower dorsal. The patient was anesthetized and extension, counter extension and manipulation used which nearly restored the continuity of the parts. I put the patient to bed with continued extension and counter extension. When the patient regained consciousness the paralysis, pain and numbness were much improved, the man made a good recovery and for ten years has been able to do hard manual labor.

I will also call your attention to one point in fractures of the skull that is sometimes overlooked. The skull is elastic, so if the violence that makes the fracture is sufficient to spring the bone enough to injure the inner plate or admit septic material, we will find some little particles of tissue or foreign substance in the line of fracture. If we examine carefully the line of fracture and find no fragments of tissue or foreign particles therein and no symptoms of injury to the brain, I would let my case go without trephining; but on the contrary, if I found particles of foreign substance in the line of fracture I would certainly trephine whether we had brain symptoms or not. In these cases, as in all others, good judgment will dictate best what to do.

Dr. E. J. McKnight, Hartford, Conn.—On March 23, a man jumped from a moving trolley car and sustained a depressed fracture on the left side of the head. The bones in that vicinity were much broken up. I think there were three or four pieces. It was impossible to tell how much injury was done. The trephine was entered above and on the side; the bones put in good condition and the man made a very rapid and apparently complete recovery, and was discharged from the hospital certainly before the first of April. Later, my service having terminated April 1, he returned sometime during April with a severe headache and temperature, within the twenty-four hours going up to 105, but not regular, sometimes in the morning, sometimes in the afternoon. Dr. Howe explored the vicinity of the original injury and found everything apparently all right. Later the symptoms pointed more distinctly to the brain and a large flap was dissected off. Smaller pieces of bone were entirely removed and a grooved director passed several times into the substance of the brain. After making three or four attempts an ounce and one-half of clear serum was removed, flowing out in the channel of the director. The man made a rapid recovery from that time and was exhibited at our State Society two weeks ago apparently perfectly well. I should use in every case the grooved director. You can pass a probe in the groove as far as you wish, and it seems to me that it is better than any suction instrument.

Dr. S. C. Baldwin, Salt Lake City—My experience has taught me that even in slight injuries of the skull it is well to trephine oftener than we do. We have had some little experience in the hospital in the use of celluloid plates and we were unfortunate enough to have an opportunity to make an autopsy after using one. We found that a large part of the plate had been absorbed and it was as flabby as a piece of silk; it was simply acting as an irritant instead of a protection.

Dr. J. W. Vaughan, St. Louis—I wish to report a case which had complete paralysis below the fifth dorsal vertebra; sensory and motor nerves, bladder and rectum were affected. The patient was operated on. There was some motion under the influence of chloroform; this particular fact was manifest when there was irritation on the right side of the cord at the point where the incision was made. There was motion on movement of the leg on the opposite side. It was five months' standing, complete paralysis, in which he would not be operated; the vasomotor system was interfered with. Five weeks ago to-day that man was operated on and that man has continued to improve slowly, but constantly. There were no two days in succession in which there was not some improvement; so at this time he has motion all along the left leg. There was motion, after operation, in the left leg; some in the right leg, and anterior to this gradually extending down over the abdomen. Sensation is returning over his abdomen, and the last time I examined him there was some sensation over the penis. He can feel some sensation when the bowels are going to operate; that occurred four days ago—and sometimes when urine is withdrawn.

Dr. McCosh, in reply—I would like to lay stress on the importance of early operation in cases of injury to the spine. The mere exposure of the spines and laminæ by cutting through the muscles of the back is a very simple procedure and is attended with practically no risk. If the laminæ be removed the operation becomes somewhat more serious, but still the risk is slight. As regards the treatment of suspected injury to the spine it seems to me that the same rule which we adopt in cases of suspected fracture of the skull applies also to cases of spinal injury, namely, to expose the bone and to ascertain if there be a fracture.

In answer to Dr. Crile's question concerning loss of sensation to touch, heat, and pain, I would say that there was absolute loss of all three functions. As regards the reflexes, the loss of knee-jerks was absolute and apparently of the superficial reflexes as well. As regards the vasomotor disturbances I am not positive. Formerly I have been under the same impression that the loss of tendon reflexes combined with paralysis contra-indicated operation. I have been led, however, to doubt the accuracy of these contra-indications as I have seen quite a number of cases of injury to the cord which have recovered without operation, where in the first hour or two after the injury the reflexes were almost completely abolished or at least were very hard to discover, and yet in a few hours these reflexes gradually returned, and in one or two days became normal. In the case referred to by Dr. Crile the operation was performed very soon after the injury, and it is possible had it been delayed for say eight or ten hours the reflexes might have returned. They were certainly abolished apparently for several hours, and yet one can not argue but that at a later period they would not have returned.

DIABETES MELLITUS IN CHILDHOOD;

WITH REPORT OF A CASE.*

A. C. COTTON, M.D.
CHICAGO.

The following is the history of a case which was first presented at my clinic Feb. 1, 1901:

Ruth M., aged 6 years, 3 months. Family history negative as far as diabetes, gout, tuberculosis and syphilis are concerned. Weight at birth 7 pounds. Was a healthy, plump infant.

Previous illnesses: Summer complaint at 10 months; whooping cough at 2 years, with protracted convalescence, since which time she has had occasional attacks of croup. At 5 years, chicken-pox. At 5½ years measles, from which time—April, 1900—she began to show nervousness, irritability, variable appetite, disturbed sleep and progressive emaciation. In August, it was noticed that she drank enormous quantities of fluids, to which fact her mother attributed the polyuria.

She entered school the middle of September, but was taken out after a few days on account of nervousness and frequent micturition. A physician was called and the child was treated for "nervousness and weakness," without improvement.

Status praesens: (Feb. 1, 1901.) On presentation to the clinic, the patient appeared undersized; weight 32 pounds; weak, anemic, with dry skin, harsh hair and carious teeth. Tongue red and clean, although there has been habitual constipation. Lungs and heart negative. No enlargement of liver or spleen. Very restless and easily fatigued. Extremely sensitive to cold. Pupils normal and no disturbance of vision. Patellar reflex absent. Blood examination showed 3,580,000 reds, 12,000 white cells and hemoglobin 85 per cent., notwithstanding pallor of the skin. Examination of 24 hours' specimen of urine; amount 84 ozs.; reaction acid; specific gravity 1028; thick cloud of albumin, sugar present, one drop giving marked reaction to Haine's test; no casts.

She was put on diabetic diet and pancreatic extract, with sodium salts for relief of constipation. A daily observation was made of the urine, the result of which is appended in the following table.

During the following 5 weeks the quantity of urine passed daily varied from 40 to 104 ounces; the difference in specific gravity, obtained by fermentation test, ranged from 13 to 32, the sugar from 1 1-12 to 6 3-12 oz. or from 2.99 to 7.36 per cent.

Although a grave prognosis was given, the parents were much encouraged by her temporary improvement in strength and weight. The regulation of her diet was but imperfectly observed, owing to parental indulgence, and at times the fluctuations in the urinary findings were coincident with lapses from dietary regimen.

On March 11, she contracted a cold from exposure and developed symptoms which a neighboring physician, summoned hastily, pronounced croup. I saw her the following day and found her with a subnormal temperature, rapid pulse and exaggerated breathing, with crowing inspiration, without cyanosis. There was slight delirium and restlessness, with intervals of partial coma, but no suppression of urine. The next day the crowing inspiration ceased, although the dyspnea became exaggerated. She developed the characteristic "dyspneic coma" in which she died March 14, 1901. No autopsy was allowed.

Date urine was passed.	Amount of urine in 24 hrs. Fl. oz.	Sp. Gr. before fermentation.	Sp. Gr. after fermentation.	Difference in Sp. Gr.	Amount of glucose in twenty-four hours.

How many physicians make the examination of the urine a part of the routine practice in the diagnosis of the disorders of childhood? The fact that analysis of urine is now recognized by the mass of the profession as an essential procedure in the examination of adults may help to explain the recent increase in the total number of diabetic patients reported. If this be true, it may not be unreasonable to urge that the well-known neglect to examine the urine of little patients may partially account for the seeming rarity of this disorder in young children.

The fatality of diabetes during the first decade of life should give to records of vital statistics significant value in estimating the prevalence of this disease in the very young. The essential objection to this method of determining its relative frequency lies in the fact above referred to., viz., the want of accuracy on the part of the attending physician in assigning the cause of death in his report to the registrar.

Most of our standard text-books agree in the statement that diabetes mellitus is rarely found in the extremes of life, but give no comparative figures.

Since vital statistics, as kept by our city health departments, seem to furnish the only information on this subject, the writer begs leave to quote from Dr. H. Stern's "Comments on the Official Records of Mortality from Diabetes Mellitus from the New York Health Department," and also from statistics from the Health

---

MORTALITY STATISTICS WITH REFERENCE TO DIABETES MELLITUS IN CHILDHOOD.

NEW YORK FOR 11 YEARS, 1889-1899.

Total number of deaths from diabetes mellitus	1867
Average per annum	168+
Deaths under 1 year	4
Average per annum	16/44
Deaths under 10 years	24
Average per annum	2 8/44

AGE.	DEATHS.	PERCENTAGE.
Under 1 year	4	0.21+
Under 10 years	24	1.28

CHICAGO FOR 4 YEARS, 1897-1900.

Total number of deaths from diabetes mellitus	418
Average per annum	104½
Deaths under 1 year	3
Average per annum	33/44
Deaths under 10 years	15
Average per annum	3 33/44

AGE.	DEATHS.	PERCENTAGE.
Under 1 year	3	0.71+
Under 10 years	15	3.58

Total deaths from all causes	95,046
Total deaths from all causes under 10 years	37,498
Average deaths from diabetes mellitus (all ages) to total deaths	0.44 per cent.
Average deaths from diabetes mellitus under 10 years from diabetes mellitus	3.58 per cent.
Average deaths from diabetes mellitus in children under 10 years, to total deaths from all causes under 10 years	0.04 per cent.

ETIOLOGY.

Heredity.—That heredity plays a rôle in the predisposition to diabetes there seems to be little doubt, since its history or that of allied disorders, such as gout, tuberculosis and other diathetic disorders in the immediate or remote ancestry is found too frequently to be passed by as a mere coincidence. Thus, Frerichs notes hereditary influence in 10 per cent. of his cases. Seeger in 14 per cent., Bouchard in 25 per cent., as quoted by Von Noorden. Schmitz gives an analysis of 600 cases of diabetes in which 248 were hereditary. The late Dr. Purdy found heredity in 30 per cent. of his cases and states that he has seen diabetes appear in four generations. The same authority quotes Sir William Roberts, who speaks of a family of eight children, every one of whom became diabetic. Pavy mentions a family of seven, four of whom were diabetic. It is even claimed by some that diabetes may be congenital. In support of this, Ballantyne cites a case—reported by W. B. Bell—of glycosuria in an infant of 3 months with diabetic history. Ludwig, also, in 1895, refers to a case of a diabetic mother with saccharin hydramnion surrounding a dead fetus.

Somewhat closely allied to this form may be considered cases of congenital syphilis, in which diabetes may occur as an early complication. Such a case is reported by Lemonnier, in which the diabetes yielded after four months of anti-syphilitic treatment.

The term diabetes mellitus, like that of rheumatism, is employed to designate, not a single constant pathologic process, but probably a variety of deviations from the normal, in metabolism or in organic function. On this account it has been suggested that the name should be exchanged for one more expressive of the pathogenesis. In each instance the particular substitute would depend upon the favorite pathogenic theory of its advocate, whatever that might be, whether alimentary, hepatogenic, pancreatic, neurogenic, bacteriologic, toxic, or plasmolytic. Even though a number of widely differing, separate disorders may be found to have been included clinically under one term, as was formerly the case in "Bright's disease," it still remains that diabetes mellitus expresses the common, most prominent, most pronounced and demonstrated clinical feature of this protean disorder.

Infectious Diseases.—It seems to the writer that the inclination of many to attribute to the infectious diseases of childhood a causal relation to diabetes is not based upon careful analysis of the evidence. Von Noorden, Herrick and others state that an attack of an infectious disease is frequently accompanied by a disappearance of sugar from the urine of diabetics. The same phenomenon has been observed during an attack of jaundice in a child, and Terrien seems to prove in his experiments that the existence of acute gastroenteritis in no way diminishes the glycolytic function. Hence it is argued that a pre-existing glycosuria, discovered through the closer observation during retarded convalescence, may be wrongly attributed to the acute infectious diseases.

Transient Glycosuria.—Many observers admit that any one of the exciting causes may act to produce a transient glycosuria and that the patient, recovering from the disturbance, may subsequently, even after a period of years, develop a serious diabetes.

Dr. Eugene Terrien, referred to above, has found, by injections of sterilized sugar solution into the circulation, that the glycogen storage capacity of the tissues is relatively high in infants. From this it might be inferred that transient glycosuria, at least as far as it is dependent on over-ingestion of carbohydrates, would be of less frequent occurrence in infants than in adults.

SYMPTOMS.

Since the obese type of diabetes is practically unknown in early childhood, an advanced case presents, briefly, a picture of extreme inanition, emaciation, muscular weakness, dry skin and hair, brittle nails, extreme irritability and sensitiveness to cold. The especial symptoms, polyphagia, polydipsia and polyuria are always present.

According to Comby, furunculosis and other skin lesions, common features in adult diabetes, rarely appear in children. This same authority attributes the rareness of the complicating albuminuria to the integrity of the kidneys and greater suppleness of the vascular system in early life. However, in the case cited above, albumin was almost constant while under my observation.

Of the nervous and ocular symptoms frequently associated with diabetes, such as symmetrical neuralgia, neuritis, motor, sensory, trophic or psychic disturbances, amblyopia, cataract, iritis or retinitis, none were observed in the patient whose history is given, with the exception of the diminished knee-jerk and occasional transient pain in the legs and epigastrium.

The disease in childhood is essentially acute. Reports of cases that survive more than a few months are rare.

TREATMENT.

So long as the etiology, and even the pathology, is involved in the obscurity which obtains at present no routine treatment applicable to even the majority of cases may be formulated. Of the many drugs and remedial agents that have found advocates, such as

There are pre-glycosuric indications which should not be disregarded. Then there are attacks of transient glycosuria which should always be regarded with suspicion, for there are cases on record in which diabetes mellitus has developed even months and years after the appearance of a transient glycosuria. Until the lay mind is educated to the point of appreciating the true relation of the physician to the family, namely, that of conservator and supervisor, we shall not be able to make ourselves very useful in such disorders as diabetes mellitus in young children.

ALBUMINURIA IN DISEASE OF THE KIDNEY IN INFANCY AND CHILDHOOD.*

JOHN R. RATHMELL, M.D.

Professor Obstetrics and Diseases of Children, Chattanooga Medical College: Member Staff Erlanger Hospital.

CHATTANOOGA, TENN.

Diseases of the kidney in infancy and childhood are not so varied as in adults. They are chiefly active hyperemia and nephritis following the contagious diseases, especially scarlet fever. The acquired diseases of the kidney in childhood show considerable difference from adults, because acute affections, common to childhood, causing diseases of this organ, are seldom met with in after life. Under 15 years of age there is less likelihood to disorders of circulation than in later periods, and consequently under this age they are less likely to have chronic lesions of the kidneys.

Again, a child's kidney rapidly recovers from an injury. It is very rare to find a case of pyelonephritis, or hydronephrosis in children. But cachectic conditions lead to amyloid infiltration and this, in turn, to chronic albuminuria in children as well as in adults. Physiological albuminuria may occur at any period of infancy or childhood, but it is the most common between the ages of 5 and 15. The albumin is rarely present in the urine passed in the morning immediately on rising. Albumin alone being present, with an absence of blood corpuscles or other abnormal elements, indicates an absence of pathological changes.

While albumin in the urine does not, of necessity, indicate serious organic disturbances in the kidney, neither does it necessarily render the prognosis of a grave character, yet its presence, however slight, commands the utmost watchfulness and care before a decision is reached as to its being of no clinical significance. Albuminuria is the escape of serum-albumin and serum-globulin from the blood vessels into the renal tubes, and this escape of albumin indicates slight or grave nutritional disturbances. One is scarcely able, however, to certainly locate the site of these disturbances. For in each kidney it is estimated that there are about fifteen miles of tubing. This tubing is lined with basement membrane covered by epithelial cells of a variety of shapes and sizes. It is probable that the very shapes and sizes of the cells are accounted for, not by any peculiar function they each possess, but by the fact that they fill in the lumen of a tube that takes on the form, in quirk and curl, of almost every geometrical figure, from the capsule of Bowman to the excretory duct of Bellini. Yet it is thought that the columnar cells of the tubes of Henle select the urea, though this has not yet been certainly proved. While the tests for albumin and the use of the microscope will show disturbances, somewhere along the tubal track, yet nothing will appear that absolutely locates the lesion.

CAUSES OF ACUTE AND CHRONIC NEPHRITIS.

The scheme given here has been of much use to myself in locating the first appearance of the trouble and in giving the causes. It seems to me that it covers the whole field, as follows: The nutritional disturbances lie in the epithelium lining of the glomeruli, the tufts of capillaries, and the uriniferous tubules.

1. Renal Congestion.—Active: chronic liver, heart, pregnancy; passive: tumors.
2. Definite Lesions of Kidney.—Toxemia, scarlet fever, gout, amyloid and fatty degeneration, renal suppuration, renal tumors.
3. Indefinite Causes.—Scurvy, syphilis, medicinal poisoning, kidney, pregnancy of, epilepsy, tetanus, injuries to head, apoplexy, exophthalmic goiter.
4. Accidentals.—Pus: cystitis, pyelitis, urethritis; blood: pelvis, ureters, bladder.
5. Febrile.—Typhoid fever, smallpox, yellow fever, diphtheria, scarlet fever.
6. No Definite Lesions.—Functional, dietetic, intermittent, cyclic.

Albumin is found in the urine after a rich meal, heavy muscular exertion, intense emotion, or cold bathing. The cyclic variety bears upon life insurance. However, when every other constituent of the urine is normal, the case under careful management ordinarily recovers and the life insurance people sometimes accept the risk. I care not how little stress may be laid on the so-called functional albuminuria, the cyclic variety, or what not, undoubtedly some changes, though apparently trifling, do take place in the kidney somewhere. Fortunately, however, for the patient, these changes are non-progressive. But sooner or later, it may be after months or years have passed, grave lesions will show themselves, and insidious degeneration has been going on in the meantime. So for no other reason than that a certain relief may come to the mind of the physician, it becomes a necessity for him to determine, by differential diagnosis, whether he is dealing with a case of renal albuminuria or functional albuminuria.

I desire to report the case of a child, where the cause of the disease is somewhat uncertain. Early in March, I was called in consultation to see a little boy 4 years old, who in development would ordinarily be taken to be 7. He had a very large head, large body and large limbs. At the age of 12 months, I was told, he weighed forty pounds. The history of the boy is that he was never sick until the beginning of this illness. He never had the diseases common to children, such as scarlet fever, measles, whooping cough, etc. The preceding Christmas time, he seemed to be indisposed and it was observed that his eyes and face and lower extremities were edematous. A physician was called and treated him for a few days, when the child apparently recovered. Two or three weeks later he became sick again, with the same symptoms. An examination of the urine showed the presence of a large quantity of albumin.

When I saw the patient, the albumin was about two-thirds of the bulk of the urine. The specific gravity was 1040, the color dark, and the amount plentiful. The temperature was normal, eyes almost closed from the swelling, the face also very much enlarged, and the feet, ankles and lower extremities very edematous. The abdominal cavity was ascitic, the hands and arms were swollen, while the pulse was fair but showed consider-opium, bromids, antipyrin, sodium salicylate, alkalies, etc., few, if any, have met with the approbation of more than a very limited number of clinicians. With perhaps the exception of opium, which seems to retard the progress of the disease, and alkalies to counteract the "acidosis" and impending coma, the benefits of drug therapy are admittedly restricted to rare, exceptional cases. Against the high rate of mortality from this disorder in childhood, the limited utility of opium affords but a modicum of encouragement as to help from medicaments. The prolongation of a life, with the establishment of the opium habit at its threshold, is not sufficient compensation.

---

* Read at the Fifty-second Annual Meeting of the American Medical Association, in the Section on Diseases of Children, and approved for publication by the Executive Committee of the Section: H. E. Tuley, Edwin Rosenthal and Samuel W. Kelley.

At the present time the regulation of diet seems to be the most important therapeutic measure and by far the greater number of important improvements have been attributed to diet.

That the severe form is the one most frequently seen in early childhood is acknowledged, and the rapid course of the disease, rarely influenced by therapy, is the experience of all. The death certificate follows hard upon the diagnosis. If from this gloomy outlook concerning the prognosis in early childhood there be one ray of light it seems to the writer that, for the present at least, it must be sought along the lines of prophylaxis.

It is now believed that diabetes, if not an hereditary disease, at least develops along the lines of a somewhat positive diathesis. To the extent that the function of the family physician is supervisory over his patients, may he hope to avert such disorders by controlling their development through attention to hygiene, in order that the young, whose immediate or remote ancestry show diabetes, gout, tuberculosis, neuroses, or even syphilis, should be sedulously guarded. Dietary errors, such as ingestion of food beyond the child's capacity for absorption and assimilation, preponderance of saccharin substances, as sweetmeats, confections and pastries, must be carefully avoided.

That the elimination in these little patients is of the utmost importance receives additional significance when we consider that some observations emphasize autoinfection and reinfection as an etiologic factor. It is of interest in this connection to mention that injection of feces as well as the urine of diabetic patients in lower animals will reproduce glycosuria. A thorough care of the digestive tract, including the teeth, is all important. So, too, the care of the skin and respiratory organs, that elimination by the former and oxygenation through the latter may attain the highest possible perfection. Adenoids should receive attention, as well as other evidences of lymphadenitis and struma.

Especially should we protect these children from mental strain, shocks, frights, trauma and exposure to inclement weather, since cases are reported in which the development of glycosuria was preceded by such disturbance.

In a child thus carefully observed, diabetes may be anticipated by the appearance of pre-glycosuric signs, such as incontinence of urine, muscular debility, irritability, with progressive emaciation in spite of voracious appetite, even though a single test of the urine fail to reveal sugar. The importance of an early diagnosis is evident, for it is admitted that success in treatment bears an inverse ratio to the previous continuance of the disease.

The utmost care of the diet and hygiene is even more important in children than in adults, since a higher ratio of metabolism is essential to growth in addition to repair. But the child will not bear radical dietary changes well. Hence, though so important, the reduction of carbohydrates should be gradual. The same may be said of the augmentation of fats, when indicated. Finally, too much stress can not be laid upon the importance of protecting the child from a sudden lowering of the temperature.

DISCUSSION.

Dr. C. F. Wahrer, Fort Madison, Iowa—When a school teacher, I had a peculiar pupil. He was a genius in spelling, but that was about all. He was finally apprenticed to a blacksmith. One day the boss sent him out to measure a wagon body, and the boy reported that its length was "8 feet 16 inches, and the length of the hammer handle, and so much," indicating a position on the hammer handle. This is about our position in regard to our knowledge of diabetes. I wish to speak in regard to a too emphatic treatment and dietary. Those who need the most enlightenment on this subject are, however, not the ones who come to these meetings, but those who stay at home and neglect even such simple measures as making analyses of urine. When young students in medicine we think we know something about diabetes. We have a few medicines which control the output of sugar in the urine, and perhaps also reduce the polyuria to some extent, but still we are unable to get at the root of things. Nearly all of these cases of diabetes mellitus die. I believe there are very few cases on record in which children under 10 years of age, suffering from true diabetes mellitus, recover. Why, then, take away from them the few things which they can eat and enjoy, and insist upon their eating things which it requires a strong stomach to digest. I do not condemn dietetic treatment by any means, but I object to the adoption of a routine treatment which may be more disastrous than the disease itself. Let us show mercy, and think carefully before we do things which are tyrannical or even cruel. I have a child who had scarlatina in connection with three of his brothers and sisters. The first child attacked was extremely ill, but the child I am thinking of was only moderately sick. All of these children made a very fair, and I may say, an uneventful recovery. This child was a boy who, with the exception of a tendency to obesity, was healthy in appearance. In the early part of August it was noticed that he often arose at night to go to the water closet. For a few weeks I paid no attention to this report, but then an analysis of the urine showed over 5 per cent. of sugar. I corresponded with many medical men, but received no more light than we have to-day. The case terminated fatally without any severe manifestations of the disease aside from those referable to the urine. Two weeks before death the boy enjoyed greatly a hunting trip, but he suddenly became very ill after it, and died after three days of diabetic coma.

Why diet and treat so radically that which we do not understand? Many who take no treatment whatever live just as long as others do. I do not want to disparage conservative treatment.

Dr. Cotton, in reply—Of course, there is much that might be said on this subject, for no doubt we have all had interesting individual experiences. I must say that I consider myself somewhat of a failure in the effort to arrest diabetes in children. The dietetic theories which have been advanced are quite confusing, but I am convinced of the importance of watching diabetic children.

The authorities quoted in the paper seem to me to show very clearly their belief in hereditary tendencies. Thus Purdy asserts that he is satisfied that he has found a hereditary element in fully 30 per cent. of cases. If the true function of the family physician ever comes to be fully realized, and he becomes medical supervisor of the family, he must take into consideration everything which shows a predisposition to diabetes. In this way it is not improbable that he may prove of great value in stopping diabetes before it has become thoroughly established.

There are pre-glycosuric indications which should not be disregarded. Then there are attacks of transient glycosuria which should always be regarded with suspicion, for there are cases on record in which diabetes mellitus has developed even months and years after the appearance of a transient glycosuria. Until the lay mind is educated to the point of appreciating the true relation of the physician to the family, namely, that of conservator and supervisor, we shall not be able to make ourselves very useful in such disorders as diabetes mellitus in young children.

ALBUMINURIA IN DISEASE OF THE KIDNEY IN INFANCY AND CHILDHOOD.*

JOHN R. RATHMELL, M.D.

Professor Obstetrics and Diseases of Children, Chattanooga Medical College: Member Staff Erlanger Hospital.

CHATTANOOGA, TENN.

Diseases of the kidney in infancy and childhood are not so varied as in adults. They are chiefly active hyperemia and nephritis following the contagious diseases, especially scarlet fever. The acquired diseases of the kidney in childhood show considerable difference from adults, because acute affections, common to childhood, causing diseases of this organ, are seldom met with in after life. Under 15 years of age there is less likelihood to disorders of circulation than in later periods, and consequently under this age they are less likely to have chronic lesions of the kidneys.

Again, a child's kidney rapidly recovers from an injury. It is very rare to find a case of pyelonephritis, or hydronephrosis in children. But cachectic conditions lead to amyloid infiltration and this, in turn, to chronic albuminuria in children as well as in adults. Physiological albuminuria may occur at any period of infancy or childhood, but it is the most common between the ages of 5 and 15. The albumin is rarely present in the urine passed in the morning immediately on rising. Albumin alone being present, with an absence of blood corpuscles or other abnormal elements, indicates an absence of pathological changes.

While albumin in the urine does not, of necessity, indicate serious organic disturbances in the kidney, neither does it necessarily render the prognosis of a grave character, yet its presence, however slight, commands the utmost watchfulness and care before a decision is reached as to its being of no clinical significance. Albuminuria is the escape of serum-albumin and serum-globulin from the blood vessels into the renal tubes, and this escape of albumin indicates slight or grave nutritional disturbances. One is scarcely able, however, to certainly locate the site of these disturbances. For in each kidney it is estimated that there are about fifteen miles of tubing. This tubing is lined with basement membrane covered by epithelial cells of a variety of shapes and sizes. It is probable that the very shapes and sizes of the cells are accounted for, not by any peculiar function they each possess, but by the fact that they fill in the lumen of a tube that takes on the form, in quirk and curl, of almost every geometrical figure, from the capsule of Bowman to the excretory duct of Bellini. Yet it is thought that the columnar cells of the tubes of Henle select the urea, though this has not yet been certainly proved. While the tests for albumin and the use of the microscope will show disturbances, somewhere along the tubal track, yet nothing will appear that absolutely locates the lesion.

CAUSES OF ACUTE AND CHRONIC NEPHRITIS.

The scheme given here has been of much use to myself in locating the first appearance of the trouble and in giving the causes. It seems to me that it covers the whole field, as follows: The nutritional disturbances lie in the epithelium lining of the glomeruli, the tufts of capillaries, and the uriniferous tubules.

1. Renal Congestion.—Active: chronic liver, heart, pregnancy; passive: tumors.
2. Definite Lesions of Kidney.—Toxemia, scarlet fever, gout, amyloid and fatty degeneration, renal suppuration, renal tumors.
3. Indefinite Causes.—Scurvy, syphilis, medicinal poisoning, kidney, pregnancy of, epilepsy, tetanus, injuries to head, apoplexy, exophthalmic goiter.
4. Accidentals.—Pus: cystitis, pyelitis, urethritis; blood: pelvis, ureters, bladder.
5. Febrile.—Typhoid fever, smallpox, yellow fever, diphtheria, scarlet fever.
6. No Definite Lesions.—Functional, dietetic, intermittent, cyclic.

Albumin is found in the urine after a rich meal, heavy muscular exertion, intense emotion, or cold bathing. The cyclic variety bears upon life insurance. However, when every other constituent of the urine is normal, the case under careful management ordinarily recovers and the life insurance people sometimes accept the risk. I care not how little stress may be laid on the so-called functional albuminuria, the cyclic variety, or what not, undoubtedly some changes, though apparently trifling, do take place in the kidney somewhere. Fortunately, however, for the patient, these changes are non-progressive. But sooner or later, it may be after months or years have passed, grave lesions will show themselves, and insidious degeneration has been going on in the meantime. So for no other reason than that a certain relief may come to the mind of the physician, it becomes a necessity for him to determine, by differential diagnosis, whether he is dealing with a case of renal albuminuria or functional albuminuria.

I desire to report the case of a child, where the cause of the disease is somewhat uncertain. Early in March, I was called in consultation to see a little boy 4 years old, who in development would ordinarily be taken to be 7. He had a very large head, large body and large limbs. At the age of 12 months, I was told, he weighed forty pounds. The history of the boy is that he was never sick until the beginning of this illness. He never had the diseases common to children, such as scarlet fever, measles, whooping cough, etc. The preceding Christmas time, he seemed to be indisposed and it was observed that his eyes and face and lower extremities were edematous. A physician was called and treated him for a few days, when the child apparently recovered. Two or three weeks later he became sick again, with the same symptoms. An examination of the urine showed the presence of a large quantity of albumin.

When I saw the patient, the albumin was about two-thirds of the bulk of the urine. The specific gravity was 1040, the color dark, and the amount plentiful. The temperature was normal, eyes almost closed from the swelling, the face also very much enlarged, and the feet, ankles and lower extremities very edematous. The abdominal cavity was ascitic, the hands and arms were swollen, while the pulse was fair but showed considerable arterial tension. There was considerable loss of strength, and a great loss of red blood. In fact there was present the condition known as the "alabaster cachexia."

---

* Read at the Fifty-second Annual Meeting of the American Medical Association, in the Section on Diseases of Children, and approved for publication by the Executive Committee of the Section: H. E. Tuley, Edwin Rosenthal and Samuel W. Kelley.

The diet in this case was nothing but sweet milk as long as he could take it, but after awhile his repugnance to milk became so great that he could scarcely swallow it. Then some stale bread was put in the milk, and he was also allowed some fruits in the form of oranges and lemonade. In some types of albuminúria, white meats may be given, namely, fish, chicken, turkey, sweetbread, birds, etc. In the way of vegetables, spinach, oyster plant, parsnips, etc., may be allowed. In the way of fruits, stewed apples, prunes, pears and peaches are sometimes used. But milk, two or three pints daily, is the food *par excellence.*

By way of treatment in this case, the wet pack, epsom salts and cream of tartar, a solution of the citrate of magnesia and vichy water, also a solution of the lactate of strontium, and Basham's mixture were used. The albumin ran from 1 to 2 per cent. In ordinary cases it runs from only 0.16 to 0.5 per cent. The specific gravity continued at 1040. The scrotum and penis were edematous to a very great degree. The eyes remained puffed and the arterial tension high. From time to time the urine was examined microscopically and pus, blood, and a few epithelial and hyaline casts were found. The history and progress of the case pointed to a chronic parenchymatous nephritis, immediately following an acute nephritis, a condition rarely found in children. This child died about ten days thereafter, from uremia and pulmonary edema.

Another case in point is that of a little boy 5 years old. His home was in Lookout valley. He had whooping cough the winter previous to my seeing him in July. The disease left him with albumin in the urine, in large quantities. I was called as consultant in July and found him in the home of his brother, a physician on Lookout Mountain, about 20 miles from Chattanooga. He had been carried thither by his parents, who hoped that the change, from the valley to the top of the mountain, would improve his condition.

He was very edematous over the entire body. The penis and scrotum were enormously swollen. He was voiding but little urine, which was heavily loaded with albumin and of a high specific gravity. The heart was weak but not diseased, the breathing shallow, and he was able to take but little nourishment of any kind. His principal longing was for fruit. The attending physician had used the customary means of treatment, excepting the hot wet pack. This was recommended by me, as was the use of the solution of the lactate of strontium, which was given in as large doses as the child would bear. Another suggestion was also carried out, and that was to take the child back to his home in the valley, thus hoping to give the skin a chance to aid in reducing the accumulated fluid. After taking him home, the attending physician reported that improvement began promptly and recovery rapidly ensued. After six months he told me that his little brother had fully recovered so far as he was able to discern.

The prognosis, in both of these cases, was grave on account of the aggravated symptoms and the age of the patients. They are of interest, however, in that the general symptoms and age were about the same. But in the one case the cause of the kidney involvement could not be determined, while in the other the cause was attributed to the whooping cough. In the first case, however, we might ascribe the cause to cold and wet weather, but it has been observed that exposure to inclement weather very rarely gives rise to acute degenerative nephritis.

As the prominent symptoms in these cases are albumin, high specific gravity and edema, I want to state that these symptoms are especially found in interstitial and chronic parenchymatous nephritis, active hyperemia, catarrhal nephritis, parenchymatous degeneration, passive hyperemia, and acute nephritis. In acute nephritis the amount of albumin depends upon the extent of involvement of the glomeruli, and the amount of casts depends upon the extent of the tubules affected.

A word about edema in renal disease. As this is a common symptom, it has always puzzled me to explain, to my own mind, the cause of its presence. Edema is the accumulation of watery fluid from the blood vessels, into cellular tissues and lymph spaces. Several theories have been advanced in explanation of this. 1.—the original theory was that, because there is an accumulation of the daily quantity of urine, the tissues are saturated with the water not excreted by the kidneys. 2.—Edema is the cause rather than the result of diminution. 3.—Transudation is due to the changes in or injury to the endothelium, increasing the perviousness of the blood vessels. None of these theories are fully tenable because the etiology and pathology of edema have not been satisfactorily explained. Hence, another theory was pronounced by Landerer, which is, that the relaxation of the tissues and loss of elasticity prevent the forcing of natural lymph into circulation, and as a result, a watery infiltration of the tissues ensues.

To meet and treat the symptoms of edema and ascites requires some thought concerning the condition of the patient. Of the three kinds of expellants, namely, diaphoretics, diuretics, and cathartics, the latter are indicated when general edema and threatening uremia exist. They are more certain in their action. Podophyllin, 1-10 grain, may be given repeatedly to a child 5 years old. Compound jalap powder, 5 to 10 grains, may also be used. A bath, 105 to 110 F., with the child wrapped in a woolen blanket, may be given for fifteen or twenty minutes. Then remove the child, take off the wet blanket and wrap in dry, hot blankets until reaction sets in. You may also add muriate of pilocarpin, in doses of 1-20 of a grain, by the mouth, to a child of 2 years, or hypodermically, to one 5 years old. Where ascites is extreme, tapping is of value. Teaspoonful doses of infusion of digitalis, every four hours, to a child 5 years old, is best.

TRAUMATIC AFFECTIONS OF THE UVULA

SEYMOUR OPPENHEIMER, M.D.

Laryngologist to the University Medical College Dispensary: Instructor in Laryngology at the University Medical College: Consulting Laryngologist and Otologist to the Hebrew Sheltering Guardian Society.

NEW YORK CITY.

From its peculiar position in relation to the oropharynx the uvula would appear to be extremely susceptible to severe traumatic influences, as it is constantly subjected to minor traumatisms in deglutition and excessive vocal efforts, yet reported cases of damage to this portion of the pendulous palate are comparatively rare, the text-books containing little or no reference to traumatic affections. The anatomic structure of the uvula, and its mobile characteristics, render it to a great degree exempt from traumatism otherwise affecting the tissues in its immediate proximity. The mucous membrane covering it, especially at the tip, is of firmer consistency than that of the surrounding tissues, and is also less dense in structure. As an additional protection against damage from the lodgment or impact of foreign bodies, is the absence of glandular stomata or crypts, as occur on the pharyngeal walls and tonsils.

Pathologic alterations of the contour and structure of the uvula, as the result of traumatic influences, may best be classified from an etiologic standpoint, and may be divided into five classes. The first being extensive injury, the result of forcible contact with resisting foreign bodies, the soft tissues of the uvula being caught between the foreign body and the pharyngeal wall; the second class embraces those cases in which the mucous membrane is pierced by a minute body, such as bristle or stiff hair; the third class embraces the more frequent cases in which, as the result of swallowing caustic materials, and also in the application of caustics to adjoining regions, the uvular tissues become subjected to chemical traumatism. The fourth class is seen in accidental cases, in which this portion of the palate is subjected to traumatism as the result of operative procedures directed to the tonsils, larynx or nasopharynx, the uvula accidentally becoming engaged in the handle of the forceps, or whatever instrument of similar nature is being used. The fifth class results from indirect traumatic influences, being by far the most important from the standpoint of the individual as it occurs in singers as the result of excessive or ill-advised efforts at vocal exercise.

As illustrative of the amount of damage that may be done to the uvula as the result of forcible contact with a hard, resisting foreign body, the following case is presented:

C. J., a colored male, aged 30 years, was seen Feb. 23, 1899, when he presented the following history: While under the influence of alcohol and smoking a corn-cob pipe, he ran against a stone wall, on the evening previous to which he was seen. The stem of the pipe was violently forced into his throat and severe pain and bleeding ensued, lasting the entire night. The pain was intense, referred to the base of the tongue and pharynx and presented the taking of food, either solid or liquid; even the mere act of swallowing being impossible on account of the increase of pain produced at such times. The pipe had been held on the left side of the mouth and examination showed a deep laceration on the same side of the tongue and, after inflicting this damage, the stem of the pipe had evidently passed backward and jammed the uvula against the posterior pharyngeal wall. The uvula was perforated directly in the median line, 2 millimeters below its junction with the soft palate, the perforation being partial inasmuch as it did not go through the mucous membrane of the posterior aspect and corresponded in shape and size to the stem of the pipe. Inflammation and edema were severe and prevented to a great extent the opening of the mouth, but hemorrhage had spontaneously ceased. The parts were painted with ichthyol and an astringent mouth wash given, with prompt relief in a few hours, patient making uninterrupted recovery in a few days.

It is of interest to note that in cases of severe traumatism of the uvula edema is not as well marked as in apparently more trifling injuries, scarification rarely being necessary, as free bleeding has already taken place and the amount of swelling is limited. Another point of interest is the rapid improvement without the least suggestion of septic infection, following the use of antiseptic and astringent applications. It is also remarkable in the cases of severe local injury with what rapidity the healing of the lacerated or punctured wound takes place; this case, being typical of its class, well shows this marked recuperative power, as in forty-eight hours after the patient was first seen all the symptoms had disappeared and but slight congestion remained around the wound.

Of more frequent occurrence than severe lacerated or punctured wounds of the uvula are the minute lacerations of the mucous membrane, and oftentimes of the deeper structures, as the result of small foreign bodies, such as a bristle from a tooth-brush, etc. Belonging to this class is a case reported by Fisher,[1] in which the uvula was pierced by a bristle; severe hemorrhagic infiltration occurred, the uvula being greatly swollen and dark purple in color from the large amount of blood effused into the tissues. Small foreign bodies producing traumatic injuries of the uvula may induce pathologic alterations seemingly out of all proportion to their size. When the foreign material, such as a minute fish bone, merely enters the surface epithelium and does not penetrate into the deeper tissues a slight grade of inflammation results, dependent on the length of time the foreign body remains *in situ*, and then rapidly disappears without further treatment as soon as the offending particle is removed. The subjective symptoms are, however, most annoying, as the patient complains of the presence of a foreign body even for a considerable time after all traces of it have been removed, and the dysphagia, peculiarly, is very rarely referred to the uvula directly, but most frequently to the tonsillar or epiglottic regions. The characteristic features predominating, when a minute sharp-pointed body enters deeply into the uvular structures, are edema and extravasation of blood. The uvula becomes enormously increased in size and, as a rule, hemorrhagic extravasation of the uvular tissues is nearly always of traumatic origin.

The general symptoms of the varied traumatic inflammations of the uvula are, in the majority of cases, not well marked, except when the traumatism is severe, when the inflammatory reaction involves the adjacent parts by continuity of structure and pharyngitis results, attended with a moderate degree of temperature, such as occurs in the regular course of acute non-specific inflammations of this particular region. Within a few minutes or hours after the infliction of the injury, and dependent upon its extent, the patient complains of a sense of pharyngeal discomfort, which may in severe cases, as in the one reported here, amount to intense pain. The pain is constant, but becomes markedly exaggerated during deglutition, and food is refused for a limited time until the acute symptoms subside. Dependent on the amount of edema and inflammatory reaction are the changes in the voice. The functions of the uvula are for the time abolished, the resonating capacity of the parts is impaired, and articulation becomes thick from the swelling of the uvula and from the increased amount of mucus collecting in the oropharynx, due to indirect stimulation of the secretory glands. On account of the increased amount of saliva and mucus, there is a constant desire to swallow, this also being enhanced by the sensation of the presence of a foreign body which seems a constant local symptom in practically all cases. This foreign body sensation, in a few instances, may be due to the presence of a minute particle of adventitious material partially embedded in the mucosa and, from the constant motion and enlargement of this part, the tissues in its immediate locality are irritated by the foreign matter abrading their surface with every act of swallowing, thus keeping up the inflammation. In the majority of cases, however, this is but a nervous element, but in all, careful search under good illumination should be made, and any adventitious material immediately be removed.

Dyspnea only occurs when the tissues are enormously increased in all their dimensions by the effusion of blood or serum into the structure of the uvula; it may be extreme, requiring immediate operative procedures, as in a case reported later in the course of the paper, and is also present in the class of cases where the traumatic influences are indirect, as in excessive vocal strain. The non-appearance of dyspnea, when the uvula is subjected to direct and severe traumatism, is readily explained by the laceration of the tissues as a result of the foreign body, allowing the fluids to escape, and in this manner excessive infiltration by liquids is prevented. Cough is not as commonly present as the other symptoms mentioned, and is rarely complained of when the parts are edematous, as in this condition the increase in the size of the uvula is one of bulk, that is, in the lateral direction, while the cough factor depends on the elongation of the tissues and the contact of its tip with the epiglottis. When cough is present, however, it is of an irritating, tickling variety and promptly disappears on the application of an astringent, so as to draw the elongated uvula away from the larynx or base of the tongue.

Acute uvulitis, characterized by the presence of a considerable amount of local edema, may result from the inadvertent swallowing of boiling water, acids, ammonia or any chemical irritant, the uvula participating in the general inflammation of the oropharynx. Cases in which the traumatic effects of irritant chemicals are alone limited to the uvula are much more frequently observed, and occur as the result of ineffectual or unskilful attempts to cauterize the adjoining tissues for therapeutic purposes. Under these circumstances but a limited portion of the organ is involved, although the resultant edema and inflammatory reaction is far in excess of the amount of damage inflicted. J. Solis-Cohen[2] reports a case where caustic applications produced an intense edematous condition of the uvula, and numerous other cases similar in character have been recorded in the literature. The loose structure of the upper two-thirds of the uvula, like that of certain portions of the larynx, renders it susceptible in a marked degree to the action of caustics, and it is surprising in what a short period of time, after a minute amount of caustic material has been inadvertently applied, the edema develops.

Injuries, the result of carelessness or accident during operations on the pharynx or larynx, are of more or less frequent occurrence, especially when the electrocautery or tonsil snare is used without proper precautions as regards the protection of the surrounding tissues. The resultant burn differs but little from that due to the action of chemical caustics when the traumatism is the result of the careless application of the electrocautery, while minor wounds due to catching the uvula in the joints of instruments are usually of little moment, except as they to a moderate degree augment the inflammatory reaction and for a short time cause the patient added discomfort. Objectively, when the uvula is injured by being caught in instruments during operations in this locality, we find a small laceration or bruise of the mucous membrane the most common feature, while traumatic ulcers the result of caustics are apt to develop in a few days after the injury has been inflicted, but readily heal under appropriate treatment. The liability to local and circumscribed sepsis after the infliction of this class of injuries upon the uvula, seems to occur more frequently than as the result of other forms of traumatism, as the injury, when due to instruments, is usually of a contused and lacerated variety and the resultant ulcer develops as the result of septic infection through the buccal cavity. Especially is this noticeable should the patient have decayed teeth and the parts be not thoroughly cleansed, as is frequently the case, before any operative procedures are instituted.

The first four varieties of traumatism, to which the uvula may be subjected, are all the result of direct violence to this portion of the oropharynx, while the fifth form results indirectly from excessive strain of the parts and the symptoms are out of all proportion to the apparent amount of injury inflicted, the ill-regulated column of respired air and the irregular muscular action combining to produce this variety of indirect traumatism. The following case illustrates in a forcible manner this form of traumatism, and is reported by Le Jeune[3]. He was hastily summoned to see a female singer, who was supposedly choking to death. The intense dyspnea came on after she had been singing for a time and immediately followed extreme and prolonged efforts to reach a note beyond her compass. The subjective symptoms were dyspnea, with the sensation of a foreign body in the throat. The uvula alone was affected and was of a dark purple hue and the size of an olive. Incision was immediately made, and gave exit to blood, which had extravasated into the tissues of the uvula; immediate relief was given the patient.

In a similar manner small submucous ecchymoses are produced by excessive and violent efforts to clear the throat, as in the act of hawking. The effects of this form of traumatism upon the voice, both singing and speaking, is marked; the range is lost, as is also the clearness and strength, and often it becomes tremulous until the uvula regains its normal tone.

No special forms of treatment are indicated when the uvula suffers as the result of traumatism, but when the tissues are lacerated, the local application of ice is most gratifying in conjunction with antiseptic and mild astringent applications. While in inflammations the result of inadvertent applications of caustics or instruments in operative procedures, bland soothing applications are valuable, such as ichthyol in weak solution. When edema is extensive, or the parts much enlarged from hemorrhage into the tissues, and dyspnea becomes imminent, multiple incisions promptly relieve all threatening symptoms and the uvula rapidly regains its normal size.

Clinical Reports.

TWIN CONCEPTION.

J. PROSSER HARRISON, M.D.
RICHMOND, VA.

The lady referred to in this report is a Virginian, white, 42 years old, married eighteen years; has had seven pregnancies to the full term, all of the children living, and three miscarriages at two, four and six months. She was taken unwell on

November 29 last, and the usual symptoms of pregnancy progressed without incident until May 30, when she felt a sudden gush of water from the vagina, followed by quite a severe hemorrhage. I confined her to bed for ten days, and there being no further symptoms she got up and went about her usual household duties. On July 4, she had two sharp pains in her abdomen and went to the closet to relieve her bladder, when in her words, something passed from her, but was not detached, and, being afraid to pull on it, she supported it to the bed, where I found her about half an hour later. I found a fetus expelled and cord attached; used gentle traction and then quite forcible traction, without result; introduced my finger and found os sufficiently dilated to introduce three fingers, and felt head of living child: followed the cord along the right side of uterus as far as my finger would reach, and, finding no attachment, used considerable force and detached the cord. There was no hemorrhage, no discharge, no pain; in fact, no symptoms. I kept the patient in bed. The fetus was about three months growth; genitals sufficiently developed to distinguish the sex (male); head about the size of tennis ball, and compressed flat. There was no decomposition, no maceration. It looked as if it had been immersed in alcohol.

On July 7, the mother was delivered of a seven-month girl after a normal labor. After delivering the placenta, I introduced my hand, but found no second placenta. After washing the placenta I found a portion of it, outside the membranes, as large as my hand, presenting the same appearance as the expelled fetus. There is no doubt in my mind that this was a twin conception, and not a superfetation, for there was only one placenta. The mother made an uneventful recovery; the child is well and growing.

A CASE OF PRIMARY RETROPERITONEAL SARCOMA.

RICHARD R. SMITH, M.D.
SURGEON TO BUTTERWORTH HOSPITAL.
GRAND RAPIDS, MICH.

The following case of retroperitoneal sarcoma is reported because of its rarity. The extremely softened condition of the tissues was unusual, perhaps unique. In Steele's[1] summary of the literature of the subject he found 22 cases, or 35 per cent. of the total number of cases reported were cystic, and in 15 of the 22 the degeneration a hemorrhagic one, the center of the softened growth being filled with a dark brown fluid or semi-fluid material. This softening was so extreme in the case here reported as to make it impossible to name its exact origin. That it started in the upper retroperitoneal space was apparent. The case also presented many of the objective symptoms of a pancreatic cyst, which makes the case of interest in considering that affection.

T. A. D., male, aged 27, farmer, gave no history of syphilis or gonorrhea. He had good health until the spring of 1900, when the left scrotum gradually became swollen, and in August it was tapped and fluid removed by Dr. Asa L. Taylor, his family physician. After this, the hydrocele filled again and then the fluid disappeared spontaneously. In September the patient began to have pain in the hypogastrium; anorexia, distress after eating, belching of gas and occasional constipation occurred, and he had to give up work. Dr. Taylor, who examined the abdomen several times at the beginning without finding anything abnormal, on November 10 noticed a tumor, which increased rapidly in size up to the time of operation, November 30. One week before operation the patient became jaundiced, this condition increasing rapidly. The stools were clay colored and the urine very dark. He vomited several times in the three weeks previous to operation and the pain in the hypogastrium was quite severe.

Examination.—Man of fairly good physique, fairly well nourished, severely jaundiced and no marked cachexia present. The examination of the heart and lungs revealed nothing abnormal. Pulse ranged between 70 and 80, and temperature between 99 and 100. Examination of scrotum shows right testicle much smaller than usual, but otherwise apparently normal. Patient thinks it has diminished in size since last summer. Left scrotum evidently contains some fluid and the epididymis feels hard and nodular but not enlarged. Abdomen is flat. Just above navel and to the left is a slight bulging. A tumor can be distinctly felt here extending slightly below, two inches to the left of the median line and about an inch to the right. It is globular, fairly hard, non-fluctuating but slightly tender; does not move with respiration, and is tympanitic on percussion. Its most prominent portion seems to be just above and to the left of the umbilicus. Tumor shelves off rapidly into the depths of the abdomen. Liver and spleen dulness normal. Exploratory operation advised.

Operation.—Abdomen opened by vertical incision an inch to the left of the median line, extending one and a half inches above and the same distance below the umbilicus. The omentum presented, seemingly very much engorged with blood. The transverse colon lay just below the most prominent portion of the tumor. In attempting to get down to the tumor, the hemorrhage was profuse: then there was a sudden welling up of blood from the depths. The transverse colon and omentum were pushed quickly upwards and the tumor gotten at from below. It was seen that the blood came from a hole in the tumor, the thin walls of which were grasped and drawn through the incision. The hemorrhage had been profuse and it was some minutes before it was controlled by packing. It was not deemed advisable to attempt to bring the sac through the mesentery on account of liability to hemorrhage, and it was stitched to the abdominal wall, the omentum and transverse colon being pushed upward. The sac was packed with gauze. The patient was severely shocked, from the severe loss of blood, but rallied within a few days. Bile passed with the first movement of the bowels and jaundice disappeared completely in about two weeks. The general condition seemed to improve for a while, but the improvement was only temporary. He lost flesh rapidly and died four weeks after operation. The emaciation towards the last was very rapid. About two weeks previous to death, there appeared a bulging just above the incision. This pushed forward with remarkable rapidity, finally pushing the sac from the abdominal wall where it had been stitched and at death presented at least two inches above the surface of the abdomen. The mass oozed blood almost constantly, and in the last two days in large amounts. Patient complained a great deal of severe pain in the back for the last two weeks. Bowels were moved with great difficulty.

Postmortem.—Lungs and heart presented nothing abnormal except some fresh adhesions about the base of the left lung. The tumor mass projecting above the surface of the abdomen consisted of semi-solid material, mostly blood-clots, and a gray, mushy, partly organized material throughout. This mass occupied a cavity running back to the spine, then upwards, filling the left renal space and pushing the kidney outward and extended down to Poupart's ligament. It was surrounded everywhere by intestines firmly agglutinated but apparently not involved. The transverse and descending colons were pushed upward and outward against the wall of the abdominal cavity. In the structure of the left testicle was a small hard mass, which was removed for examination.

Report of Pathologist.—Organized pieces of the tumor were removed from several parts of the growth. Sections of some of these presented the appearance of a small round-celled sarcoma with a small quantity of stroma. In other sections taken from near the periphery there was much more fibrous tissue and many blood vessels. The tumor may be classed as a small round-celled sarcoma undergoing degeneration, which is so frequently met with in this class of malignant growths.

The nodule removed from the testicle was examined and found to be composed of fibrous tissue. There was no evidence of its being associated in any way with the abdominal growth.

Professor Howntze, a Danish physician, stated at the Congress of Scandinavian Surgeons, that he had cured several cases of cancer by freezing them.

SATURDAY, SEPTEMBER 7, 1901.

THE NATURE AND THE CAUSE OF PUERPERAL ECLAMPSIA.

At the Ninth Congress of German Gynecologists at Giessen, May 29-31, 1901, eclampsia constituted one of the subjects for an exhaustive general discussion, which was introduced by Fehling and Ryder.[1] Inasmuch as this discussion probably represents quite fully the present views concerning the nature and cause of eclampsia it may be of some interest to briefly review the principal facts and opinions brought out.

In his report on the pathogenesis Fehling announced the following theses: Puerperal eclampsia is a distinct and characteristic process, which occurs only in the period of gestation. There is no special form of placenta, no special form of renal or hepatic disease in eclampsia; it is not necessarily connected with ureteral dilatation, but albuminuria is almost always present. There is no definite pathological anatomy of eclampsia. That it is contagious has not been shown, and there is no proof of Bouchard's claims that it is caused by an increased toxicity of the plasma of the blood associated with diminished or absent toxicity of the urine. Eclampsia is neither an hepatotoxemia nor a leukomainemia. The lesions of eclampsia are associated with the presence in the blood of some coagulative substance. Finally, eclampsia is an intoxication of fetal origin.

A very important contribution to this discussion is Schmorl's report on the pathological anatomy based on a thorough study of the organs in no less than 73 cases. From the results Schmorl finds that the process has a fairly definite pathological anatomy, thus invalidating one of Fehling's theses. When the whole complexus of morbid changes are considered one must agree with Schmorl. The kidneys without exception are the seat of albuminous and fatty degenerative changes with more or less necrosis. These changes affect the secreting tubules and occur in varying degrees of extent and intensity. Thrombosis is frequent in the glomerular capillaries, as also in the arterioles and veins. Ureteral dilatation is of no greater frequency than in the non-eclamptic. In three cases there were hemoglobin infarcts and hemoglobinemia, but the exact cause could not be determined. In the liver there are albuminous changes in the cells, and hemorrhagic and anemic necrosis were present in 71 cases. In the two cases in which they were absent there was total thrombosis of the main stem of the portal vein. These necroses, when small, are situated in the peripheral parts of the lobules and invariably accompanied with thrombosis of the inter- and intra-lobular capillaries and often also of the larger vessels. The necroses do not stand in any relation to the severity of the symptoms, and they are not due to traumatism during the convulsion, because there may be very few in cases with many and severe convulsions and very many in cases with few and light seizures. In addition to secondary pneumonic processes, the lungs showed thromboses and hemorrhages in 66 cases. Fat embolism was also frequent, the source of the fat being, it is thought, the bone marrow, the subcutaneous tissue and possibly also the fat tissue in the pelvis. The most constant changes in the brain are small softenings and hemorrhages, especially in the cortex, but also in the brain stem and in the lenticular nucleus. Thrombosis and possibly increased blood pressure during the convulsions are regarded as the cause of these changes. In the heart are degenerative changes, hemorrhages, necroses, and thrombi, but the latter are not as common as in the other organs.

Schmorl does not attach any special importance to embolism of parenchymatous cells in eclampsia. Even placental cell embolism are not distinctive because it occurs in non-eclamptics. Schmorl is no longer disposed to attribute to placental cells the ability to liberate coagulative substances. He has not seen any other disease with the complexus of changes outlined in the foregoing. While no single lesion is absolutely characteristic or pathognomonic, the sum total of all the changes is as distinctive as in many other diseases. From the nature of the lesions he would assume that a peculiar substance enters the blood and leads to multiple thromboses. Whether this substance comes from the placenta or from the fetus can not be settled at this time. Possibly the applications of the principles of cytolysis may throw some light upon this dark problem.

It is regrettable that careful and complete systematic bacteriologic examinations do not accompany this valuable report which is based upon such a wealth of observations. The relations of bacteria and bacterial products to thrombosis are of such importance that they surely merit consideration in connection with eclampsia; and the clinical picture and pathological anatomy of eclampsia do not of themselves definitely exclude a microbic etiology. Indeed, Albert advances the theory that eclampsia is a microbic intoxication from the decidua.

Strassmann deals with the question of the why and the when toxic substances are retained in case eclampsia is a toxic disease. Kundrat and after him Herzfeld advanced the theory that abnormal divisions of the abdominal aorta may result in such displacements of the ureters as to subject them to compression. The frequency of eclampsia in primiparæ and in twin birth, in contracted pelvis, and the fact that the attacks may cease after delivery, point to the influence of mechanical conditions. He could not find, however, after an exhaustive investigation, any relation between puerperal eclampsia and anomalous division of the aorta.

---

[1] Report in Centralbl. f. Allg. Path. u. Path. Anat., 1901, xii, 635-648.

In the same discussion considerable reference is made to physical and chemical conditions of the blood and urine in eclampsia. Füth and Krönig found that the maternal and fetal blood have the same osmotic tension and specific gravity, showing that if there are toxins in the maternal blood they do not cause increase in its tension or its gravity. Dienst observed an increased amount of fibrin in both the bloods in pregnancy, and he assumes that during pregnancy a certain amount of poison is produced in the fetus and taken into the maternal blood where it may accumulate in fatal quantities in case elimination is interfered with. Schumacher established that the urine of eclamptics is no more toxic than normal puerperal urine of the same concentration. He regards the toxicity of eclamptic urine when concentrated as dependent entirely upon its hemolytic properties due to its different tonicity from that of the serum of the blood. Schroeder notes that the freezing point of urine in eclampsia falls below healthy urine and sometimes below that of the blood. As the attacks pass away concentration increases, but the observations are not sufficiently extensive to permit any definite conclusions. In connection with this question reference may be made to the article by Stern[2] in which he discusses osmotic pressure in its relation to uremia.

Veit did not find the maternal serum hemolytic for the blood cells of the fetus nor the fetal serum lytic for the maternal corpuscles. By inserting syncytial cells from the rabbit into the abdomen of geese the serum of the geese acquired the power of dissolving the placental cells of the rabbit—a placentolysin or syncytiolysin developed. Normally but few syncytial and placental cells enter the maternal circulation; should a larger number enter, lysins with toxic properties might develop, but Veit adduces no further evidence in favor of this idea.

Taking it all in all we must admit that eclampsia is a toxic disease in which coagulative substances exist in the blood, but the source of these substances has not been determined. No decisive proof is at hand to the effect that the intoxication is of fetal origin.

NOCTURNAL ENURESIS IN CHILDREN.

Incontinence of urine may result from a variety of causes, but the principal and underlying factor resides, of course, in a relative or absolute weakness of the sphincter of the bladder. This may at times be in a sense conservative, as in the so-called incontinence of retention, when the bladder having become filled and distended to its utmost, the sphincter yields, and urine escapes. Irritation of the walls of the bladder in consequence of inflammation, the presence of new growths or foreign bodies, excessive acidity of the secretion of the kidneys, may result in involuntary discharge of urine. This may take place, further, during states of unconsciousness—even during sleep—and in the presence of various diseases of the nervous system, partly as a result of indifference and partly as a result of anesthesia or paralysis. The control of the urine is a voluntary function, and it is developed in a growing child as volition is evolved—sometimes earlier, sometimes later, in accordance with individual conditions and training.

There is reason to believe that the involuntary discharge of urine that takes place during the night, and sometimes also during the day, in some children, at a time when control of the sphincter of the bladder has usually been acquired, is a neurotic manifestation involving the sensibility of the mucous membrane, or the motility of the muscular coat of the bladder, or both, and Dr. Martin Thiemich[1] expresses the opinion that the disorder is of hysterical origin. He points out that the peculiarity of hysteria in children is its monosymptomatic character. From the study of a considerable number of cases he found that the majority of children suffering from enuresis were the offspring of neurotic parents, so that both heredity and environment contribute to the development of the neurosis. In fact, in many cases a history of enuresis in other members of the family could be elicited. Further, the involuntary discharge of urine not rarely becomes attended with or replaced by other symptoms of hysteria. Finally, the epidemic occurrence of enuresis, in schools and the like, is not unknown, and the best remedy under such circumstances has consisted in isolation.

Neither is the treatment generally employed opposed to the hysterical origin of enuresis. In this connection suggestion plays an important rôle, and mechanical or physical measures—especially the application of the faradic current—are more efficient than medicinal measures. A strong current to the point of causing pain should be employed, and it is a matter of indifference where the electrodes are applied, although it is customary to apply one in the neighborhood of the bladder. Subcutaneous injections of strychnin may likewise be employed, and be made either in the vicinity of the bladder or in some indifferent situation. Adenoid vegetations in the nasopharynx should, if present, be removed, and any local condition, such as preputial adhesions, hyperacidity of the urine, and the like, should be corrected.

THE MULTIPLICATION OF BOOKS.

On account of the rapid increase in the number of books the large library in Paris has been forced into new and larger quarters in order to find room for the rapidly accumulating literary treasures it is intended to house, classify and arrange in an accessible manner. The librarian is reported to have stated that it is becoming a more and more serious problem to properly house and arrange the books. If the present rate of increased production continues it will be but a short time before still larger quarters will be absolutely essential. He emphasizes particularly the difficulties of classification and practical arrangement. The overproduction is so excessive that the large libraries are threatened with perpetual and hopeless chaos in their efforts to make the vast accumulations accessible to their patrons. The transitory character and even absolute worthlessness of a large proportion of the publications are pointed out, and the remedy suggested is that writers restrict their production to the greatest possible minimum. The real literature is on the point of being buried beneath a mass of cheap trash. "One can not see the woods for trees."

---

[2] THE JOURNAL, July 27, 1901, p. 256.

[1] Berlin.-Klin. Woch., 1901, No. 31, p. 808.

This excessive literary production is characteristic also of medicine. The number of journals, of reprints, of books, and of printed matter issued from various sources is simply overwhelming. The transitory nature of the larger part of this material is so apparent as to need no emphasis at this time. Real, honest literary study of a fairly popular topic in current medical literature is rendered exceedingly irksome and laborious, because of the vast quantity of rehash and compilation without the addition of a single original idea or suggestion. It is practically out of the question to be in touch with all the literature issued in any one department of medicine, because of the expense and time it would involve to attempt to master the stuff sufficiently well to separate the wheat from the chaff. Not only are lengthy articles produced in large numbers, but they are frequently printed in two or three different places and reappear again and again under various disguises and modifications.

All sorts of medical societies attempt at great expense to issue some form of transactions or proceedings in which they too often simply reprint articles and reports that have appeared already in current periodicals. This custom seems to be spreading also to hospitals and laboratories, which reissue in the form of reports material previously printed. Surely there is a great deal of paper and printer's ink wasted to no particular good purpose in these days, acknowledge though we must that this productiveness betokens scientific activity and interest in medicine.

Some one has characterized America as the land that flows with ink and money, and the first ingredient is certainly liberally used by the medical profession here. The same is true of the medical profession abroad, possibly to a greater extent than here in some respects. In the interest of higher standards and greater concentration and accessibility of our medical literature an appeal must be made to the self-criticism of those who write. Let not your literary activity be measured by the number of papers and addresses printed each year, or by their length, but solely by the quality. And when publishers tempt you to cover again some well-trodden field, yield not!

AUTHORS AND MEDICAL SUBJECTS.

A novelist tells the story that in writing his latest work he called in his family physician to assist him in duly disposing of one of his characters and—here comes the special point of his tale—he received a bill for professional services for the same. While we did not learn the exact state of the author's mind when this occurred, it would appear from his reporting the event that he considered it somewhat extraordinary. Why this should be so is not self-evident unless it be that it seemed to him that doctors could deal only with actualities, and was not aware that medical opinion on fictitious cases has a legally recognized value and is constantly being called for in the courts. The service rendered in this case can hardly be questioned—certainly not when one recalls the too common medical mistakes of writers of fiction. The curious thing is, that the writer who had the sense to call for such aid should have not appreciated its money value.

BOVINE TUBERCULOSIS.

According to a printed interview, Dr. J. G. Adami, the distinguished pathologist of McGill University, while not endorsing Professor Koch's almost absolute denial of the communicability of bovine tuberculosis to man, yet thinks him nearer right than his critics. Among these he includes Lord Lister, Drs. McFadyean, Bang and Nocard. It is, in his opinion, just as extreme an assertion to say there is imminent danger of the transfer in all cases of the animal disease to our species as it is to unqualifiedly deny this, or to consider the peril an altogether negligible quantity as does Koch. For two years he says he has been working on this question in connection with Drs. C. F. Martin and C. Higgins, and apparently his opinions heretofore expressed as to the difficulty and infrequency of such transmission, and the weakness of the evidence of its occurrence have not been changed to any extent by these later researches. Adami's opinion as well as Koch's will carry weight, and together are alone enough to cast a cloud over the universal validity of the generally accepted medical dogma of the danger of bovine tuberculosis to man.

ST. LUKE'S HOSPITAL AGAIN.

A subscriber writes us regarding the notorious St. Luke's Hospital and enclose circular letters, facsimile of diploma, etc., received by him from that institution, and says: "This abominable fraud is being sent out to hundreds of practitioners. . . . On looking over the names and degrees of the 'staff' one would be led to believe that it is one of the most eminent in the whole country." The doctor goes on to state that he writes to urge us to expose it and that it is the duty of medical journals to warn their readers of the swindling concern, etc. We have called attention several times to this Niles (Michigan) scheme for "working" physicians, and we doubt if any regular readers of The Journal of the American Medical Association are possessors of their "beautiful diplomas." We can hardly believe that any intelligent physician who acted deliberately could now be duped by the "eminent" names, though their affixes are imposing enough at first sight. They certainly seem varied enough to satisfy the most liberal minded, including as they do representatives of all schools, with osteopathy thrown in. They only need a few Dowieites, "Christian Scientists," and other voodoos to make the assortment complete. Besides the great Granville, who heads the list, and presumably manages the concern, we see the name of the redoubtable Zwigtman Van Nopper of Independent Medical College fame, who, it is said, toured through India leaving a trail of Armstrong diplomas behind him. After all, the question is whether the doctor who buys one of these certificates and hangs it in his office for the purpose of impressing his patients with the idea that it means something of which he might be proud, is not practicing deceit just as much as the ones who sold him the parchment. While it hardly seems necessary to warn honest physicians against the concern, the attention of the Michigan authorities is again respectfully called to its existence.

THE PHILIPPINE INSULAR BOARD OF HEALTH.

The Philippine Commission has not neglected one of its chief duties, namely, attention to public health, a greater necessity in a tropical country even than in a temperate climate. Without positive knowledge as to the details of previous laws, it is yet safe to say that there has been much needing reform in this line, certainly this is so as regards the practical application of sanitary rules. Manila is already a very different place in this particular from what it was under former control, and the continuance of the good work is provided for, not only for the chief city but for the islands generally, by the enactment of a law constituting and providing for an Insular Board of Health, having full supervision of sanitary matters and vital statistics. The latter is also authorized as well to regulate and disseminate information on sanitary subjects among the people, to draft and recommend suitable laws, including those governing the admittance to the practice of medicine and has also authority to prosecute all violators of the sanitary regulations. The Board is composed of the commissioner of public health, who is chairman a sanitary engineer, a chief health inspector, the superintendent of the government laboratories, ex-officio, and a secretary; all, except the sanitary engineer and the superintendent of laboratories, are specified to be duly qualified physicians. The chief surgeons of the Army and Marine-Hospital Service, and the president and vice-president of the Association of Physicians and Pharmacists of the Philippine Islands are also honorary members, but without the right to vote. Another enactment provides for government biologic, chemical and vaccine and serum supplying laboratories to act as adjuncts to the health authorities as well as for such other purposes, agricultural, economic, etc., as may be required in the development and betterment of the country and its resources. It is evident that the present government of the Philippines is not one of mere politicians. It is to our interest as well as that of the Filipinos that scientific sanitation is carried out in the islands and there appears to be no danger at present of any serious failure in that respect.

Medical News.

CALIFORNIA.

Smallpox, *diagnosed as chicken-pox and Cuban itch,* and the patients not quarantined has resulted in at least forty cases of the disease in the Elsinore valley.

Sanitary Recommendations.—Health Officer O'Brien of San Francisco, in his annual report, urges the use of individual drinking cups in the public schools, and the proper fumigation of telephone transmitters, which he considers, "are admirably adapted for the harboring of bacilli."

Trolley Rides for Convalescents.—Dr. Matthew Gardner, chief surgeon of the Southern Pacific Railway Company, has arranged with the Market Street Railway Company, San Francisco, to provide a special car every Monday, in which the convalescent patients of the hospital are given a ride for three or four hours.

Personal.—Dr. F. P. Conac-Marquis was appointed chief surgeon of the French Hospital, San Francisco, August 25, vice Dr. F. Dudley Tait.——Dr. P. C. Remondino, San Diego, has filed a petition in bankruptcy.—Dr. W. J. Bauer has been appointed resident physician of the 26th Street Hospital, San Francisco, vice Dr. Victor E. Putnam, resigned.

CONNECTICUT.

Dr. John J. Wagner, Greenwich, was injured in a runaway accident August 25, breaking his leg.

Personal.—Dr. John H. Billings has resumed the practice of his profession in Middletown.——Dr. Charles W. Page has retired from the superintendency of the Connecticut Hospital for the Insane, Middletown, and will spend the winter in Hartford and go to Europe in the spring.

Examination of School Children.—Drs. Alfred G. Nadler, Percy D. Littlejohn, Jeremiah J. Cohane, Frank A. Kirby and Edwin P. Pitman have been appointed examining physicians for the public schools of New Haven. For the time being they receive no salary, but it is hoped that the value of the service rendered may impel the Board of Finance to make an appropriation that the work may go on.

ILLINOIS.

Smallpox.—Coal City has four cases of sickness which has been pronounced smallpox by the official of the State Board of Health sent to investigate the matter.

Dr. George A. Lierle, Payson, was injured by the overturning of his buggy, August 14, sustaining a fracture of the skull and severe contusions of the chest and back.

Gift to Bloomington Hospital.—Abram Brokaw and his wife have given $10,000 to the Deaconess Hospital, Bloomington, on the condition that the institution be thereafter known as the Brokaw Hospital. The trustees have accepted the conditions and the money.

Peace at Elgin.—Members of the Woman's club look on the action of the physicians with favor. They assert, that in organizing, the doctors simplify matters and make possible an adjustment. The general feeling now is that instead of a preparation for concerted action against the Woman's club the organization of the physicians may be interpreted as an extension of the hand of fellowship.

Personal.—Dr. Roy B. Roberts, Brooklyn, has located for practice in Augusta, succeeding Dr. Chalmer R. Hecox.——Dr. Robert L. Frisbie, Baileyville, has been appointed attending physician at the Home for the Feeble-Minded, Lincoln.——Dr. James W. Smith, Cutler, has moved to Baldwin.——Dr. John T. Lloyd, Pulaski, has moved to Baldwin.——Dr. John C. Kirby, Verona, has located in Morton.

Chicago.

An Examination for District Physicians was held by the County Merit Board, September 4.

Operation at County Jail.—What is said by the lay press to have been the first operation for appendicitis performed in a jail in the United States, was made on a prisoner charged with murder, August 27, by Dr. Francis W. McNamara.

A fire at the County Hospital, August 27, caused a little damage, threatened for a time to destroy the hospital and created a panic which was quieted only after great efforts by the attendants under the personal direction of Warden Healy.

War on Quacks.—The attorney for the State Board of Health announces that the Board is about to take active measures for the suppression of the quack doctors, dispensaries and medical institutes "whose advertisements enrich the daily papers and attract the ignorant masses. Several individuals have been summoned on the charge of practicing medicine without license and the first cases are set for September 9.

Smallpox in Chicago.—The August 31 issue of the Weekly Bulletin of the Health Department states that for the first time in more than thirty months the City Isolation Hospital was emptied of smallpox patients last week. Between March 9, 1899, the date of the first case of the series, and August 12, 1901, the date of the last admission, 342 cases of smallpox were discovered in the city, and removed to and treated in the Isolation Hospital. The last case was discharged, recovered, August 28, the resident physician relieved from duty, and the hospital closed. During the period a total of 960,588 persons were examined as to their vaccinal status by the medical inspectors of the Health Department and the public vaccinators, and 220,648 were vaccinated. The greatest number in any one month was 303,725 examined and 44,904 vaccinated in February, 1901, since which time the disease has steadily declined until the city is now free from the pest. This is a very gratifying contrast to the exhibit made by other large cities of the country.

New Rules for County Hospital Staff.—Warden Healy of the Cook County Hospital has issued the following rules as a guide for attending physicians and surgeons, internes and nurses: "Transfers must be reported immediately to warden by interne in charge of patient at time transfer is ordered by attending man. Notice of emergency service and transfer cases should be immediately telephoned to attending surgeon and the particulars of the case given to party answering telephone. Operation blanks must be filled out each day and filed in the warden's office before 9 o'clock the following morning. Duplicate operation blanks must be left with the warden every Saturday before 5 o'clock p. m., for the use of the attending surgeon. The junior surgeon must make the final preparation of patient before operation, both in and out of clinic. The senior surgeon should not be permitted to make such preparations, as it greatly endangers the aseptic result. Instruments, needles, sponges, etc., at operations should be handled entirely by the nurses. Senior internes are directed to comply with and enforce orders and instructions of attending surgeons and physicians as to prescribed treatment for patients assigned to their service, and report to the warden any neglect of patients by nurses or junior internes. They will pay strict attention to rule governing the discharge of patients before 12 o'clock m. each week day. Train cases will be taken to Dunning on Mondays, Wednesdays and Fridays. Ambulance cases Tuesdays and Saturdays. Dunning cases should be reported to the warden's office the night preceding their discharge.

INDIANA.

Dr. J. C. O'Day, Montpelier, has moved to Bradford, Pa.

Dr. Herbert O. Statler is about to move from Goshen to Kalamazoo, Mich.

Medical College of Indiana.—The new $20,000 addition to this institution is nearly completed. It is a three-story building, the lower floor of which is to be used in connection with the Bobbs Free Dispensary. The second floor will be arranged for society halls and the third will be utilized for laboratory and microscopical work.

Insanity Trust Report.—The State Board of Charities today filed a report with the Governor on the investigation of the insane hospitals to ascertain if any sane persons are deprived of freedom. The report says no such persons are confined, and have not been within the last sixteen months, unless in the case of one patient, who probably recovered after he was found insane and before he was received at the hospital, a period of fifty-three days. The report says: "It may be proper for us to suggest that the effort to connect the 'insanity trust' with the hospitals was unfair to the institutions."

KENTUCKY.

Dr. William H. Forgy, Fairview, has disposed of his practice and will move to Pembroke.

Dr. Archibald H. Barclay, Lexington, knocked out a footpad who attempted to rob him, August 25.

Shows and Circuses Quarantined.—The Bowling Green Board of Health met, August 29, and adopted a resolution, establishing a quarantine "against all traveling shows or circuses of any kind coming into and showing in the city of Bowling Green or within two miles of said city limits within thirty days from date.

Conclave Medical Committee.—Under the efficient generalship of Dr. T. Hunt Stucky and the intelligent co-operation of his special medical aids and medical corps numbering ninety-one, the medical arrangements of the Knights Templars' Conclave at Louisville were as nearly perfect as they could be made. Eighteen litter corps stations were established and six ambulances were on duty.

MARYLAND.

Personal.—Dr. William H. McCormick, of Cumberland, celebrated the fiftieth anniversary of his marriage, August 28.——Dr. William H. De Courcey, of Queen Anne's County, is at Bedford Springs, Pa.——Dr. E. Williams, of Anne Arundel County, has gone to Boston.

Smallpox Epidemic Predicted.—The health authorities think that the approaching winter promises a wider prevalence of smallpox in the United States than the country has experienced in thirty years. All signs, they say, point that way, and the local boards of health are urged to take due notice and guide themselves accordingly. The vaccine physicians are instructed to visit the schools on the opening day and vaccinate all who need it. School boards are advised that there is urgent need of rigid enforcement of the vaccination law. Two cases of smallpox have appeared at Cooksville, Howard County, both in negroes. A large number of negroes have come in contact with the cases, and considerable anxiety is felt. Prompt vaccination, isolation and disinfection have been instituted. It is said the State Board will bring action against those responsible for not reporting the cases promptly as required by law.

Baltimore.

Personal.—Dr. H. B. Eggers is at Bridgeton, Pa.——Dr. Alfred Whitehead has gone to the Exposition, and will also visit Canada and the Adirondack Mountains.——Dr. Arthur O. Brickman is at the Blue Mountain House.——Dr. J. D. Fiske is at Atlantic City.——Dr. H. J. Carrick has gone to the Buffalo Exposition.——Dr. F. R. Rich is at Cape May.——Drs. C. C. Peebles and L. Gibbons Smart are in Lancaster County, Pa.——Dr. Isham R. Page is at Cape May.——Dr. John N. Mackenzie is at Narragansett Pier.——Dr. George Reuling has returned from Narragansett Pier.——Dr. M. H. Carter has gone to the Exposition, Niagara and Canada.——Dr. Robert Hoffman has returned from Berlin.——Dr. J. C. Hemmeter is in Montreal.——Dr. T. Chew Worthington is at Atlantic City.—Dr. J. E. Heard is at Dinsmore Beach, Md.——Dr. W. Tunstall Taylor has gone to Boston.

MASSACHUSETTS.

Personal.—Dr. Warren K. French has opened an office in Worcester.——Dr. J. Oswald Vogel has located at Mount Bowdoin.

A hospital for crippled children is to be established on Bumkin's Island off Hough's Neck in Hingham Bay, through the munificence of Mr. A. C. Burrage, who has secured a long lease of the island from Harvard University.

In Memoriam.—The Eastern Hampden Medical Society, at its meeting in Springfield, August 22, passed resolutions in memory of two recently deceased members—Drs. Harry A. Merchant, Monson, and Joseph T. Pero, Indian Orchard.

Italians Spread Malaria.—In the annual report of the State Board of Health Secretary S. W. Abbott says that during the last ten years every case of malaria investigated in Massachusetts has been traced to the presence in the neighborhood of Italian laborers.

Lowell Demands Isolation Hospital.—Agent Knapp, in behalf of the Lowell Board of Health, sent a letter, August 10, to the State Board of Health, asking the latter to take measures to compel Lowell to build a contagious hospital as required by the statutes. The reason is the prevalence of diphtheria and the insufficiency of accommodation.

MICHIGAN.

Scarlet fever is reported to be epidemic in Delray, where from forty to fifty cases have been reported.

Dr. Arthur MacGugan, Kalamazoo, for the last six years on the staff of the State Hospital for the Insane, has resigned, and expects to take a course of special study in Heidelberg.

Embalmers Examined.—By an order of the State Board of Health embalmers in Michigan will be required to pass an examination and receive a license before they are permitted to practice their profession.

Personal.—Dr. George Dock, Ann Arbor, has returned from Europe.——Dr. Gustav Sweet, St. Joseph, will locate in Montana.——Dr. James A. Anderson, Big Beaver, has sold his practice to Dr. W. S. Gass, Rochester.

Dr. Henry D. Thomason, formerly of Albion, but now a major and surgeon U. S. V., on duty in the Philippines, has been made surgeon-in-chief of the Department of Southern Camerines with about 40 posts under his care.

MISSOURI.

Smallpox in malignant form has appeared near Fredericksburg and one patient has died.

Baby Farm Licenses Refused.—The applications for license for five "maternity hospitals," so-called, were refused by the Kansas City Board of Health, August 24.

Dr. Adams' Estate Sued.—University Medical College, Kansas City, has sued the estate of its late dean, Dr. Charles W. Adams, for $36,536.90 fees from students alleged to have been received by him and not turned over to the treasurer.

OHIO.

Removals.—Dr. Oliver T. Sproull, from Bentonville to West Union.——Dr. Melvin M. Acker, from Bryan to Butler, Ind.

Chief Surgeon Louis L. Syman of the Detroit Southern Railway has appointed a full staff of assistants and alternates in his territory.

Dr. Harry P. Findley, for several years assistant at the Massillon State Hospital, has resigned, and Dr. Edward L. Emrich, Wooster, has been appointed his successor.

Madame "Dr." Kelch, Cincinnati, has been arrested, charged with unlawful practice of medicine in Blanchester. She waived examination and was held over to the Court of Common Pleas.

NEW YORK.

Major William P. Kendall, surgeon, U. S. A., is now stationed at Fort Porter, N. Y.

Dr. Alton L. Smiley, Buffalo, has been appointed junior physician at the Manhattan State Hospital at a salary of $900

Board of Health Conference.—A conference of state and provincial boards of health of North America will meet at the Cataract House, Niagara Falls, N. Y., September 13 and 14.

Typhoid fever is more prevalent in Buffalo this year than it was last year, for the same period. From August 1 to 24, 82 cases were reported to the Health Department. Last year for the entire month of August there were 77 reported. The number of deaths reported is but 7 this year, as compared with 13 last August.

Visiting Physicians.—The following physicians have been visiting Buffalo and the Exposition: Dr. Eugene Smith, Detroit; Dr. Lewis S. McMurtry, Louisville; Dr. Charles A. L. Reed, Cincinnati; Dr. N. R. Coleman, Columbus; Dr. George Henry Fox, New York; Dr. Gebhard Ullman, Albany, and Mr. William Whitford, medical stenographer, Chicago.

Buffalo Academy of Medicine.—Regular sessions of the academy for 1901-1902 commenced at the academy rooms, Tuesday, September 3. The medical section, Dr. Julius Ullman presiding, entertained. Dr. John C. Hemmeter, Baltimore, delivered an address on "Intestinal Dystrypsia," and Dr. De Lancey Rochester read a paper on the "Treatment of Pneumonia."

PENNSYLVANIA.

Personal.—Dr. W. W. Dill has decided to locate in Pottstown.——Dr. Ruth Tustin has moved to Bloomsburg from New York City.——Dr. Walter S. Wilson, Lewisburg, has moved to West Chester.——Dr. Arthur C. Wheeler, Erie, has opened an office in Reynoldsville.

Uniontown Hospital.—A permanent organization of the Uniontown Hospital Association was made, August 20. Dr. Thomas N. Eastman was elected vice-president and Dr. Jacob S. Hackney, secretary of the association. The building fund already amounts to $5000.

TEXAS.

Dr. Ramsey D. Potts, Bonham, will locate in Helena, Montana.

State License and Name.—A well-connected criminal bearing the suggestive name of Killum, was arrested for malpractice a short time ago. It developed that he had stolen the license of Dr. Joel A. Blackwell, an esteemed practitioner of Cooper, and had also assumed his name and boldly started out to practice, his sole capital consisting of the license and experience gained while traveling with a horse-doctor.

The following are the resolutions regarding smallpox, adopted at the meeting of the County Judges and Commissioners' Association, held at Dallas, August 8 and 9: "Whereas, smallpox is now and has been widely prevalent over the State during a period of more than three years, thus demonstrating the total insufficiency of our present health laws to furnish the people with the protection against imported pestilential diseases, to which they are justly entitled; therefore be it resolved, that we appeal to His Excellency, the Governor, to recommend to the present session of the Twenty-seventh Legislature to pass an act creating a State Board of Health, with provision for the collection and preservation of the vital statistics of the State; and an equitable distribution of the expense incident to the administration of sanitary measures between the State, the counties and the municipalities thereof, in accordance with the provisions of the Constitution and the recommendation of the late Democratic State Convention in its session at Waco. And be it further resolved, that the secretary of this association be instructed to furnish the Governor with a copy of this resolution as soon as practicable."

GENERAL.

Prof. Paul C. Freer, of the University of Michigan, has been granted leave of absence for one year, with the privilege of more, from the regents. He has been appointed to take charge of one of the Government laboratories in the Philippines.

Tuberculosis in Hawaii.—The records of the Board of Health show an ever-increasing percentage of deaths due to pulmonary tuberculosis. The greatest spread of the disease is among the natives who move from the open air of the country into the closed houses of the towns; they are also lax in their general habits and expectoration.

The Territorial Medical Society of Hawaii met recently and the following resolution was passed: "That the recent attacks made upon Dr. L. E. Cofer, of the U. S. Marine-Hospital Service, for alleged impropriety and discrimination in examining passengers on the *America Maru,* were unfair, uncalled for and not justified by the facts."

Chiropodists Not Required in Army.—The Surgeon-General of the U. S. Army denies the necessity of pedal surgeons in that service, as recently recommended by Col. Philip Reade. The men selected for military service are not of the lame and decrepit variety, and if anything happens to their feet it is more likely to be sufficiently serious to require the attention of the regular surgeon.

Canadian Medical Association.—The most successful meeting of this Association ever held was that in Winnipeg, Manitoba, on August 28 to 31. Much progress was made in the question of Dominion registration, and a Medical Protective Association formed. The next meeting of the Association will take place in Montreal. [illegible] s were electe President, Dr. Francis J. [illegible], general secretary, Dr. George Elliott, Toronto; treasurer, Dr. Henry B. Small, Ottawa.

Scarcity of Physicians in Labrador.—Dr. Grenfell, superintendent of the mission to deep-sea fishermen, now operating in Labrador, publishes an article exposing the medical deficiencies of Labrador. He found people dying of cancer, dropsy, and scurvy, who had never seen a physician. He found no hospital near, no regular steam service to Gaspé or Quebec, and no means by which the people could procure medical or surgical treatment. He urges the Dominion government to take prompt steps to remedy these conditions.

Inefficiency of the Caldas Serum.—Dr. Caldas is returning to Brazil, since his experiments with the alleged yellow fever remedy have resulted in failure. He and Dr. Bellinzaghi came to this country some weeks ago and endeavored to enlist the co-operation of the Medical Department at Washington, but without success. They then went to Havana and Governor-General Wood was induced to appoint a commission to investigate the claims of the Brazilians. This board consisted of Drs. Gorgas, Finlay, Guiteras and Agramonte. It has finally decided that under no condition should further experiments of the kind be made. A full report will soon be made and filed with the Governor-General.

FOREIGN.

Prize for Van Gehuchten.—The Belgian quinquennial prize for medical research, amounting to $1000, has been awarded to Professor Van Gehuchten for his studies on the brain and spinal cord.

Heidelberg's New Restrictions on Foreign Medical Students.—The lay press announces that the authorities at Heidelberg have decreed that hereafter no foreign students shall be admitted to the medical course who have not passed an examination fully equivalent to the "Abiturienten examination" exacted in Germany.

English Commission on Tuberculosis.—King Edward has appointed the commission to investigate the transmissibility of animal and human tuberculosis. It is to consist of Sir Michael Foster, secretary of the Royal Society; Dr. Germain Sims Woodhead, the pathologist; Prof. J. McFadyean; Prof. W. Boyce, and Dr. Harris Cox Martin.

The French Degree of Colonial Medicine.—The French universities at Bordeaux and Marseilles are instituting a course of colonial medicine, entitling the graduates to the degree of Doctor of Colonial Medicine. The hospitals of Marseilles afford unusual opportunities for studying the diseases prevalent in the French colonies, mostly in the tropics.

Deaths Abroad.—Dr. Holland, gynecologist at Berlin, in his thirty-sixth year. His death was determined by sepsis from a professional injury. Other deaths reported are those of Dr. Fontorbe, professor of surgery at Rochefort; Dr. Salitschew, professor of surgery at Tomsk; Le Roy de Méricourt, of Paris, born 1825, founder and editor of the *Archives de la Méd. Navale.*

Success of the Danyz Bacillus for Exterminating Rats.—The *Deu. Med. Woch.* for August 22 contains a communication from Moscow describing the complete success of the experiments with the Danyz bacillus. It proved very pathogenic for rats, and by mixing the cultures with a concentrated alkaline solution, the acidity of the gastric juice was neutralized, and the virulence of the bacilli maintained unimpaired by passage through the animals.

Alwin Von Coler, Surgeon-General of the German Army, whose death was noted in the last issue of The Journal, was born March 15, 1831, at Gröningen, of an old patrician family of Hartz origin. After four years (1852-56) in the Military Academy of Berlin, he entered the Dragoon-Guards regiment as acting assistant surgeon, becoming assistant surgeon in 1857 and surgeon in 1863. Owing to his efficiency in the campaign of 1864-66 he was in 1867 promoted to the Medical Staff of the Prussian army, and, in 1868, on the establishment of the Medical Department in the war office was appointed decernent therein. Excepting 1870-71 during which years he was Division Surgeon of the First Active Division, his service in the war department has been continuous. In 1874 he became surgeon-general, in 1885 chief of the Medical Department, and in 1889, surgeon general of the army, chief of the sanitary corps and of the Medical Department of the war office and director of the Kaiser Wilhelm Academy for Military Medical Science. In 1889 he was appointed chief privy medical counsellor, in 1891 lieutenant-general, and in 1892 honorary professor in the University of Berlin. Under Von Coler's administration the organization of the Medical Department of the army for war or peace was placed on a new foundation and the sanitary corps was raised to a high grade of efficiency. It was also Von Coler's constant aim to establish close union of the military with the civil medical profession.

Miscellany.

Vaccine.—Not alone in Cleveland but all over the country are heard more or less positively expressed suspicions of the purity of much of the vaccine virus at present on the market. It is probable, we fear, that there is some fire beneath all this smoke, and yet certain makers of vaccine are now ideally careful and clean in the preparation of the virus. As matters stand, however, the innocent are likely to suffer with the guilty, unless there is designed some effective method of guaranteeing the purity of the virus. If it were possible, it would appear that the manufacture of vaccine should be placed under Federal inspection. The Department of Agriculture, by adding slightly to its very capable scientific staff, could very readily and authoritatively assume this work. Perhaps this reform, which should be demanded by the honest manufacturers for their own protection as well as by the medical profession, could best be compassed by placing a very small revenue tax on vaccine, just sufficient to raise money for the expense of the inspection, and by providing minimum standards of chemic and bacteriologic purity. This is a very important matter which should be dealt with thoroughly by the effectively reorganized American Medical Association. The matter should not be permitted to rest, but should be persistently agitated. No doubt some better method can be devised, and the only point on which the Journal insists is that a means must be found to ensure the purity of vaccine.—*Cleveland Journal of Medicine,* August.

General Hospital in Samara, Russia.—The General Hospital at Samara is located in a handsome park near the western limits of the city, and consists of a number of wooden buildings, in barrack style. Each building does service for seventeen years, when it is removed and replaced by a new one. At present the hospital contains 400 patients. These patients are admitted from all parts of the Samara province and pay 20 kopeks a day. If the applicant is destitute, as is often the case, the district from which he comes pays this small charge for him. We spent half a day in the surgical section, in charge of Dr. Johannes Dsirne, a surgeon of more than a local reputation. We had the pleasure of witnessing two operations for stone in the bladder. Stone in the bladder is quite common in this section of the country, as this surgeon performs annually on an average 100 operations. Although the operating-room lacks many of the modern conveniences, the results obtained would compare well with those in our best equipped institutions, something we must attribute to the pedantic cleanliness of the operator and his assistants. The anesthetic, chloroform, was administered by a female feldscheer or barber surgeon, and two other women of the same grade of medical education rendered assistance. The chief assistant was a recent graduate in medicine. These barber surgeons, male and female, are expected to assist licensed physicians, but are not permitted to operate or prescribe except in cases in which the services of a regular graduate in medicine can not be secured. These barber surgeons must study their profession for four years, and the women are required to take an additional course in gynecology and obstetrics. Both patients were puny boys from the steppes of western Russia. In one case the high operation was performed; in the other the stone was removed by median perineal section after crushing. It is a fact worthy of note that according to the experience of Dr. Dsirne the peasants are almost immune against shock, he in his large experience having only observed one case. Dr. Dsirne invariably sutures the vesical wound in performing the high operation, using two rows of fine silk sutures, excluding carefully the mucous membrane. In most cases uncomplicated by cystitis he has seen the wound heal by primary intention. If cystitis is present he drains. Dr. Dsirne is a careful, conscientious, and dexterous operator. I am glad to know that he will visit the medical institutions of Chicago some time next summer.—Dr. N. Senn, in *Chicago Tribune,* Sept. 1.

Reorganization of the American Medical Profession.—The plan of the Committee for the federation and interdependence of the National, State and County societies is an excellent one. Membership in the county society becomes a prerequisite to membership in the other organizations. The county organization thus becomes an unit of the state association, and the state of the National body. Each is thereby strengthened and made more powerful, each becomes more cohesive and each develops into an effective, offensive or defensive organization which will command respect and consideration because it represents an organized power which is able to reward or punish, both its friends and its enemies. The medical profession in America is large in numbers, but it lacks stability and cohesiveness when called upon to protect its interests against agencies that are detrimental to its welfare. In this it, in no small manner, is similar to that Asiatic nation, the so-called celestial kingdom, which is great in numbers but whose slight stability and cohesive power renders it an easy victim to its enemies. Reorganization of the medical profession in America is a necessity. This must begin in the county society which is to form the basic part upon which the entire fabric of an organized profession must rest. Upon these is to be built the state organization, and from the State societies must come the chosen few who are to wear the senatorial togas in the parliamentary body of the American Medical Association, the body that is to formulate the policy of the profession on matters of vital interests, the body that is to aid destiny to shape our ends to a satisfactory conclusion, rough hewn though they be, the recommended House of Delegates of the American Medical Association. As recommended by the Committee, regional, tri-state and district societies, save in a few instances, should be abolished. These, as at present constituted, serve but a slight purpose for good, while on the other hand they weaken and detract from the county and state societies that as federated units are essential to the integrity of the National Association. They are parasitic growths on the medical body politic which sap the life strength of the National organization, and as such should be lopped off and allowed to perish. Let their friends and promoters devote their energies to the upbuilding of their respective state and county societies where their efforts will add to the strength of the profession as a body, and where they will hasten and not hinder the consummation of professional unity. In the trinity of National, state and county organizations, a federated union, in which each is developed to its greatest possibilities, will the profession find a power, that, like faith, can move mountains.—*Courier of Medicine*, July.

Book Notices.

THE PRESENT POSITION OF THE TREATMENT OF SIMPLE FRACTURES OF THE LIMBS. An Address Delivered in Opening a Discussion at the Meeting of the British Medical Association held at Ipswich, August, 1900. By William H. Bennett, F.R.C.S., Senior Surgeon to St. George's Hospital. To which is Appended a Summary of the Opinions and Practice of about 300 Surgeons. Reprinted, after revision, from the British Medical Journal, Oct. 7, 1900. Cloth. Pp. 41. Price, $0.80. New York and Bombay: Longmans, Green & Co. 1900.

This little volume is an address delivered before the British Medical Association in August, 1900, and reprinted from the *British Medical Journal* of Oct. 7, 1900.

In it the author briefly states the general plan of treating the ordinary fractures as employed by himself, and particularly emphasizes the advantages of early movement in the treatment of fractures and the employment of splints which can be readily taken off, so that the limb and fracture may easily be rendered accessible.

In an appendix are the answers from about three hundred surgeons in England to certain questions concerning the treatment of fractures, which were submitted to them by the author. As was to be expected, a larger percentage of those surgeons living in London and in large centers adopt the more advanced methods, such as the use of massage, passive movements and operative procedures, than of those living in the provinces. The general status of the treatment of fractures by English surgeons is well illustrated in the little volume.

ON THE USE OF MASSAGE AND EARLY PASSIVE MOVEMENTS IN RECENT FRACTURES and other Common Surgical Injuries and the Treatment of Internal Derangement of the Knee-Joint. Three Clinical Lectures Delivered at St. George's Hospital. By William H. Bennett, F.R.C.S., Senior Surgeon to the St. George's Hospital. Reprinted, after revision, from The Lancet. With 12 Illustrations. Cloth. Pp. 97. Price, $1.40. New York and Bombay: Longmans, Green & Co. 1900.

The author, in his note, explains that these three lectures have been already published in *The Lancet*, the only difference being "a few verbal alterations," and the addition of three illustrations. The author's strong plea for the use of massage and early passive movements in the treatment of recent fractures is very convincing, and the explanations very rational. One criticism, however, might be offered with regard to fractures of the neck of the femur. He does not insist, as some modern surgeons do, that union is nearly always possible, but dismisses the subject by simply advising the use of massage and passive movement without any attempt at fixation. In all other fractures he is very careful to maintain fixation at the region of fracture with the hand while making use of passive motion, or as he terms it, internal massage. His advocacy of the use of the above procedures in the treatment of dislocations, sprains, etc., leaves nothing to be desired. The chapter on internal derangements of the knee-joint deals with the subject in a very clear and concise manner.

A TEXT-BOOK OF OPHTHALMOLOGY. By John W. Wright, A.M., M.D., Professor of Ophthalmology and Clinical Ophthalmology in the Ohio Medical University. Second Edition, Thoroughly Revised. With 117 Illustrations. Cloth. Pp. 378. Price, $3.00. Philadelphia: P. Blakiston's Son & Co. 1900.

In this work the student and practicing physician learn the why and wherefore of anomalies and methods of treatment and procedure. It contains, among others, chapters on retinoscopy, ophthalmoscopy, injuries, color-blindness, elementary optics, and refraction. The different operations for extraction of cataract are carefully considered, but we miss the orthoptic exercises for muscular insufficiency. An important feature of the treatise is an ophthalmologic glossary; this is not only a convenient but also a necessary adjunct, as is evident from the inaccurate pronunciation of many of our oculists, for instance of the word "chalazion," and even "pterygium."

TRANSACTIONS OF THE INDIANA STATE MEDICAL SOCIETY, Fifty-Second Annual Session held in South Bend, May, 1901. Logansport, Ind.; Wilson, Humphrey & Co. 1901.

The present volume, according to the preface, is the largest every published by the Society. It is certainly a large volume, but the Society is to be congratulated especially that the quality of its contents is so excellent. There are 41 original papers and 2 symposiums, besides several scientific reports; all of these are up to, and many above, the average. The paid membership is 1624, which is but little more than a third of the regular physicians of the state, not a good showing when it is remembered that membership in county societies carries with it membership in the state society. "Efforts to form new societies," says the secretary in his report, "have not been successful during the past year." It would be interesting to know what these efforts were and how they could be made more effective. Two-thirds of the members of the regular profession in a state who do not belong to any society is not a very satisfactory condition. And yet how many states are doing better?

ORTHOPEDIC SURGERY. A HANDBOOK. By Charles Bell Keetley, F.R.C.S., Surgeon to the West London Hospital. Cloth. Pp. 539. Price, $5.50 net. London: Smith, Elder & Co. 1900.

The author says he planned this work nearly twenty years ago, and that it is the result of twenty-two years devoted to thought and labor in the study of deformities and in practicing their treatment. He also says he has "felt a desire to remove some of the dust in which mistaken ideas of what constituted proof had gradually been hiding simple facts about the pathology and treatment of deformities."

He does this by attributing nearly all deformities involving the bones to rickets, and speaks of syphilitic rickets, scurvy rickets, common rickets, rickets of adolescence, etc., practically disregarding other factors, except infantile paralysis. This view is too extreme. There is also a tendency to dodge important points by asking questions, the answers to which are often not forthcoming. For instance, he denies the influence of muscular action in forming the arch of the foot by asking the question: "What muscles arch the Roman nose?" In the etiology of flat foot no mention is made of the effect of trauma in breaking down the arch.

On one page he says that after tenotomy the foot should be immediately placed in the best attainable position, and on the next that "complete correction should only be aimed at by gradual extension, commencing a fortnight after the tenotomy and prolonged over several weeks."

The fact that the muscle sheath, fasciæ of the neck and other tissues besides the sterno-cleido-mastoid muscle are involved in wry-neck is not sufficiently recognized, neither under the pathology nor when considering the treatment. The chapter on scoliosis is very good; in fact the spinal troubles are better handled than are those of the extremities. While one may be disappointed with the pathology as laid down in the work, there are many valuable points to be learned under Treatment, and it is here especially that the author shows his great practical knowledge and ability.

Married.

Stafford P. Jones, M.D., to Miss Mary Wilmarth, both of Marinette, Wis., August 22.

M. R. Beaudoin-Bennett, M.D., Jackson, Mich., to Miss Jean Martin at Trinity Church, Hewletts, L. I., August 21.

Herbert Emmons Stockwell, M.D., Stockbridge, Mass., to Miss Blanche Newton Cook, Brookline, Mass., September 4.

Charles Harrison Frazier, M.D., Philadelphia, to Miss Mary Spring Gardner at the chapel of St. Marys-by-the-Sea, North East Harbor, Maine, August 24.

Deaths and Obituaries.

Thomas Masters Markoe, M.D., College of Physicians and Surgeons, New York City, 1841, died, August 28, at his summer home at Easthampton, L. I. Dr. Markoe was a native of Philadelphia and graduated from Princeton in 1836. After obtaining his medical degree he was made professor of anatomy in Castleton Medical College, Castleton, Vt., and from 1852 to 1854 filled the chair of pathological anatomy in New York University. From 1860 to 1870 he was adjunct professor of surgery in the New York University, and from 1870 to 1879 he filled the chair of surgery in the same institution. In 1879 he accepted the chair of principles of surgery in the College of Physicians and Surgeons, and this position he held until his retirement when he was made professor emeritus. He was consulting surgeon to the New York, Roosevelt, Mt. Sinai, Woman's and St. Mary's hospitals; consulting physician to the Nursery and Children's Hospital, and a member of the New York Academy of Medicine, New York County Medical Society, New York Pathological Society, New York Medical and Surgical Society and the Society for the Relief of Widows and Orphans of Medical Men. He was a frequent contributor to surgical and orthopedic literature.

Alfred Sanford Dana, M.D., College of Physicians and Surgeons, New York City, 1874, a prominent physician of Westchester county, residing at Yonkers, N. Y., was killed by an express train on the Harlem branch of the New York Central railroad at the Bronxville crossing, August 22, aged 50. He was driving across the tracks when an express train rounded the curve and the coachman was unable to get the team over in time.

Homer C. Markham, M.D., New York University, 1859, one of the pioneer settlers and practitioners of Kilbourn, Wis., who served throughout the Civil war as surgeon of the 19th Wisconsin, and then moved to Buchanan County, Iowa, died suddenly at his home in Independence, from Bright's disease, August 18, aged 63.

James B. Massie, M.D., St. Joseph Hospital Medical College, St. Joseph, Mo., 1887, health officer of Houston, Texas, a member of the State Board of Medical Examiners and a successful physician of Houston, died at Fayetteville, Ark., from Bright's disease, after a prolonged illness, August 24, aged 45.

William W. S. Butler, M.D., University of Virginia, Richmond, 1852, died at Harrisonburg, Va., August 18, at an advanced age. He was formerly connected with the U. S. Internal Revenue Service. For several years he resided in Roanoke, Va.

H. P. Mathewson, M.D., formerly a well-known physician of Omaha, Neb., and from 1874 to 1879 superintendent of the State Hospital for the Insane at Lincoln, died suddenly at the residence of his son, in Los Angeles, Cal., August 19, aged 70.

Columbus P. Brent, M.D., Miami Medical College, Cincinnati, 1854, who has practiced medicine in Cincinnati for more than thirty years, died at his home in that city, August 21. He was a member of the American Medical Association.

Joseph Moffat, M.D., University of Michigan, Ann Arbor, 1862, of Washingtonville, N. Y., a member of the Orange County Medical Society and the New York State Medical Society, died at his home, August 16, aged 68.

Abram R. Van Dusen, M.D., Albany Medical College, 1841, one of the oldest and most successful physicians of Columbia County, N. Y., died suddenly at his home in Humphreyville, August 21, aged 81.

James M. Howard, Jr., M.D., Jefferson Medical College, Philadelphia, was dragged to death in a runaway accident at Fairmont, W. Va., August 19. He was a resident of Masontown, Pa.

Robert M. Murphy, M.D., Bellevue Hospital Medical College, New York, 1880, died at his home in Kingston, N. Y., August 22, from apoplexy, aged 52.

Frank B. Smith, M.D., Rush Medical College, Chicago, 1880, died at his home in Springfield, Ill., after a prolonged illness, aged 42.

Russell C. Wyman, M.D., College of Physicians and Surgeons, Keokuk, Iowa, 1878, died at his home in Maitland, Mo., August 14.

Societies.

COMING MEETINGS.

American Academy of Railway Surgeons, Chicago, Sept. 12-13, 1901.

Mississippi Valley Medical Association, Put-in-Bay, Sept. 12-14, 1901.

Conference of State and Provincial Boards of Health of North America, Niagara Falls, Sept. 13-14, 1901.

American Public Health Association, Buffalo, Sept. 16-20, 1901.

American Association of Obstetricians and Gynecologists, Cleveland, Ohio, Sept. 17-19, 1901.

Medical Society of the Missouri Valley, St. Joseph, Mo., Sept. 19, 1901.

Nevada State Medical Society, Reno, Sept. 21, 1901.

Medical Society of the State of Pennsylvania, Philadelphia, Sept. 24-26, 1901.

American Electro-Therapeutic Association, Buffalo, Sept. 24-26, 1901.

Oregon State Medical Society, Portland, Sept. 25-27, 1901.

Utah State Medical Society, Provo City, Oct. 1-2, 1901.

Idaho State Medical Society, Pocatello, Oct. 3-4, 1901.

Tri-State Medical Society of Alabama, Georgia and Tennessee, Nashville, Tenn., Oct. 8-10, 1901.

Wyoming State Medical Society, Evanston, Oct. 8-9, 1901.

Vermont State Medical Society, Montpelier, Oct. 10-11, 1901.

New York State Medical Association, New York City, Oct. 21-24, 1901.

Tri-State Medical Society of Alabama, Georgia and Tennessee.—The thirteenth annual meeting of this Society will be held at Nashville, October 8, 9 and 10. The secretary is Dr. Frank Trester Smith, Chattanooga, Tenn.

Piscataquis County (Maine) Medical Association.—The annual meeting of this Society was held in Dover, August 15. The following officers were elected: Dr. Ralph H. Marsh, Guilford, president; Dr. William Buck, Foxcroft, vice-president; Dr. Charles W. Ray, Sangerville, secretary, and Dr. Alvin H. Stanhope, Dover, treasurer.

Trenton (N. J.) Medical Library Association.—At a meeting of physicians held in Trenton, August 22, it was decided to form a permanent organization for the purpose of establishing a medical library in connection with the Free Public Library, and Dr. Horace G. Norton was made president; Dr. F. V. Cantwell, vice-president, and Dr. George N. J. Sommer, secretary and treasurer.

Franklin District (Mass.) Medical Society.—This old Society, now in its 51st year, has just issued a booklet giving the names of the officers and members, and the programs of the meetings of the past year. There are 32 members, the oldest of whom is Dr. E. A. Deane, of Montague, who became a member in 1862, and is called the "dean" of the Society. The first officers of this society were Stephen West Williams, Deerfield, president; the first secretary and treasurer was James Deane, of Greenfield. The first members to be admitted were Stephen J. W. Talbot of Shelburne Falls and Charles L. Knowlton of Ashfield on June 3, 1850.

ELEVENTH FRENCH CONGRESS OF ALIENISTS AND NEUROLOGISTS.

Held at Limoges, August 1.

President's Address.

In his presidential address Gilbert-Ballet remarked that it is dangerous and presumptuous to fasten a stigma on the offspring in case of certain accidental affections of the nervous system, such as ataxia, general paralysis or hemiplegia from a circumscribed lesion. He concluded by emphasizing the tendency of the new century to regard the pathology of the nervous system, and especially mental pathology, from the standpoint of society at large. The study of the psychology of a crowd will lead to a knowledge of its pathology. The crowd has its own individuality, its special emotions, reactions, obsessions and morbid impulses, the same as the individual.

Joffroy reported two cases of general paralysis in which the temperature suddenly began to fall and the patients died in three to five days with a temperature of 25 and 27 C. (77 and 81 F.). One patient was in coma at the time, but the other had no symptoms of coma, convulsions nor diarrhea.

INHERITED DEGENERACY.

Bourneville announced that hereditary syphilis has been noted in only 1 per cent. of the idiot, imbecile or epileptic children in his service, but alcoholism was evident in the antecedents of more than 40 per cent. He stated that in 87 families in which one or both parents were engaged in handling white lead, mercury, phosphorus, copper, etc., 52 per cent. of the children died, and 21 per cent. of the surviving 200 children were idiots or epileptics. This shows that about 73 per cent. of the children of parents following an unhealthy trade are seriously or fatally affected. He also mentioned several instances of transient purpura occurring after epileptic seizures.

Practical Application of Mirror-Writing.

In a communication on this subject Meige called attention to the fact that mirror-writing is the spontaneous effort of the left hand to write, in persons writing normally and fluently with the right hand. A similar phenomenon is observed with other movements which the right hand has learned to perform. The left hand spontaneously reflects, in reversed order, the movement or action of the right hand. What the cortical center for the right hand has learned, is reflected on the center for the left hand, which is thus unconsciously educated to a certain extent. When a center presides over a movement, the symmetrical center has a tendency to command the same movement, but in reversed order. Consequently in re-educating a member, the task will be much facilitated by having the symmetrical member execute and repeat the same movement.

Juvenile General Paralysis.

Régis observed that a hundred cases of general paralysis under 20 could be collected in literature. Usually hereditary syphilis can be incriminated, but Westphal has reported a case of general paralysis in a girl of 17, traceable to syphilis acquired at 7. Ballet has observed several instances in which the paralysis appeared three to five years after the syphilitic infection.

Evolution of Syphilis.

Brissaud remarked that his experience is confirming Fournier's assertion, that syphilis is undergoing a process of evolution in our day, in virtue of which the manifestations during the secondary period are becoming milder and milder, while those of the tertiary period are becoming more numerous and more formidable. Régis proclaimed his conviction that tuberculosis or any other infection may be the etiologic factor in general paralysis—and not necessarily always syphilis. The first address was on

Acute Delirium.

Carrier's statements were generally approved that acute delirium is a syndrome of a toxi-infectious nature, depending on various infections and intoxications, and is not a morbid entity. The nervous elements are altered by the pathogenic agent and hence allow the development of secondary autointoxications, which are the cause of its gravity. Crocq, of Brussels, aroused much discussion by his address on the

Physiology and Pathology of the Muscle Tonus, Reflexes and Contractures.

The routes of muscle tonus in the lower vertebrates, he said, are the shortest possible. The higher in the animal scale, the more the longer routes take the place of the shorter, until in man, the long routes for the tonus of the voluntary muscles are the normal and the only ones. The sphincters still retain the short routes. Excitation of a voluntary muscle inhibits the tonus of its antagonist, and the reverse is also true, i. e., that with diminished tonus in one muscle the tonicity of its antagonist is increased. Crocq adds three new laws to these: 1. Complete destruction of the central or peripheral motor neurons or of their cylinder-axis prolongations entails the atony of the corresponding muscles with complete and definite laxness. 2. Their partial destruction entails diminished tonicity; and 3, lesions of the tissues surrounding the nerve cells or their prolongations may hamper the nerve in its functional activity by mechanical compression from the injured tissues, and induce a functional erethism manifested in an exaggeration of the muscle tonus. The reflexes were formerly all attributed to the spinal cord, but we know now that the reflex movements are moderated by still higher centers in man at least. The long routes are indispensable to the production of the reflexes in man as is shown by their complete disappearance after section of the cervico-dorsal cord. On the other hand, destructive processes in the brain abolish or attenuate the cutaneous while they exaggerate the tendon reflexes. Destruction of the motor cortex induces exaggeration of the tendon reflexes in all animals and this is also induced in man and higher animals by a destructive process in the cerebellum. Consequently, it seems evident that in the human adult the cutaneous reflexes have their centers in the cerebral cortex and the tendon reflexes in the mesocephalon. The short routes become atrophied as the child grows to maturity, but they always suffice for very rapid defensive actions induced by a violent stimulus. Weaker impressions (cutaneous reflexes) traverse by preference the long routes. The tendon reflexes are exaggerated when the cerebral or cerebellar inhibiting action is weakened or abolished, either from irritation of the pyramidal tract or the basilar cells, as in organic hemiplegia and pareto-spasmodic conditions, or from irritation of the peripheral neuron as in case of sclerosis or compression of the spinal cord. Exaggeration of the cutaneous reflexes is due to individual peculiarities and various intoxications, and not to organic lesions of the nerve routes. Diminution or abolition of both the tendon and cutaneous reflexes follows the alteration or functional disturbance of the cells or fibers engaged in their production. The relations between the condition of the sensibility and that of the cutaneous reflexes are very close. The parallelism is constant in organic affections. The antagonism between the tendon and cutaneous reflexes frequently noted in organic affections and even in supposed health, is another argument in favor of their different localization. The toe reflex should not be considered a true cutaneous reflex, as it may persist after the cord has been severed. In lesions of the tissues surrounding the cylinder-axes of the pyramidal tracts, the irritation of the fibers induces erethism of the basilar neurons presiding over the tendon reflexes, and exhaustion of the cortical neurons involved in the production of the cutaneous reflexes. Hence exaggeration of the former and diminution of the latter. This also occurs after repeated stimulation of the reflexes; the cutaneous reflexes become weaker and weaker while the tendon reflexes become more and more exaggerated. Contracture is an exaggeration of the muscle tonus and may be due to inhibition of the antagonist muscle, or to a lesion of the tissues surrounding the central or peripheral motor neurons. There is no essential difference between the contracture in convulsions and that of hemiplegia, but in the pseudo-contracture of hemiplegia, with retraction of the tendons, there is evidently some alteration of the peripheral motor neuron with interference with its trophic function. Muscular hypertonicity does not necessarily coincide with exaggerated tendon reflexes—another argument in favor of their anatomic independence. The amount of contracture is usually proportional to the vigor of the muscle. Although some disturbance in the central or peripheral motor neurons is the principal, if not the only cause of contracture, yet there is considerable difference between the contracture due to each.

Therapeutics.

[It is the aim of this department to aid the general practitioner by giving practical prescriptions and, in brief, methods of treatment for the diseases seen especially in every-day practice. Proper inquiries concerning general formulae and outlines of treatment will be answered in these columns.]

Removal of Lanugo and Hairs.

A subscriber asks for a safe method (not electrolysis) of permanently removing superfluous hair, especially lanugo of the upper lip of girls.

There is no method of permanently removing hairs other than by electrolysis. This should not be attempted in such cases as mentioned above. A growth of coarse hair will recur even after electrolysis.

Treatment of Pertussis.

Just at this time of year pertussis seems to be very prevalent in some localities. This time in the year is certainly favorable to the prognosis of the disease. The little patients can be kept in the open air, and not housed in close rooms, which lessens the number of paroxysmal attacks of coughing as well as the severity of the attacks. The medicinal treatment is divided into the antiseptic, the anti-catarrhal and the sedative treatment.

Yeo is convinced that carbolic acid inhalations is of great value in the antiseptic treatment of this disease. He places the child in a small room containing an open fire-place; a large iron spoon should be made hot from time to time and carbolic acid vaporized by putting a teaspoonful or two into the heated spoon. The atmosphere should be so strongly impregnated with this vapor, according to Yeo, as to make the atmosphere unpleasant to others. These fumes should be kept up night and day. As a spray for direct inhalation he recommends the following:

℞.	Acidi carbol.	ʒi	4	
	Glycerini	ʒi	4	
	Sodii bicarb.	gr. x		66
	Aq. destil	℥i	32	

M. Sig.: Use as a spray in front of the mouth of the infant constantly, so that he is compelled to inhale it.

The urine should be under constant observation during above treatment and if any discoloration occurs the treatment should be suspended for twenty-four hours.

FOR THE PAROXYSMS.

The following combination is recommended to lessen the severity of the paroxysm and to render the expectoration less tenacious:

℞.	Sodii benzoatis	gr. lxxii	5	
	Sodii bicarb.	gr. xlviii	3	20
	Ammonii chloridi	gr. xxiv	1	66
	Aquæ chloroformi	℥i	32	
	Aquæ anisi, q. s. ad	℥iii	96	

M. ft. mistura. Sig.: One to four teaspoonfuls according to the age of the child, in a little hot milk, every four hours.

Bamberger recommends the following the moment the attack comes on.

℞.	Sodii bicarb.		
	Sacchari, āā	ʒii	8

M. Sig.: Dissolve a small amount of the powder in hot water and give to the patient as the paroxysm of coughing comes on.

Dujordin-Beaumetz recommends the triple bromids for relief of the paroxysm as follows:

℞.	Ammon. brom.		
	Sodii brom.		
	Potassii brom. āā	ʒss	2
	Syr. chloralis	℥i	32
	Aquæ, q. s. ad	℥iv	128

M. Sig.: One teaspoonful or more according to age, in milk night and morning.

Roth recommends the following:

℞.	Acidi carbol.	gr. xv	1	
	Spts. vini rectif.	m. xv	1	
	Tinct. iodi	m. x		66
	Tinct. belladonnæ	m. xxx	2	
	Syr. papaveris	ʒiiss	10	
	Aq. menth. pip. q. s. ad	℥ii	64	

M. Sig.: One teaspoonful every two hours for a child between one and two years of age; half the quantity diluted with water for infants under one year of age.

HEROIN IN WHOOPING COUGH.

Dr. H. H. Haralson, of Vicksburg, Miss., recommends the administration of heroin, beginning early in the attack and continuing it through the catarrhal and paroxysmal stage. During the last stage he recommends tonics, good nourishment and proper hygienic surroundings. The following combination is employed by him:

R.	Heroin hydrochlor.	gr. ¼ to ½		015-03
	Tinct. belladonnæ	ʒi	4	
	Spts. frumenti	℥i	32	
	Syrupi simplicis, q. s. ad	℥iv	128	

M. Sig.: One teaspoonful every five or six hours.

Dr. Haralson seems to be very enthusiastic over his success in ameliorating the paroxysm and lengthening the time between the paroxysms as well as cutting short the duration of the disease.

TREATMENT OF WHOOPING COUGH BY IRRIGATION OF THE NARES.

W. Lattey, according to *British Medical Journal*, states that the irrigation of the nares in pertussis should be more frequently employed. The child should be rolled up in a shawl with the arms confined, and placed face downward across the nurse's lap. Tepid water should first be used with a soft india rubber tube attached to the syringe. This should be followed by some antiseptic solution. The same treatment should be carried out with both sides.

Treatment of Erysipelas.

J. Hays, in *Jour. de Méd. de Paris*, recommends the following as a lotion in the treatment of erysipelas:

℞.	Acidi carbol.		
	Tinct. iodi		
	Alcoholis, āā	ʒss	2
	Olei terebinthinæ	ʒi	4
	Glycerini	ʒiss	6

M. Sig.: For external application.

Every two hours the erysipelatous part may be painted with this liquid as well as a small zone of the surrounding healthy tissues, and the whole covered with aseptic gauze.

A Sedative in Tubercular Meningitis.

The *New York Med. Jour.* recommends the following, as advised by Malba, to combat the agitation, the cries and convulsions in tubercular meningitis.

℞.	Strontii bromidi	gr. xv	1	
	Chloralis hydratis	gr. viiss		5
	Syr. Valerianæ	ʒv	20	
	Syr. menthæ	℥ii	64	

M. Sig.: One teaspoonful every half hour until quiet is obtained.

Intestinal Tuberculosis in Infants.

The following is noted in *New York Med. Jour.*:

R.	Argenti nitratis	gr. ii		12
	Pulv. amyli			
	Pulv. altheæ, āā	gr. v		33

M. ft. pil. No. xv. Sig.: One pill to be taken daily for three consecutive days after the administration of a light saline aperient.

If the diarrhea does not stop, the dose should be raised to two or even three pills daily during two consecutive days. This treatment is suitable for children ranging in age from 5 to 10 years.

For young infants the following is recommended:

R.	Argenti nitratis	gr. 1/6		01
	Syrupi idei	℥iss	48	
	Aq. destil. q. s. ad	℥iii	96	

M. Sig.: From a dessertspoonful to the entire draught according to age once or twice daily.

Absorption of Drugs by the Bladder.

Barbiana, according to the *Ther. Gaz.*, has found by experimental research that dilute solutions of various drugs, with the exception of iodin, are never absorbed by the bladder at first irrigation, but that if consecutive irrigations are made there is fairly active absorption. This he attributes to certain functional disturbances of the epithelium incident to the mechanical action of the lavage upon the vesical walls, since such absorption may take place without further alteration of this epithelium. He believes that the complete retention is in itself sufficient to produce such changes in the vesicular wall as are calculated to encourage absorption.

Salivation Following Ether Narcosis.

The salivation in ether anesthesia is usually excessive and very often is a factor in the cause of bronchitis and pneumonia following its employment.

Dr. W. Reinhard, as stated in *Merck's Archives*, recommends the following as a preventive:

R.	Atropinæ sulphatis	gr. 1/6		01
	Morphinæ hydrochloratis	gr. iii		20
	Aq. destil. q. s. ad	ʒiiss	10	

M. Sig.: Inject from eight to sixteen drops, according to the condition of the patient.

Treatment of Umbilical Hernia.

The *Med. Record* makes a note of the treatment of umbilical hernia according to the method of J. C. Hubbard, by means of adhesive plaster strapping. He states that the younger the child the earlier the cure is to be expected. The failure of cure and the danger of recurrence are slight. The author reports 28 cures out of 60 cases.

Pelletierin Tannate in Tapeworm.

The following combination containing pelletierin tannate has been used with almost uniform success in treatment of tapeworm, but it disturbs the stomachs of some patients:

R.	Oleores. aspidii	ʒiv	16
	Olei terebinthinæ	ʒii	8
	Pelletierin tannatis	ʒi	4
	Spts. chloroformi	ʒi	4

M. Sig.: Shake well. One teaspoonful in the morning on an empty stomach followed in about two hours by a saline cathartic.

Treatment of Tabes Dorsalis.

Collins, in *New York Med. Rec.*, summarizes the treatment as follows: 1. The determination as to whether antispecific treatment shall be employed. 2. The utilization of electricity, hydrotherapy, massage and counterirritation. 3. The education of the ataxic members, the rehabilitation of purposeful movements. 4. The relief of subjective symptoms, such as pain, crises, dereliction of bladder function, ocular paralyses, amaurosis and trophic disturbances. 5. Adopt a plan of treatment and carry it through.

It might be added in addition to Dr. Collins' statements that the value of antispecific treatment is questionable unless the symptoms of tabes come on comparatively early after the infection. In other words, if tabetic symptoms do not make their appearance earlier than five years or if the syphilis in its active stage has received strong treatment the employment of mercury and the iodids is usually productive of harm. On the other hand, too much stress can not be placed upon the value of exercise to re-establish co-ordination after Fraenkel's methods, while inactivity and disuse greatly decrease muscular control as well as discourage the patient.

Medicolegal.

Basis of Recovery for Services as Health Officer.—The Court of Appeals of Kentucky holds, in Henderson County vs. Dixon, that where an action is brought for the recovery of compensation for services alleged to have been rendered as health officer, and the appointment of the claimant is traversed by the answer to his petition, it is incumbent upon him to prove the organization of the county board of health, and also his appointment to the position claimed by him. It is further of the opinion, too, that such appointment should be proven by the records of the county board, or some reason given for the introduction of oral testimony. Again, when the appointment is denied, it holds that it is a question of fact for the jury to find that the claimant was duly appointed, before it can, in any event, allow him any compensation. Then, complaint was made in this case of the admission of testimony, in this: that the witnesses, in fixing a reasonable compensation, were permitted to base their opinion as to the value of services upon the standing of the claimant as a physician. But the court holds that it was competent to show that he was a physician of good standing and of long practice, and that the jury might take such facts into consideration in determining the value of his services, though the criterion of recovery, if entitled to recover at all, was reasonable compensation.

License a "Right"—Validity of Act as to Revoking.—The license to practice medicine which one receives, the Court of Appeals of Kentucky declares, in Matthews vs. Murphy, is certainly a "right" or "estate." Then it takes up the question of whether a person having fitted himself for this learned profession, and having been licensed to practice the same, the state board of health has the right to charge him with "unprofessional conduct likely to deceive or defraud the public," and erect a standard by which that conduct is to be measured, and if in its judgment he does not meet its requirements summarily deprive him of a right or estate or both. Referring to the Kentucky statute bearing on the subject, one section of which provides that the board may refuse to issue a certificate to practice medicine to any individual guilty of grossly unprofessional conduct of a character likely to deceive or defraud the public; and it may, after due notice and hearing, revoke such certificates for like cause, the court remarks that the statute does not prescribe the manner by which a physician may regulate his conduct. It does not advise him in advance what act or acts may be in violation of its provisions. He is not told what is lawful or unlawful. He might do an act which he regarded as entirely proper, which neither violated moral law or involved turpitude, still such acts might, in the opinion of the state board of health, amount to unprofessional conduct, and which in its opinion did or was calculated to deceive or defraud the public. The physician who did the act of which complaint was made before the state board of health could not know at the time the act was done what standard would be thereafter erected by the board by which its effect was to be determined. As the statute does not advise him beforehand as to what is unprofessional conduct, he could not knowingly or intentionally be guilty of it. In other words, the legislature, in effect, has attempted to commit to the state board of health the right, after the physician has done some act, to determine what its effect is to be, and if, in its judgment, he should be deprived of the right to practice his profession, it can inflict the punishment upon him by revoking his license. Besides, what the present state board of health and diminution of the latter. This also occurs after repeated stimulation of the reflexes; the cutaneous reflexes become weaker and weaker while the tendon reflexes become more and more exaggerated. Contracture is an exaggeration of the muscle tonus and may be due to inhibition of the antagonist muscle, or to a lesion of the tissues surrounding the central or peripheral motor neurons. There is no essential difference between the contracture in convulsions and that of hemiplegia, but in the pseudo-contracture of hemiplegia, with retraction of the tendons, there is evidently some alteration of the peripheral motor neuron with interference with its trophic function. Muscular hypertonicity does not necessarily coincide with exaggerated tendon reflexes—another argument in favor of their anatomic independence. The amount of contracture is usually proportional to the vigor of the muscle. Although some disturbance in the central or peripheral motor neurons is the principal, if not the only cause of contracture, yet there is considerable difference between the contracture due to each.

Therapeutics.

[It is the aim of this department to aid the general practitioner by giving practical prescriptions and, in brief, methods of treatment for the diseases seen especially in every-day practice. Proper inquiries concerning general formulae and outlines of treatment will be answered in these columns.]

Removal of Lanugo and Hairs.

A subscriber asks for a safe method (not electrolysis) of permanently removing superfluous hair, especially lanugo of the upper lip of girls.

There is no method of permanently removing hairs other than by electrolysis. This should not be attempted in such cases as mentioned above. A growth of coarse hair will recur even after electrolysis.

Treatment of Pertussis.

Just at this time of year pertussis seems to be very prevalent in some localities. This time in the year is certainly favorable to the prognosis of the disease. The little patients can be kept in the open air, and not housed in close rooms, which lessens the number of paroxysmal attacks of coughing as well as the severity of the attacks. The medicinal treatment is divided into the antiseptic, the anti-catarrhal and the sedative treatment.

Yeo is convinced that carbolic acid inhalations is of great value in the antiseptic treatment of this disease. He places the child in a small room containing an open fire-place; a large iron spoon should be made hot from time to time and carbolic acid vaporized by putting a teaspoonful or two into the heated spoon. The atmosphere should be so strongly impregnated with this vapor, according to Yeo, as to make the atmosphere unpleasant to others. These fumes should be kept up night and day. As a spray for direct inhalation he recommends the following:

℞.	Acidi carbol.	ʒi	4	66
	Glycerini	ʒi	4	
	Sodii bicarb.	gr. x		
	Aq. destil	℥i	32	

M. Sig.: Use as a spray in front of the mouth of the infant constantly, so that he is compelled to inhale it.

The urine should be under constant observation during above treatment and if any discoloration occurs the treatment should be suspended for twenty-four hours.

FOR THE PAROXYSMS.

The following combination is recommended to lessen the severity of the paroxysm and to render the expectoration less tenacious:

℞.	Sodii benzoatis	gr. lxxii	5	20
	Sodii bicarb.	gr. xlviii	3	66
	Ammonii chloridi	gr. xxiv	1	
	Aquæ chloroformi	℥i	32	
	Aquæ anisi, q. s. ad	℥iii	96	

M. ft. mistura. Sig.: One to four teaspoonfuls according to the age of the child, in a little hot milk, every four hours.

Bamberger recommends the following the moment the attack comes on.

℞.	Sodii bicarb.		
	Sacchari, āā	ʒii	8

M. Sig.: Dissolve a small amount of the powder in hot water and give to the patient as the paroxysm of coughing comes on.

Dujordin-Beaumetz recommends the triple bromids for relief of the paroxysm as follows:

℞.	Ammon. brom.		
	Sodii brom.		
	Potassii brom. āā	ʒss	2
	Syr. chloralis	℥i	32
	Aquæ, q. s. ad	℥iv	128

M. Sig.: One teaspoonful or more according to age, in milk night and morning.

Roth recommends the following:

℞.	Acidi carbol.	gr. xv	1	66
	Spts. vini rectif.	m. xv	1	
	Tinct. iodi	m. x		
	Tinct. belladonnæ	m. xxx	2	
	Syr. papaveris	ʒiiss	10	
	Aq. menth. pip. q. s. ad	℥ii	64	

M. Sig.: One teaspoonful every two hours for a child between one and two years of age; half the quantity diluted with water for infants under one year of age.

HEROIN IN WHOOPING COUGH.

Dr. H. H. Haralson, of Vicksburg, Miss., recommends the administration of heroin, beginning early in the attack and continuing it through the catarrhal and paroxysmal stage. During the last stage he recommends tonics. good nourishment and proper hygienic surroundings. The following combination is employed by him:

R.	Heroin hydrochlor.	gr. ¼ to ½		015-03
	Tinct. belladonnæ	ʒi	4	
	Spts. frumenti	℥i	32	
	Syrupi simplicis, q. s. ad	℥iv	128	

M. Sig.: One teaspoonful every five or six hours.

Dr. Haralson seems to be very enthusiastic over his success in ameliorating the paroxysm and lengthening the time between the paroxysms as well as cutting short the duration of the disease.

TREATMENT OF WHOOPING COUGH BY IRRIGATION OF THE NARES.

W. Lattey, according to *British Medical Journal*, states that the irrigation of the nares in pertussis should be more frequently employed. The child should be rolled up in a shawl with the arms confined, and placed face downward across the nurse's lap. Tepid water should first be used with a soft india rubber tube attached to the syringe. This should be followed by some antiseptic solution. The same treatment should be carried out with both sides.

Treatment of Erysipelas.

J. Hays, in *Jour. de Méd. de Paris*, recommends the following as a lotion in the treatment of erysipelas:

℞.	Acidi carbol.		
	Tinct. iodi		
	Alcoholis, āā	ʒss	2
	Olei terebinthinæ	ʒi	4
	Glycerini	ʒiss	6

M. Sig.: For external application.

Every two hours the erysipelatous part may be painted with this liquid as well as a small zone of the surrounding healthy tissues, and the whole covered with aseptic gauze.

A Sedative in Tubercular Meningitis.

The *New York Med. Jour.* recommends the following, as advised by Malba, to combat the agitation, the cries and convulsions in tubercular meningitis.

℞.	Strontii bromidi	gr. xv	1	5
	Chloralis hydratis	gr. viiss		
	Syr. Valerianæ	ʒv	20	
	Syr. menthæ	℥ii	64	

M. Sig.: One teaspoonful every half hour until quiet is obtained.

Intestinal Tuberculosis in Infants.

The following is noted in *New York Med. Jour.*:

℞.	Argenti nitratis	gr. ii		12
	Pulv. amyli			
	Pulv. altheæ, āā	gr. v		33

M. ft. pil. No. xv. Sig.: One pill to be taken daily for three consecutive days after the administration of a light saline aperient.

If the diarrhea does not stop, the dose should be raised to two or even three pills daily during two consecutive days. This treatment is suitable for children ranging in age from 5 to 10 years.

For young infants the following is recommended:

℞.	Argenti nitratis	gr. 1/6		01
	Syrupi idei	℥iss	48	
	Aq. destil. q. s. ad	℥iii	96	

M. Sig.: From a dessertspoonful to the entire draught according to age once or twice daily.

Absorption of Drugs by the Bladder.

Barbiana, according to the *Ther. Gaz.*, has found by experimental research that dilute solutions of various drugs, with the exception of iodin, are never absorbed by the bladder at first irrigation, but that if consecutive irrigations are made there is fairly active absorption. This he attributes to certain functional disturbances of the epithelium incident to the mechanical action of the lavage upon the vesical walls, since such absorption may take place without further alteration of this epithelium. He believes that the complete retention is in itself sufficient to produce such changes in the vesicular wall as are calculated to encourage absorption.

Salivation Following Ether Narcosis.

The salivation in ether anesthesia is usually excessive and very often is a factor in the cause of bronchitis and pneumonia following its employment.

Dr. W. Reinhard, as stated in *Merck's Archives*, recommends the following as a preventive:

R.	Atropinæ sulphatis	gr. 1/6		01
	Morphinæ hydrochloratis	gr. iii		20
	Aq. destil. q. s. ad	ʒiiss	10	

M. Sig.: Inject from eight to sixteen drops, according to the condition of the patient.

Treatment of Umbilical Hernia.

The *Med. Record* makes a note of the treatment of umbilical hernia according to the method of J. C. Hubbard, by means of adhesive plaster strapping. He states that the younger the child the earlier the cure is to be expected. The failure of cure and the danger of recurrence are slight. The author reports 28 cures out of 60 cases.

Pelletierin Tannate in Tapewôrm.

The following combination containing pelletierin tannate has been used with almost uniform success in treatment of tapeworm, but it disturbs the stomachs of some patients:

℞.	Oleores. aspidii	ʒiv	16
	Olei terebinthinæ	ʒii	8
	Pelletierin tannatis	ʒi	4
	Spts. chloroformi	ʒi	4

M. Sig.: Shake well. One teaspoonful in the morning on an empty stomach followed in about two hours by a saline cathartic.

Treatment of Tabes Dorsalis.

Collins, in *New York Med. Rec.*, summarizes the treatment as follows: 1. The determination as to whether antispecific treatment shall be employed. 2. The utilization of electricity, hydrotherapy, massage and counterirritation. 3. The education of the ataxic members, the rehabilitation of purposeful movements. 4. The relief of subjective symptoms, such as pain, crises, dereliction of bladder function, ocular paralyses, amaurosis and trophic disturbances. 5. Adopt a plan of treatment and carry it through.

It might be added in addition to Dr. Collins' statements that the value of antispecific treatment is questionable unless the symptoms of tabes come on comparatively early after the infection. In other words, if tabetic symptoms do not make their appearance earlier than five years or if the syphilis in its active stage has received strong treatment the employment of mercury and the iodids is usually productive of harm. On the other hand, too much stress can not be placed upon the value of exercise to re-establish co-ordination after Fraenkel's methods, while inactivity and disuse greatly decrease muscular control as well as discourage the patient.

Medicolegal.

Basis of Recovery for Services as Health Officer.—The Court of Appeals of Kentucky holds, in Henderson County vs. Dixon, that where an action is brought for the recovery of compensation for services alleged to have been rendered as health officer, and the appointment of the claimant is traversed by the answer to his petition, it is incumbent upon him to prove the organization of the county board of health, and also his appointment to the position claimed by him. It is further of the opinion, too, that such appointment should be proven by the records of the county board, or some reason given for the introduction of oral testimony. Again, when the appointment is denied, it holds that it is a question of fact for the jury to find that the claimant was duly appointed, before it can, in any event, allow him any compensation. Then, complaint was made in this case of the admission of testimony, in this: that the witnesses, in fixing a reasonable compensation, were permitted to base their opinion as to the value of services upon the standing of the claimant as a physician. But the court holds that it was competent to show that he was a physician of good standing and of long practice, and that the jury might take such facts into consideration in determining the value of his services, though the criterion of recovery, if entitled to recover at all, was reasonable compensation.

License a "Right"—Validity of Act as to Revoking.—The license to practice medicine which one receives, the Court of Appeals of Kentucky declares, in Matthews vs. Murphy, is certainly a "right" or "estate." Then it takes up the question of whether a person having fitted himself for this learned profession, and having been licensed to practice the same, the state board of health has the right to charge him with "unprofessional conduct likely to deceive or defraud the public," and erect a standard by which that conduct is to be measured, and if in its judgment he does not meet its requirements summarily deprive him of a right or estate or both. Referring to the Kentucky statute bearing on the subject, one section of which provides that the board may refuse to issue a certificate to practice medicine to any individual guilty of grossly unprofessional conduct of a character likely to deceive or defraud the public; and it may, after due notice and hearing, revoke such certificates for like cause, the court remarks that the statute does not prescribe the manner by which a physician may regulate his conduct. It does not advise him in advance what act or acts may be in violation of its provisions. He is not told what is lawful or unlawful. He might do an act which he regarded as entirely proper, which neither violated moral law or involved turpitude, still such acts might, in the opinion of the state board of health, amount to unprofessional conduct, and which in its opinion did or was calculated to deceive or defraud the public. The physician who did the act of which complaint was made before the state board of health could not know at the time the act was done what standard would be thereafter erected by the board by which its effect was to be determined. As the statute does not advise him beforehand as to what is unprofessional conduct, he could not knowingly or intentionally be guilty of it. In other words, the legislature, in effect, has attempted to commit to the state board of health the right, after the physician has done some act, to determine what its effect is to be, and if, in its judgment, he should be deprived of the right to practice his profession, it can inflict the punishment upon him by revoking his license. Besides, what the present state board of health might consider unprofessional conduct might be adjudged by another board not to be. For such reasons, the court does not think the Kentucky statute is valid in so far as it attempts to confer upon the state board of health the right to revoke a license which has been granted by it to a physician to practice his profession. This conclusion, however, applies alone to so much of the statute as authorizes the board to revoke a physician's license to practice medicine for unprofessional conduct. That part of the statute which authorizes the board to pass upon the qualifications of persons to practice medicine and to license them, the court says, is valid, though if the board should exercise that power either arbitrarily or capriciously, the party injured may obtain relief in the courts. It also says that if the legislature desires to declare for what acts or conduct a physician's license to practice medicine shall be revoked, it is competent to do so, and to vest in some tribunal the authority to investigate and try the charge which may be made under such a statute.

Medical Books—Reputation for Skill as Abortionist.—The rule in Kentucky, as it is at common law, the Court of Appeals of Kentucky says, in Clark vs. Commonwealth, is that books on scientific subjects are not admissible to prove the facts treated of in them. But that is not saying that such books, or, more particularly, medical books, may not be read to the jury for any purpose, otherwise, as the court suggests, an ignoramus in a profession might, by an assertion of learning, declare the most absurd theories to be the teachings of the science of which he is a professed expert, and, when pressed upon cross-examination as to either his own experience or the basis of his learning, would be enabled to hide behind the formidable name of some standard author, and thus foist upon the jury a most hurtful falsehood as a scientific deduction, asserted by the most eminent in the profession, solemnly declared and promulgated by him for the guidance of his brethren and the service of mankind. Therefore, in a case where such a witness (as for example, a physician) makes such an attempt, it is just and reasonable, the court holds, that the opposite side should be permitted to test the truthfulness of his statement, and expose his ignorance or mendacity by either compelling him to admit upon an inspection of the authority that it does not sustain his views, or by reading the authority to the jury to prove that it does not, and that the witness, either through ignorance or base motive, has falsely deposed. Then, the testimony of all the medical witnesses in this case being that certain lacerations indicated that they were made by a bungler, the court holds that it was competent for the prosecution to show, if it could show, by those personally acquainted with the skill of the accused as a surgeon and physician, that they knew him to be unskilful. But it was not competent for the commonwealth to prove the extent of his skill as a surgeon or physician by hearsay or reputation. And when the commonwealth introduces evidence attacking the professional ability or skill of a defendant, it necessarily follows that he should be permitted to prove affirmatively that he is a skilled surgeon, and this he may do, if he can, by those acquainted with his skill; and certainly those who have been his patients, and have had the very best opportunity of judging of that skill, should be permitted to testify. What his reputation is can not be proved for him any more than it can be against him, the question being as to what is the fact as to his being skilful. Evidence having been suffered to go to the jury from which it would appear that the accused was a professional or habitual abortionist, the court says that if it was shown or admitted that he had committed the abortion charged in this case, but attempted to justify it upon the ground of necessity, it is clear that the evidence would have been competent to prove his motive and intent, and to rebut or negative the idea that he was acting upon his professional judgment, and under a necessity of saving the life of the mother. On the other hand, as the purpose and effect of the evidence in this case was not so much to show intent or motive, as it was to establish primarily the guilt of the accused as to having perpetrated the act of abortion, in the opinion of the majority of the court the admission of this evidence was error, and it should have been rejected.

AMERICAN.

1. **Epileptic Colonies.**—The conditions for an ideal epileptic colony are discussed by Spratling, who insists on the importance of good water supply, drainage, etc. As regards location, he objects to too easy accessibility by outsiders, but still would wish to be in reasonable proximity to the centers of population from which the patients are received so as to have the advantages in obtaining supplies. He dwells on the importance of attractive landscape gardening and the value of the colony plan rather than large buildings containing great numbers of patients, and mentions the following requisites for colonization: 1. An administration building; 2, hospital building, complete and modern for the treatment of medical and surgical cases and having attached to it wings for receiving recent admissions. 3. Industrial buildings for educational and other purposes, proper farm equipment and a number of patient's cottages which he divides into three classes: 1. Those holding from 12 to 16 or 18 patients. 2. Those large enough to accommodate from 25 to 35, the most numerous class. 3. Infirmaries combining home and hospital for the use of perpetually bedridden and infirm patients. Homes for the employees should also be provided. The resident officers should include a medical superintendent, appointed by the managers, four or five assistant physicians, medical internes, pathologist, etc., these all appointed by the superintendent. The ratio of medical officers, not including the pathologist, should be one to every 100 patients. Other officers, such as steward, chaplain, matron, etc., should also be appointed by the superintendent and a training school for nurses should be an important feature of the institution.

3. **Gastrectomy.**—The advisability of complete excision of the stomach is treated of by Childs-MacDonald under the following heads: 1. The diagnosis and age. He would limit the operation to 55 in men and 60 in women, though this must not be absolutely the rule, as individuals differ. 2. The state of the blood. A high percentage of white cells means an unfavorable prognosis. 3. The absolute integrity of the heart, nervous, muscular and valvular, must be considered. A weak diffused pulse, arteries insufficiently filled, plus loss of tone, cardiac dilatation, organic valvular lesions, marked hypertrophy and muscular insufficiency, evidence of previous heart strain, atheroma, delirium cordis, irritability, all should prohibit operation. The heart should be in the best possible condition, or the patient's life may be lost by cardiac failure or shock. Other things being equal, workingmen and women furnish a more favorable prognosis than those who follow a sedentary or idle life. Total abstainers are favorable, while over-indulgence in liquor is a positive bar; even moderate beer drinkers are not good subjects. We must be sure there is gastric cancer and its location. The most favorable indications are a moderately dilated viscus with freely movable tumor situated to the right of the median line. A contracted or very dilated stomach, with a fixed or non-palpable tumor, or one located on a line extending from the center of the epigastrium to the anterior superior spine of the ilium on the left are decidedly unfavorable. Adhesions may be expected with all their complications, or disease may arise external to the stomach. If we have any grounds for suspecting that the disease has implicated the cardia, we should on no account attempt any operative procedure except to establish an opening between the stomach, jejunum or duodenum and skin, through which the patient may be fed. Twelve or fourteen months previous disease contra-indicates operation, while metastasis is an absolute bar. 6. The preparation of the patient should include absolute rest in bed for four or six days or more, with attention to excretions. Lavage of the stomach once in twenty-four hours, preferably at night, with some mild antiseptic, will relieve pain and lessen the catarrh. The patient

should be frequently and judiciously fed, to the capacity of his powers of assimilation, with peptonized milk, broths and gruels, both by mouth and rectum. The mind must be kept quiet and the patient amused. The liver and bowels should be kept active with small and repeated doses of podophyllin resin, in combination with similar doses of calomel followed by salines. The skin should also be treated with warm baths with soft green soap dissolved in alcohol. In addition to the food mentioned he gives 3 ounces of beef tea made by the cold and hydrochloric acid process. Food should be given every two hours during the day and twice during the night. Alcohol in the form of old pure brandy, well diluted, should be administered to the amount of 4 ounces in twenty-four hours at regular intervals; it strengthens the heart and retards waste. For the final two days he prescribes 1/100 of a grain of digitalin three times a day. The stomach should be well washed and a rectal injection given on the morning of the operation.

4. **The Outlook of the Medical Man To-Day.**—Dodson points out that only a moderate income can be expected as a rule from medical practice as compared with other successful occupations. He advises the physician to gain general culture outside of his own profession, not to neglect his social and political duties, but especially to remember that besides the care and study of his patients the largest hope lies along scientific lines. He points out that certain physicians have, under conditions that were not particularly favorable, done highly scientific and extensive work. For instance, there are physicians in small towns who conduct surgical clinics with success. Industry, honesty and a love of truth are essential.

5. **The Contagiousness of Tuberculosis.**—Shurly analyzes 130 cases observed during the year 1898 and finds that of these there were 9 doubtful cases. Of the remaining 121 there is a possibility of 9 only having originated through ordinary natural communicability; while on further analysis there is a possibility that only 5 so originated, and further, that of the whole number, 130, at least 112 were immediately preceded by some acute or subacute disease. The tendency of his paper is to minimize the importance of case-to-case contagion in consumption.

6. **Carcinoma of the Breast.**—In this condition the question of successful operation depends so much on its early performance that diagnosis becomes only secondary to treatment. Vischer finds that 80 per cent. of breast tumors were of this nature, while of the remainder 4 per cent. were sarcomas and the balance such as frequently undergo malignant change. He divides the breast for clinical purposes into four quadrants by two lines passing at right angles with the nipple. It is found that carcinoma is most frequent in the upper outer, and next in the lower outer quadrant. Sarcoma, a much rarer growth, is found most commonly in the inner upper segment. Retraction of the nipples is found comparatively seldom, and only where connective tissue enters largely into the formation. The form beginning with adenoma, gradually assuming epithelial change, is rather common, and is found in young women. The medullary form is most rapid in growth and shows an early tendency towards breaking down. Nodulation is significant of connective tissue hyperplasia and is of less importance than the mobility of the growth and its anatomic situation. The prime object of this paper is to attract attention to the early recognition of the condition. He suggests careful observation of any breast that has ever been the seat of inflammation. Attention is not apt to be called to this condition as subjective symptoms are few in the early stages. Of the 56 cases of removal occurring in private practice, of which he had a complete record, only about two-thirds have recovered. In multiparas, past the age of lactation, it would be far safer to remove all breasts which are the seat of tumors. In breasts that have had abscesses, any enlargement should be sufficient cause for removal.

7. **Influenza.**—Three cases are reported by Kernodle of la grippe in old people, showing peculiar nervous and urinary manifestations. Summarizing these he thinks that aged persons suffer more violently from la grippe than those in youth and vigor; the manifestations are more marked and profound in the aged; and never entirely disappear; nephritis and urinary disturbances are more pronounced and lasting, and there is a more decided tendency to recurrence, resulting in death; owing to the worn-out and deteriorated physical condition and lowered nerve resistance the results are more grave, the assaults more violent and profound and the death rate much higher in persons over 50 years.

8. **Traumatic Hysteria.**—Hysteria is a misunderstood condition, being a mental disease with physical manifestations. Bailey reports a number of cases illustrating this point. He thinks there is uncertainty regarding the prognosis in this as in all other mental affections. The patient may recover or may be a sufferer for years. Of the indications which enable us to make the prognosis, he mentions first heredity, but believes that it is very difficult to substantiate the teachings of Charcot that hysteria never develops except in degeneracy. Age is an important matter, and he believes that in healthy persons not over 35 or 40 years of age the chances of recovery are good, though not certain, but that, with increasing age, the chances become less. He thinks that immediately after an accident, if the patient could be isolated and cared for by a physician who understood the significance of the symptoms and the best way of treating them, we would have very little persisting traumatic hysteria. Such ideal conditions, however, are rarely possible, and sympathy, indulgence and suggestion may render the disease hopeless.

9. **Infantile Typhoid.**—Strasser has found in the majority of his own cases symptoms of typhoid infection at the end of the second week. The cases run about as follows: Few prodromata; incubation not noticeable; headache not severe in infants, though it may be intense in older children; both are liable to initial convulsions. The fever is usually the cause of anxiety and the call for the doctor. It runs a wide range, and is usually more or less rapid, though conforming somewhat to a fairly typical typhoid curve. The state of the bowels is of no diagnostic value. Bronchitis is common, remaining long in the congestive stage. Epistaxis may be quite frequent; the tongue is not characteristic; rose spots occur as in adults; there may be some suppression of urine and splenic enlargement is frequent, according to some authorities. The main symptom is subacute bronchial inflammation due to the excretion of the Eberth bacillus from the bronchi and this in children amounts to the main disease for the first few weeks. He reviews Jacobi's statement of the dangers of typhoid in children, and agrees with Noyes that, in spite of these, convalescence is more rapid than in the adult, the mortality is less and abortive cases are more frequent. The prime requisite in the treatment is an intelligent nurse. When the temperature reaches 102.5 or 103 F. and there is great irritability, threatening convulsions, and severe headache, it is time for the cold bath and pack. As regards antipyretics, he does not favor them. As to other medication, salol is good; in diarrhea the various bismuth preparations are best. If constipation is the feature, calomel is the best antiseptic. When there is perforation or even slight hemorrhage, turpentine is the internal sheet anchor, and for very distressing meteorism, it is very comforting in the form of stupes or enemata. Rest in bed, the use of fluid food, etc., are not necessary to mention. He warns against the use of ergot preparations for hypodermic injection. Convalescence should not be retarded, nor should solid or semi-solid food be withheld too long.

11. **Zoological Distribution of Tuberculosis.**—Hutchinson has studied for five years the mortality in the London Zoological Garden and finds an apparently greater susceptibility to tuberculosis among vegetarian animals and a much reduced susceptibility among meat eaters both in mammals and birds, though there are some serious exceptions to the apparent rule. The odd-toed ungulates among the vegetable-eaters have important resisting powers and seldom become infected. He finds the largest percentage of tuberculosis among the primates, and the lowest amongst the carnivora and marsupials. In birds the greatest percentage is among the gallinæ and the lowest among the raptores. The American monkeys which

take some animal food are much more free from tuberculosis than the old-world catarrhine form. As regards housing, he finds that the animals that can stay in better air are less affected. The carnivora seem in most cases to demand a higher degree of activity than the herbivora, and when from any cause this higher degree of vigor and dash has been acquired by herbivora, then immunity from tuberculosis follows. The conclusion to which this preliminary survey has led him is that the distribution of tubercle is a matter of vigor, endurance, and resisting power, rather than of race, food, or exposure to infection, and as these powers are usually higher in flesh eaters than in vegetable feeders, the former possess a marked relative immunity.

12. **Bifocal Lenses.**—Weeks discusses the disadvantages of these glasses and finds that after experiments with various devices, the best results can be obtained by the use of a paster of oval shape, which measures 10 mm. in its vertical and 15 mm. in its horizontal diameter, giving a field at the reading distance of approximately 7 in. in the horizontal, and 12.5 cm. (5 in.) in the vertical meridian. If the oval disc is placed 2 mm. above the lower edge of the distance lens it will permit of clear distance vision below, sufficient to enable the wearer to see the curb, descend stairs, etc., without trouble. It is sufficient to place the optical centers of the portion of the lens for reading at the center of the paster. The dispersion rays of light occasioned by the edge of the paster can be minimized by making the edge very thin. In his diagram he places the paster a little to the inner side of the center of the larger lens.

13. **Actinomycosis Hominis.**—The case reported by Fütterer is thoroughly studied, and he says in conclusion: That macroscopic diagnosis between actinomycosis and tuberculous peribronchitis is possible and not even difficult. In actinomycosis he finds small, sharply-defined, sulphur-yellow rings, with clear, round outlines, having little tendency to involve the lung substance. These rings show a decided tendency to grow toward the center of the lumen of the bronchus, which at last becomes entirely occluded. The color is important, for in tuberculosis this varies. Where there is caseation even, the yellow color has a more grayish tinge and is not uniform in quality. The tuberculous areas project above the surrounding tissues and have an uneven surface and irregular outline; there is not the same tendency to grow centrally and close up the lumen, but rather to spread peripherally and an early affection of the surrounding lung tissue is the rule. Tuberculous infection generally affects the apices first, but actinomycosis prefers the lower parts of the lungs.

15. **Hip-Joint Disease.**—The conclusions presented by Lovett are as follows: Cases of hip disease permitting not over 25 degrees of motion in flexion or extremely irritable cases should be treated by the best obtainable fixation plus traction. Treatment by recumbency is not generally necessary even in the most acute cases, if the apparatus described above is applied to the hip in the position of deformity. This deformity generally disappears under this treatment. The splint should be removed as seldom as possible, and the hip should not be disturbed by frequent examinations. Cases allowing 25 to 45 degrees of motion in flexion may be treated by Dane's splint with high shoe and crutches in preference to any other form of traction splint. Personally, he would extend the use of the spica traction apparatus to most of these cases in the hope of shortening the disease by over-efficient treatment, but that position could perhaps not be successfully defended. The use of the Davis-Sayre-Taylor long traction splint, with one or two perineal bands, should be limited to cases allowing well over 45 degrees of motion in flexion, and should be used with high shoe and crutches to prevent the intermittent traction necessarily incident to walking on the splint. It is probable that the more rational use of combined traction and fixation would lead to better results in conservative treatment in shortening the disease and improving the functional results than can be obtained by the routine use of traction.

17. **Climate in Tuberculosis.**—Gardner pleads for the importance of change of climate as a matter of treatment in tuberculosis. He claims that by change to a high, dry region, the organism undergoes formation of new cells, nutrition is stimulated, and isolation of tuberculous tissues is more rapid. In the winter the cold is more endurable and more beneficial than at lower altitudes, and the continuous sunlight is an effective germicide. The dryness of the air and the cool nights prevent exhaustion in the summer time. The electrical conditions are stimulating, The scenery has a physiologic value often overlooked. Climate comes in as such a factor that 15 per cent. better results can be obtained under home treatment of tuberculous cases in Colorado than in closed sanatoria in the East.

19. **Tuberculin.**—Otis has experimented with tuberculin as a diagnostic test in 36 cases of syphilis, or 35, throwing out one doubtful case. There were 6 undoubted reactions and 5 which he calls abortive reactions. Considering only the 6 we have 17 per cent. of reactions; including the abortive cases, we have 31 per cent. He does not find with Beck that one-half the cases of syphilis react to this test, but there does not seem to be any guide in the activity or quiescence of the disease as to whether or not the reaction is likely to occur. In his most violent reaction, in which the temperature went up to 104, the case was one of many years' duration and without active manifestations. He also examined 26 cases of suspected or proven tuberculosis, which gave some interesting and perplexing results. In 8 cases where the physical examination showed sufficient evidence of tubercle or where bacilli were found in the sputum, he had 4 reactions and 4 failures. In 3 cases where the tubercle bacilli were found in the sputum, 2 did not react. In one 7 milligrams were used and in the other 5 and 10. In the third case where 2, 5 and 8 milligrams were successfully used only a local reaction was obtained. He offers no explanation for such results. Of the remaining 18 cases of suspected tuberculosis there were 6 reactions and 12 failures. In none of the cases which failed to react could tuberculosis be more than suspected. A case of lupus of the face, besides giving a general reaction, showed a pretty local one. In using the tuberculin test for suspected tuberculosis, experience, he says, teaches us to look carefully for syphilis. He confesses that when he has a case of tuberculosis with tubercle bacilli in the sputum and failure to reaction, his confidence in the test is somewhat shaken, but it is well to bear in mind that there is always a chance of error and that we do not yet know what the minimum efficient dose is.

20. **Burns.**—Burns, according to Griffith, may be divided into two degrees of severity, the first class involving the skin only and the second including all others. The pathology of these is that of inflammation of the part locally affected. Early death and internal complications are due to direct action of heat, with fragmentation and vital change in the blood corpuscles. Later effects are due to infections taking place from the burned area. The granulations during the healing of burns are the determining factor in the amount of contraction and deformity. The greater the friction caused by irritation of any source, the larger the granulations, the greater the amount of connective tissue and the contraction. The local treatment from the earliest times has been along the lines of prevention of irritation, but the late advances in wound treatment have not been followed. The burned wound should be cleansed with the removal of as much burned, dead tissue as possible; the thoroughness with which this is done will determine the presence or absence of infection. Hydrogen dioxid to wash away the debris and render aseptic the denuded parts is the best antiseptic at our command. Rubber tissue in strips should be laid on the wound to prevent contact with absorbent dressing. The use of splints to secure relaxation and retention in obtaining rest for a burned part is of great importance, and is as much indicated in this form of injury as in fractures. The internal treatment is stimulative until reaction from shock has taken place, when it becomes supportive. Opium fills the indications for pain, internal inflammation, and diarrhea. The bowels and kidneys should be continually kept open, but enemas only should be employed.

Watchful attention must be given to early signs of internal complications of viscera.

21. **Carbolic Acid in Burns.**—Three cases are reported by Muench, one of his own experience and two others, in which pure carbolic acid was applied to burns, causing immediate cessation of pain with no subsequent swelling or inflammation. The corroded skin came off in a few days, leaving a new skin and causing absolutely no inconvenience or trouble, not even a scar or contraction of muscle. In one case the burn was very extensive, covering the entire head, face, neck and hands, and in this case he gave a hypodermic injection of morphin. The patient recovered without a single scar, although there was sloughing on the end of the nose and rim of the ears.

22. **Petroleum Compounds.**—Reyburn calls attention to the inertness of petrolatum when given internally. He says it passes unchanged through the intestinal tract and therefore is insoluble in the gastric juice and intestinal canal and can be recovered as a whole in the feces. Its usefulness as a remedy, therefore, must depend on its unirritating and demulcent properties.

24. **Delirium Tremens.**—Perry has no sovereign remedy for delirium tremens. He does not believe in the sudden withdrawal of alcohol in chronic habitués. It is his practice to put the patients on a liquid diet as nutritious as can be borne, a goodly quantity every two hours during the day. In mild cases he stops the alcohol at once; in severe ones it is seldom completely withdrawn before the fourth or fifth day. The quantity, however, is lessened and as substitutes he uses ammonia, camphor, hyoscyamus, valerian, capsicum, ginger, etc. The heart must be supported by strychnin, nitroglycerin, etc., and small doses of opium may be employed. He thinks chloral hydrate, alone or combined with potassium bromid, one of the best things there is in some conditions of insomnia. He has employed hyoscin hydrobromate, though this is not a safe remedy. A better agent is musk, but its high cost is prohibitive in many cases; apomorphia properly used is safe, but is usually pushed too far, as has been the case in the drink cures. Morphin is not constant in its action; in most cases it is quieting, but seldom efficient alone. When the patient goes to sleep he must not be disturbed, though the sleep may last fourteen or fifteen hours. The attendant should be fearless and humor the patients in a practical way. Some patients, however, are extremely obstinate, and may require restraint, though only as a last resort. Lying on the back, a spread eagle is made of the unfortunate by towels and sheets. The patient will tug at his fastenings and be irritated, but is finally exhausted and possibly will fall asleep.

25. **The Effects of Alcohol.**—Beyer finds alcohol is primarily a stimulant, but a protoplasmic poison. He criticizes Dr. Woodruff's expressed ideas as to its value in the tropics. He has seen very little good from giving it in tropical climates, though in some cases for temporary purposes he has employed it in the engine and fire-room force—one ounce of whisky every twenty-four hours. The temperance movement generally has done much good, and he mentions an experiment of practical total abstinence in a recent Dutch expedition in the East Indies with extraordinarily good results.

26. **Delirium Tremens.**—Ellsworth differs from Perry in that he would cut off alcohol in every case, give milk and water abundantly and avoid hypnotics. In his experience with over 500 cases, he has never used restraint or allowed alcohol. He has had only two fatalities, and these patients were in a state of collapse when he received them. He attributes his success to the perfect freedom he allows the patients, that is, in not hampering their movements, in keeping the room thoroughly ventilated, giving good nourishment at short intervals, and the absolute prohibition of alcohol. He reports a case.

27. **Myomectomies.**—Baker reports a case of myomectomy, and in reviewing it makes the following suggestions: 1. The importance of performing myomectomies in preference to hysterectomies in most of the cases of fibroids during the child-bearing period. 2. Even though the patient and her friends may prefer a total hysterectomy for various reasons, principally among which are the facts of the extreme suffering of the patient or the great loss of blood, which make them desirous of absolutely putting an end to the menstrual process, it is generally better surgery to remove the cause of the suffering, and leave the uterus and ovaries in a state which may be of great future usefulness and certainly able to perform their normal functions. 3. The greater length of time necessary to perform several myomectomies in any given case is usually more than overbalanced by the complete insurance of the integrity of the organs involved.

29. **Intimate Action of Silver Nitrate.**—Mays bases his treatment on the theory that pulmonary tuberculosis is, in the majority of cases, primarily a neurosis in which the vagi participate and that the pulmonary disintegration is secondary. He believes direct stimulation of the vagi favorably influences the condition of the lungs. The mechanism of silver nitrate injections is of such a nature as to stimulate the vagi to a more vigorous action and in this way they create antagonism to disease that diffuses itself throughout the manifold ramifications of these nerves.

36. **The Cleansing of Floors.**—Owen recommends a finish on hospital floors of wax, linseed oil, turpentine, floor finish and benzine in the following proportion: Wax, 5 pounds; linseed oil and turpentine, 2 gallons each; floor finish (permanere), 1 gallon, and benzine, 10 gallons. This is applied once a week and laid on with a piece of cotton, brushed and polished with a cotton mop. He believes that too much floor scrubbing is responsible for some of the sickening odors which are due to decomposition taking place both in and on the floors. The danger of fire from the use of this material is very slight if only a small quantity is kept on hand to use at a time.

40. **Intraperitoneal Rupture of the Bladder.**—In case of intraperitoneal rupture of the bladder treated by laparotomy, it is evident, according to Alexander, that successful results in every case depend upon three things: 1. Surgical interference at the earliest possible moment after the accident. 2. Thorough cleansing of the peritoneal cavity. 3. Perfect closure of the bladder wound by sutures. The great object of the operation is to prevent peritonitis and septic infection, and he asks how can we prevent delay of operation in these cases and suggests that suprapubic incision, and exploration of the prevesical space is the best method. The injection and infiltration tests are liable to be misleading and are dangerous. Asepsis of the peritoneum can be best obtained by thorough flushing of the cavity with hot normal salt solution. For closure of the bladder wound he has used silk, that is, a layer of interrupted Lembert sutures and a second layer of crossed mattress sutures. The main point is not the suture material, provided it will not be too quickly absorbed, but the manner in which the suturing is done. He reports an operation and gives a tabulated statement of cases from the literature.

41. **Torsion Strangulation of the Testis.**—Scudder reviews the conditions and the literature of this disorder and finds that, in the majority of cases, its causes are rather mysterious, though slight trauma may produce it. He has found 31 cases in the literature and reports an additional one.

42. **Fracture of the Carpal End of the Radius.**—The different forms of possible fracture of the carpal end of the radius are discussed and illustrated both by diagrams and skiagraphs. The advantages of the Roentgen ray in this injury are recounted; they have thrown new light upon its possibilities. Beck concludes that in many cases of fracture of the carpal end of the radius producing so-called sideward pushing of the ulna, there is, in fact, a fissure or fracture of the ulna which was not recognized in former years, and this is seen only through a good skiagraph made with a good tube. The treatment of the different forms is described and the importance of perfect replacement insisted upon.

43. **Saddle Nose.**—The operation of Gwyer is described as follows: A longitudinal incision in the middle line at or near the root of the nose, depending on the amount of deformity

and carried downward towards the tip of the nose. At a point depending on the conditions existing, the line of incision divides into two lines separating more or less and coming together again below the tip, forming an ellipse. The skin included in the ellipse is removed. The skin is then dissected loose for a sufficient distance on either side, especially in the region of the deformity. A flap is next dissected out of subcutaneous tissue, and perhaps cartilage, starting at or below the tip and raising the flap as far as the lower end of the depression. The flap is made thicker in the middle than at the sides or ends and the thickest part placed in a position corresponding to the most depressed part. It is better not to carry the upper end of the incision too high, but having loosened the skin at that point, to tuck the free end of the flap under it. Such a course makes a smaller scar and union is prompter and firmer. After raising this flap, a portion of the cartilage lying on either side of the median line of the tip is removed, the amount depending on the spread of the nostrils. The suturing should be done with a small needle, preferably with horse-hair. The approximation should be very accurate and not too tight. The stitches should be removed as soon as possible. The quantity of skin removed in the ellipse depends on the amount of broadening of the tip and alæ. A narrow piece should be first removed, and subsequently more if necessary. The skin is then approximated with very fine sutures throughout the length of the incision, a figure-of-eight suture being used at the tip to approximate the deeper parts, and the wound is covered by a light dressing of collodion, iodoform and gauze. The advantages of this operation are, in his opinion: 1. The absence of foreign bodies. 2. Correction made with living attached tissue, having its own blood supply. 3. Ability to correct at the same time minor deformities. 4. Having the field of operation in sight. 5. A minimum of scar.

44. **Agar-Agar Injections for the Production of Connective Tissue.**—Kramer has experimented with melted agar jelly introduced in the fluid state into one side of the chest in rabbits. The animals were killed after a varying number of days. In the animal killed forty-eight hours after injection there was found a mass that had lost the gelatinous appearance of jelly and resembled an antemortem heart clot more than anything else. On microscopic examination it was found that the jelly had become honeycombed with small round cells. A section taken from a mass obtained from an animal killed after seven days showed still further infiltration and signs of beginning degeneration. In one taken after twelve days there were many fibroblasts and new blood vessels beginning to be formed. The mass of agar jelly at first infiltrated by small round cells is being replaced by vascularized connective tissue. After thirty days a newly-formed blood vessel could be plainly seen in the section. He thinks these experiments will be found to be of some surgical value. It is very often desirable to produce an artificial growth of connective tissue by means of some such injection. In several cases of inguinal hernia the sac and canal have been filled with the material, which has become organized and cured the defect. The permanency of the cure will be determined only by time.

45.—See abstract in The Journal, xxxvi, p. 1582.

51.—See abstract in The Journal, xxxvi, p. 126.

55. **The Insanity of Adolescence.**—Pickett analyzes 58 cases of dementia and finds that a considerable proportion of these occurred in patients whose insanity began between the years of 15 and 30. He shows by a graphic method—a sort of birdseye view—that the great majority of cases come under what is called katatonia or the dementia precox of Kraepelin. On the average, two-thirds of the cases met with at the Philadelphia Hospital between the ages of 15 and 30 become chronic dements or die of intercurrent disease, an important clinical fact. He insists on the importance of using prognosis as a basis of classification, making the conventional forms only a primary and secondary classification for convenience sake.

63. **Pulmonary Tuberculosis.**—Lewis discusses the diagnosis, etiology, symptoms, prognosis and treatment of tuberculosis. As regards heredity he thinks there is little reason to consider it important, but he believes also that the human system is normally resistant to the invasion of tubercular germs. The predisposing cause is, in fact, decrease of vital resistance or special susceptibility. The exact nature of this is little known; it probably consists of a certain chemical or histological condition of the lymph nodes due to hereditary tendencies or conditions of environment, which fail to arrest or inhibit the growth and the ingress of germs; or second, of some retrograde metamorphosis of the structure in any part of the body, generally in the lungs, or a trophic, traumatic or toxic influence favoring the invasion. Among the causes which diminish the vital resistance he puts air starvation first, either deficient supply of good air or incapacity to receive it. Next to this come gastrointestinal disorders. The symptoms are discussed at length. He does not lay great stress on the absence of tubercle bacilli, for they may not be readily found. The temperature range is one of the earliest symptoms. He is in the habit of loaning an accurate thermometer to intelligent patients so that they can keep a two or four hour record of their temperature. Cough is also a symptom of which patients may make little; it is not necessarily spasmodic. Emaciation is a symptom of much importance. The symptom of early hemorrhage has not been, as a rule, common in the incipient stage in his experience. The physical signs are briefly noticed and the principal points of the diagnosis are, in his opinion, careful attention to the temperature range, character and frequency of the pulse, cough, changes in body weight, and sputum examinations. The prognosis is far better than it used to be. We should build up the vital resistance, encourage regular habits, use hydrotherapy, good nutrition, and compulsory notification. He believes in over-nutrition. He considers raw eggs excellent, and thinks that as many as ten or twenty a day are justifiable in feeding. Of all the drugs that have been tried, strychnin stands at the head and he would give it freely. Next to this comes arsenic and if the cough requires some amelioration, guaiacol carbonate combined with codein or heroin is very efficient. He has little faith in creosote. Atropin may be useful in night sweats. The average patient is markedly benefited by an alcohol bath and rub down at bedtime. Alcoholic stimulants have very little use internally. While admitting the importance of the stomach and its condition as pointed out by Osler, Lewis would go farther and show that the cure depends entirely upon absorption, assimilation of nutriment. If the body metabolism is such that its tissues are able to acquire an amount of nutrient and reconstructive material greater than the general waste, the patient will live, if not, he will die.

64. **Management of Fevers.**—Love insists on the importance of attention to the digestive tract in fevers particularly. He thinks that the liberal use of water and flushing of the alimentary canal are beneficial. In the management of fevers of whatever origin or cause he recommends the following: 1. Prompt, potent purgation. 2. Keeping up the action of all the eliminating organs to their full extent, and, the lungs are the most important of these, an abundance of oxygen, and after this comes water in abundance. 3. Intelligent attention to nutrition, which demands the complete withholding of food in the beginning for several days and later only the blandest and most digestible foods in small quantities. The pushing of food can not be safely done until the secretions have all been corrected, and it is evident that the digestive organs are in no way crippled. 4. Temperature can be best held down and the nervous strain tranquilized by hydrotherapy and flushing and the easiest way is the best. The cold bath not only helps the excretion, but quiets the fever. 5. We may also use gentle manual massage and even some of the manipulative methods of the osteopaths for soothing purposes and as a stimulant and tonic. 6. Sleep. Complete rest at proper intervals, physically and mentally are essential. 7. "The Big Four Route" to health in all diseases including fevers is first, elimination; second, disinfection; third, nutrition, this means little or no food during the acute stage including stimulation, and fourth, tranquilization—rest. 8. We should not ignore the psychic elements and we should lead the patient in

the direction of his best good. We should study disease not less, but man more.

67. **Division of the Fee.**—Gillespie reviews the question of remuneration to the physician and consultant, especially the surgeon, and suggests the following propositions: "1. That division of the fee is just to the physician, surgeon and patient, when a surgeon is called to operate and is assisted by the physician in preparation, operation and after-treatment. 2. That cases referred to a specialist for treatment or operation, without the assistance of the physician, belong to the specialist. No commission should be paid or received, hence no division of the fee. 3. That cases referred from the country to specialists in the city belong to the operator, as he assumes all responsibility of preparation, operation and after-treatment, and no fee or commision should be paid. 4. That a specialist, visiting the country for the purpose of operating only, should divide the fee with the attending physician who has charge of the case or for whom he operates. 5. That the general practitioner in the city should conduct financial matters, collect the bill and pay the surgeon what is agreed upon between them; and that with this arrangement the patient has nothing to do. 6. That a commision paid to the layman or commission as such paid to any one is wrong, unjust and unethical. 7. That the question of the division of the fee or the payment of commission should, if possible, be settled; that it is of necessity a condition difficult to reach by expedients available to the profession. 8. That the objects sought for are satisfaction, not disappointment for the patient, and a profitable visitation for the general practitioner and specialist, both present and prospective."

68. **Ophthalmia Neonatorum.**—Blitz recapitulates his views by insisting on strict antisepsis before birth; the nurse washing the eyes of the new-born first, before the rest of the face, head and body, using a sufficiently strong disinfecting solution at once when sure or suspicious of gonorrhea in the mother; but a mild cleansing wash only when no disease exists in the vagina. The eye should be inspected daily during the first week after birth, if possible; if impossible, the nurse should be instructed to report at once any signs of inflammation. If it is a case of true ophthalmia blenorrhoica, treat it promptly. Employ absorbent cotton in cleansing the eye: never using the same piece twice. Persist in the same treatment until inflammation has disappeared and the greatest possible amount of vision restored.

72. **Pneumectomy.**—After noticing a case in which there was an abscess destroying the right lung, relieved by operation for empyema, Jacobson reports his experiments on dogs in the removal of lungs. The case suggested to him that such an operation would be possible without destroying life or causing serious injury. Seven dogs were operated upon, in six of which there was total resection of the right lung and in one the removal of the upper two lobes. Of the total resections, 3 died and 3 lived; in none of the cases was the death directly due to the operation. The experiments prove that the removal of the entire right lung is possible and that one lung is sufficient to carry on life in comfort. The dangers of operation are two, pneumothorax and secondary hemorrhage. The best method of combating the former seems to be by the use of the Fels-O'Dwyer apparatus for artificial respiration during the operation. The complication of secondary hemorrhage presents difficulties which are not so serious and the author thinks that the use of the angiotribe as suggested by Murphy would be of decided advantage.

76. **Gastric Ulcer.**—The operative procedures in cases of gastric ulcer are treated of by Howitt. He first notices the operations for ulcerative stenosis of the pylorus for which pyloroplasty should be preferred, the part being as well as possible brought into view, the peritoneal cavity guarded with sterile gauze, and the ulcer removed by elliptical incision running in the long diameter of the parts, the length depending on the amount of contraction. It is then sutured in such a manner that when closed the line of union is at right angles to the original incision. In a large proportion of cases, however, this ideal operation is not possible and gastro-enterostomy is desirable. Two practical points are specially insisted upon: 1. To make sure that the proximal arm of the jejunum is sufficiently long to prevent tension in any possible movement of the stomach. 2. To anchor same arm to stomach wall with sutures just above and an inch or more to the right of point of anastomosis. This last does away with the spur or acute angle of the bowel, and prevents untoward events which frequently prove detrimental after gastro-enterostomy. In hour-glass contraction of the stomach, several methods have been suggested; some prefer gastro-anastomosis. Gastro-enterostomy is the only safe course when the hour-glass contraction is near the pyloric orifice and complicated by adhesions and inflammatory thickening of the parts. In perforating ulcer he thinks that as soon as we are satisfied it has taken place, it is good practice to give morphin hypodermically. It relieves suffering, mitigates shock and lessens the amount of anesthesia. It is good practice to eviscerate the bowels as soon as the incision is completed and protect them with sterile gauze, kept warm and moist by irrigation. This gives us ample room for thorough inspection. When the trouble is in the posterior wall near the esophageal opening, it may be impossible to excise the affected spot, in which case it may be inverted and closed by layers of sutures. The abdomen should be thoroughly flushed, care being taken with each flank, the pelvic cavity, and lesser peritoneum. On replacing the bowels it is good practice to spread the omentum carefully over and fix it below with sutures to prevent the coil becoming adherent to the line of incision. Care should be taken after suturing, to dress with dry sterile material and seal so as to prevent infection by discharge through the drainage tubes. The author advocates this practice of evisceration and temporary enterotomies to let out the gas accumulations, because it reduces shock, makes work easy, relieves bowel distention, permits the escape of germ-laden material and renders later vomiting and paralysis much less probable. The after-treatment consists of the external application of heat, strychnin hypodermically, normal saline solution by the rectum or subcutaneously, and nutritive enemata. No food is given by the mouth for four or five days.

80.—See abstract in THE JOURNAL, ¶24, p. 534.

85. **Mastoiditis.**—The question of when to operate in mastoiditis is discussed by Phillips, who thinks that when symptoms of mastoid suppuration become apparent, we are face to face with the necessity of decision on this point. The very early symptoms may be, and sometimes are, relieved by other measures than external operation, such as free incision of the drum membrane, which will frequently relieve all indications of mastoid involvement. The whole theory of relief is based on the importance of free drainage and further involvement of the mastoid cells is checked by this in some cases, together with local blood-letting, the ice coil and poultices. During the early stages of middle ear suppuration, and even after mastoid symptoms appear, irrigation with hot sterile water is good treatment, but the tendency is to carry all these measures too far. He does not use the ice coil longer than twenty-four or thirty-six hours and poulticing would be almost as bad. The external operation should be performed when permanent remission of symptoms has not been obtained by complete drainage through treatment or application of ice coil or local blood-letting, when there should be absolutely no delay. Most hospital cases reach this point before they are seen and the utility of the mild measures is past. By still further delay complications may arise that make the operation more extensive and may even endanger life. In chronic otorrhea external operation may be required to overcome suppurative processes. This is especially so in cases with chronic otorrheic discharge and attempts should be made to cure all these cases permanently.

British Medical Journal, August 17.

Enteric Fever: Its Natural History, Modes of Dissemination and Prophylaxis. A. C. HOUSTON.—In opening the discussion Houston remarks that he was struck by three things: 1. The inability of medical science to stamp out a disease, which is still classed as preventable. 2. The failure in this direction in South Africa. 3. The notable discoveries that have been made in connection with its bacteriology in the last few years. He considers the agglutinative phenomenon as one of the most remarkable bacteriologic discoveries, though he points out its exceptions. He gives a tabulated statement of the points of differentiation between bacillus coli and bacillus typhosus. Nevertheless, it cannot be said that we have yet been able to isolate the bacillus typhosus from sewage and water supply. He asks whether there may not be some direct race of coli-like microbes having specialized properties and infectious qualities, but to consider them an agent in the propagation of the disease seems to him unsupported by present evidence. The water-borne nature of typhoid is an established fact, as is also the action of milk. He calls attention to the recent discoveries in regard to the danger of shellfish taken from sewage-polluted water. The question of soil in relation to typhoid fever is one requiring much caution, though he mentions that it is well to preserve an open mind on the question. The action of flood water, sewer gas, ground air, and ground water are also noted, and sewage, as it is a dangerous source of pollution. We must see that our water supplies are free from the bacilli of the colon group. The vitality of the typhoid germ in water is a matter in regard to which there is still much difference of opinion, but that some continue to exist for a long time seems to be indicated by Klein's results. The danger of dust is noted and also the fact of the bacillus typhosus escaping destruction under modern methods of sewage treatment, in which the author's own conclusions are somewhat different from those of the majority. He thinks it would be wise to regard the effluents from bacterial beds as still unsafe. Other points mentioned by Houston are typhoid bacilluria, and the action of urotropin on it, and recent evidences of infection through fried fish and laundry machinery. He mentions protective inoculation with Wright's vaccin, which he believes may be of use. The Widal reaction in relation to early diagnosis is too little employed by the profession. He then considered the sterilization of drinking water and filtration, and, as regards this last, believes that the sand filter only lessens the danger, and that small filters, with the exception of the Pasteur-Chamberland and, to a less degree, the Berkefeld, are only to be relied upon. The general measures which should be followed to-day are: To protect the water-supply and food from contamination; to be sure that drains and sewers are in good order, and to disinfect the stools and urine of enteric patients. Recent discoveries have shown us how manifold are the channels of infection, and how prolonged and serious the capacity of enteric fever patients to disseminate the disease may be. Recognition of the dangerous condition known as typhoid bacilluria and the value of urotropin as a remedy have a most important influence in the future in the control of the spread of the disease.

Vital Statistics of Enteric Fever. F. A. Dixey.—The summary of Dixey's article is given as follows: "1. The death rate from enteric fever in London is a fluctuating one, but has on the whole materially diminished, the most marked descent having occurred about sixteen years ago. 2. The seasonal relations of enteric fever remain fairly constant from year to year, but there seems to be a tendency, at least in years of low general prevalence, towards a progressive flattening of the autumnal maximum. 3. A comparison between London and New York in respect of their climate and enteric death rate, indicates that some meteorological conditions, especially perhaps temperature, are factors in the activity of the enteric infection. The relation, however, is not of such a kind as to make itself apparent from year to year in one given locality. 4. It is probable that the diminution in the death rate of enteric fever is really somewhat greater than it appears to be, from the inclusion in former times of enteric cases under other heads, notably typhus and simple continued fever. This source of error, however, was never very important, and is now practically non-existent. 5. The case-mortality of enteric fever is almost stationary, and seems likely for the present to remain so."

Neutral Red in the Routine Bacteriological Examination of Water. William G. Savage.—This author finds neutral red a very valuable agent for the differentiation of the bacillus coli and gives the results of a number of experiments made by him as showing this fact: "1. That a positive reaction obtained as described, while not certainly diagnostic of bacillus coli, yet in the vast majority of cases pointed to the presence of that organism. 2. That a negative reaction renders the presence of bacillus coli highly improbable. 3. That the test is very readily applied, and with reasonable care, fallacies in its employment can be avoided. 4. That it is a test which is of great value in the routine examination of water."

The Fallacy of the Permanganate Disinfection of Wells (Hankin's Method). M. L. Dhingra.—The author thinks Hankin's method of permanganate disinfection is of but little value. Potassium permanganate can only act under certain conditions, and even then is not continuous in action. It must first expend itself in oxidizing nitrites and organic matter before attacking the organisms, which are so resistant that it is applicable only in concentrated 5 per cent. solutions. For practical purposes it can be regarded only as a deodorant. The method is impossible in its practical application. The use of a couple of ounces of potassium permanganate does not bring about any profound changes in the chemical or biological constituents of well water.

The Lancet, August 17.

The Diagnosis and Surgical Treatment of Carcinomatous Stricture of the Colon. W. J. Walsham.—According to Walsham, the common form of carcinoma of the colon, viz., columnar-celled—is one of comparative benignity and may, for a considerable time, remain a purely local disease, the patient enjoying several years of comparative comfort before secondary deposits in the glands and internal viscera terminate his life. When, as is often the case, symptoms of acute obstruction have come on before surgical aid is sought, it is better to operate in two stages: 1. To do a primary colotomy with or without the withdrawal of the carcinoma on to the abdominal parietes. 2. When the patient has thoroughly recovered from the deleterious effects of obstruction, to remove the carcinomatous portion of the bowel and unite the ends above and below. There may be even almost complete stenosis and still no dissemination, but when dissemination at length occurs, with such symptoms as uneasiness, distension, eructations, and a series of conditions often attributed to indigestion, attacks of pain or spasm attributed to the colon independent of the time of taking food, liquid stools without any formed motions, constant progressive loss of weight and a constant desire to defecate, it is well to make an exploratory incision. If acute obstruction has supervened the safest course is to open the colon above the growth and to deal with the latter after the acute stage has subsided.

Annales de Dermatologie (Paris), July.

Treatment of Rodent Ulcer. Carle.—The slowly developing ulceration, with no propagation to the ganglia and no effect on the general health, is frequently misunderstood, as no one thinks of the possibility of rodent ulcer. Carle describes three cases of six, eight and eighteen years' duration respectively—each erroneously diagnosed and treated as lupus or syphilis. Complete extirpation is indicated when possible, but if the ulceration has extensively invaded the face, as was the case in two of his patients, curetting and cauterization will cure after the possible failure of skin grafting and cauterization with potassium chlorate. With or without anesthesia or cocain, the entire ulcerating surface is thoroughly curetted. Hemorrhage was considerable in one case but was arrested by tamponing. A gauze pad was then applied, impregnated with a mixture of 1 gm. arsenious acid in 75 gm. each of alcohol and water. The gauze was removed the fourth or fifth day and the area painted with a stronger mixture, increasing the strength to one part of the acid in forty parts each of water and alcohol, and leaving the affected part open to the air. No permanent dressings were applied and the eye was protected merely by a bandage. In two and one-half months the ulcer was covered with a good quality of epidermis and only a slight redness now marks the spot.

Kerosene Frictions for Alopecia Areata. Hallopeau.—A young woman who had had rebellious alopecia for more than a year, was practically cured by washing the head twice a day with soap and then rubbing kerosene vigorously into the bald patches. They soon became covered with soft hairs which by the end of eight months, had almost all been transformed into adult hairs.

Compression as a Means of Treating Ichthyosis. Hallopeau.—In a severe case of congenital ichthyosis described, the skin under the garters worn by the patient was normal. This suggested that compression might have some influence on the affection, and a bandage was applied to one arm to test this assumption. In a few days all the concretions under the bandage had disappeared. This fact suggests a new line of treatment for ichthyosis, and also indicates that the interference with the nutritional processes in this affection is not so severe as hitherto supposed.

Annales de la Soc. Med.-Chir. de Liege, June.

Practical Diagnosis by Microbian Antibodies. E. Malvoz.—The presence of pathogenic microbes does not necessarily indicate that the bearer is infected by them. But if the organic fluids contain the specific antibodies—showing that they must have been elaborated as a means of defense against the pathogenic action of the microbes in question—there is no longer any doubt that the organism has been invaded by these microbes. The properties of the humors—the consequences of the reaction of the organism in defense and in immunization—testify much more certainly to the existence of infection than the discovery of the pathogenic microbes on the mucous membranes. This defensive reaction is revealed by the elaboration in certain cells of the organism of special substances whose nature is still a mystery, but which we term antibodies. These pass from the cells into the organic fluids or at least into the blood serum. They induce the specific agglutination, precipitation, bacteriolysis or globulysis, and hence have been called by various writers according to the special process under consideration, agglutinins, precipitins, antidiastases, antitoxins, etc. Their action, it has been proved, depends on the combination of the alexin, which is found normally in the blood, and the specific between-body or *sensibilisatrice.* The presence of these antibodies in the serum is the best possible evidence that the organism has been invaded by the specific microbe, that a reaction has occurred, in short, that it is having or has had the disease. The alexin does not seem to differ in various species, but the *sensibilisatrice* is specific for each. The new method of diagnosis is based on the corpuscle-destroying property of the alexin in serum rendered globulytic beforehand. If a serum containing a specific *sensibilisatrice* is added to an emulsion of the microbes in question, the *sensibilisatrice* clings to the microbes and filters out of the fluid with them. The microbes thus *sensibilized,* acquire an affinity for alexin, and when added to normal serum, take up or bind the alexin in it in the same way. But if the microbes have not been previously submitted to the action of a *sensibilisatrice,* the alexin is unaffected by them. Consequently, for diagnostic purposes, all that is necessary is to determine whether the alexin in a given specimen of serum is free or whether it has been bound by the microbes. This is easily determined by adding to the specimen of serum some red corpuscles in blood previously *sensibilized* by an antibody. If the reds are destroyed, this hemolysis or globulysis, as it is called, is the proof that the alexin is intact, and hence, it demonstrates the absence of the specific *sensibilisatrice* in the serum. Malvoz finds the serum of rabbits, rendered hemolytic for hens' blood, most convenient for this new method of diagnosis. Defibrinated hens' blood is injected into the rabbits several times in succession. The serum of the rabbits then acquires the property of destroying the red corpuscles in hens' blood by the action of the alexin contained in it. The process is visible to the naked eye from the diffusion of the red color through the fluid as the reds are destroyed. The alexin is destroyed by a temperature of 55 C., consequently the rabbit serum lost its hemolytic property if heated to this point, but the *sensibilisatrice* is not affected by the heat. Tests with animals inoculated with blastomycetes, established the presence of a *sensibilisatrice* in their blood every time, but tests of persons with cancer failed to disclose any *sensibilisatrice* in their case. This is an argument against the causal relation of the blastomycetes to malignant disease. The serum from the rabbits inoculated with the blastomycetes was heated to 55 C. and added to an emulsion of the microbes after mixing with a little normal rabbit serum, containing the normal amount of alexin. The microbes—blastomycetes in this case—absorb the alexin in case they have been previously *sensibilized* by the specific antibody, and when hens' blood is added to the mixture, the red corpuscles remain intact, and no change ensues in the shape of the corpuscles or the color of the fluid. On the other hand, in case there is no *sensibilisatrice* for blastomycetes in the serum, the corpuscles are speedily destroyed. Lambotte by tests on these principles has demonstrated the identity of the bacillus alvei with the bacillus mesentericus, which he has long maintained, but which he was unable to prove until provided with this new method of diagnosing the specific reaction of the organism to a given pathogenic agent. [See Editorial in The Journal of June 29, p. 1832.]

Bulletin Medical (Paris), July 10.

Chyliform Effusion in the Pleura. F. Barjon.—A chyliform effusion usually commences insidiously, with little or no fever, and the patient is generally lost sight of before the cure is complete. Only 13 cases of chyliform effusion were found in a recent collection of 49 cases of milky effusion in the thorax. It is characterized by the long latency, the chronic course and the large amount of fluid, rich in fat, with no glucose. A personal case is described. As the patient reacted positively to the tuberculin test and as animals inoculated with the fluid exhibited evidences of tuberculosis, Barjon is convinced that the chyliform effusion is the manifestation of a chronic infection of the pleura, determined by an attenuated bacillary infection—by the tubercle bacillus in the case related.

Nord Medical (Lille), August 1.

Cold Rectal Injections in Typhoid Fever. Lemoine.—When for any reason it is impossible to apply cold baths in the treatment of typhoid fever, Lemoine finds that cold rectal injections are an efficient substitute. The water should be boiled and cooled to 18 or 20 C. and should be injected every two or three hours, the receptacle for the water being not more than 50 cm. above the plane of the bed. The canula should be inserted for 20 cm. and about 2 liters of water injected, very slowly, interrupting the flow from time to time so as not to distend the intestine too much. In the 32 cases in which this technique was followed, the temperature was reduced more rapidly than with the baths, but the effect was less durable. The temperature drops to the lowest point in twenty to thirty minutes after the injection. but in another half hour rises to what it was before the injection. Notwithstanding the insufficiency of the effect, the cold injections, as a rule, seem to ensure a lower temperature on the whole than the baths. The oscillations are less pronounced and the disease seems to run a more regular course. This fact he explains by the disinfectant action of the fluid as it washes out the intestine. He therefore recommends these injections, as far preferable to cold packs or applications which fatigue without really benefiting the patient. Delirium is exceptional in patients thus treated.

Presse Medicale (Paris), July 10.

Experimental Research on Smallpox. H. Roger and E. Weill.—Rabbits inoculated with pus from a smallpox patient resisted the disease or survived much longer than the control animals, when they were fed on exceptionally nourishing food. Other animals fed with ordinary food rapidly succumbed to the disease. Applying these results to man, smallpox patients were given eggs, soups, etc., even during the febrile period, and the results have surpassed anticipations. Experience has also shown that cases in which the patients refused this abundant nourishment, from lack of appetite or difficulty in swallowing, prove unusually severe with a grave prognosis. The smallpox produced in rabbits resembles more the disease as it appears in the new-born than in adults. In Roger's experience infants born to mothers in the course of smallpox, almost invariably die. Some die with a slow septicemia, hypothermia and emaciation, with no eruption. Others with these symptoms have a slight eruption characterized by small papules which dry up without suppuration. Others still may present the clinical picture of smallpox as it appears in adults.

Deutsche Med. Wochenschrift (Leipsic), August 15.

Diagnosis of Pharyngo-Esophageal Diverticulum. H. Schmilinsky.—A patient with recent pulmonary tuberculosis presented symptoms suggesting an aneurysm of the aorta, but radiography was negative. The difficulty in swallowing and the return of ingested fluids into the mouth, accompanied by mucus, indicated a diverticulum in the esophagus. Mucus was constantly rising into the mouth, especially when the patient bent forward, and pain was frequently experienced in the neck. The autopsy disclosed a typical pharyngo-esophageal diverticulum. In a similar case in a woman of 72, the symptoms had been noisy eructations, without vomiting or regurgitation of food. After a year she noticed that mucus came up into her mouth with the eructations; six months later food seemed to stick in her throat, mostly meat and bread, sometimes fluids. What she was unable to swallow returned, gurgling, into her mouth. Her chief annoyance, however, was the frequent rising of mucus into the mouth which disturbed her even in sleep. A sound introduced into the esophagus for 17 cm. encountered an obstacle. A rubber bag on the end of the sound could be inflated to the size of a pigeon's egg without discomfort, but could not be withdrawn, showing that it must be in a diverticulum with a narrow entrance. The esophagoscope confirmed the existence of a diverticulum, the entrance 14 cm. below. The Roentgen rays also showed a diverticulum very distinctly after the patient had swallowed a little bismuth. The bismuth deposits could be seen in the diverticulum and could be stirred up with a sound. As they probably caused the mouth of the sac to gape and admit air, the diverticulum itself cast a shadow on the screen.

Diagnosis of a Deep Diverticulum in the Esophagus. W. Zweig.—There are only seven cases on record of a diverticulum low down in the esophagus, but three have been observed recently at Boas' clinic. Improved diagnostic technique will probably render their discovery more frequent. Zweig introduces a tube with a funnel-shaped opening into the esophagus. It almost invariably passes into the diverticulum. A second similar tube is then introduced, and this always passes on into the stomach. The first tube is then filled with a solution of methylene blue, the amount calculated to correspond to the capacity of the diverticulum, previously determined by aspirating the contents. The tube in the stomach is then withdrawn, if the blue solution is held in an actual diverticulum, the stomach tube will show no traces of the stain, while if the disturbances have been caused by a mere dilatation of the esophagus, the stomach tube will be stained and will contain more or less of the blue fluid. Radiography after the patient has swallowed bismuth, confirms the diagnosis. In none of the three cases was there any vomiting of food from a previous day. Swallowing was painful in only one case. It was impossible to obtain any information from gastrodiaphany. Attempted inflation of the stomach with carbonic acid caused the inflation of the diverticulum alone in two cases, with intense oppression and expulsion of foam. Zweig recently had a case of dilatation of the esophagus under observation. The food ingested seemed to stop just above the stomach where it remained until the man drank water, when it all slipped at once into the stomach. This phenomenon had been noted for twenty-seven years and had never caused any other disturbance. He is now 63 years old. He was run over by a carriage and had a rib fractured in 1863. The two-tube test disclosed a moderate dilatation of the esophagus 44.5 cm. below the teeth.

Mitteilungen a. d. Grenzgebiete (Jena), vii, 3.

Thyroidism in Case of Simple Goiter. J. von Mikulicz.—The functions of the thyroid gland are not necessarily disturbed in every case of simple goiter. Such disturbances are rather the exception than the rule. In 117 cases of uncomplicated goiter, 48 showed no other symptoms or merely symptoms of compression of adjacent organs, especially the trachea. In 69 there were nervous symptoms indicating hyperfunction of the thyroid gland, with or without indications of compression. Study of these various cases shows that a moderate degree of tachycardia—112 the maximum—must be included in the symptom-complex of a goiter unaccompanied by dyspnea or alterations in the heart and not complicated by Basedow's disease. There is no exopthalmus, but nervous symptoms were noted in nearly all of the last group of 69 patients: two symptoms in 9; three in 13; four in 8; five in 2 and six in 2. In the last 2 cases the entire picture of restlessness, subjective palpitation, angina pectoris and tremor of hands and tongue, coexisted with headache and vertigo. Tremor was the most frequent symptom and headache next. The clinical picture of the simple goiter in his cases, therefore, included a moderate amount of tachycardia, certain nervous symptoms, alone or in combination, and slight suggestions of the ocular symptoms of Basedow's disease in a few instances. He calls this the syndrome of spontaneous thyroidism. Basedow's disease, therefore, can not be explained by hyperfunction of the thyroid gland alone. The goiter, however, is an important factor, whether we attribute the disease to a primary neurosis or to any other kind of autointoxication. The thyroid gland in the circulation of the subject of Basedow's disease acts like a multiplier. The goiter is not a primary, but merely one of the co-ordinated symptoms of the disease. The thyroid gland becomes hypertrophied on the basis of the same influences which induce the manifold trophic disturbances in other organs and tissues. The hypertrophy of the gland impels it to excessive function, and thus the symptoms of spontaneous thyroidism are superposed, multiplying the entire clinical picture. Removal of the thyroid gland abolishes the multiplier, and renders recovery possible, either spontaneous or assisted by the usual internal measures. The failures to cure after extirpation of the gland are due to the severity of the original affection, which maintains the syndrome in spite of the removal of the multiplier. In the cases of Basedow's disease without a goiter, the primary disturbances are so severe that the typical clinical picture is produced without the aid of the multiplier.

Relations Between Erysipelas and the Streptococcus. P. Klemm.—The streptococcus induces serous inflammation as the principal effect of its action. Its pyogenic and necrotizing properties are only secondary and are not manifested except under certain conditions. The streptococci usually find their way into the circulation through the lymphatic apparatus of the throat, especially through the tonsils. Swelling of the joints, etc., in follicular tonsillitis, scarlet fever, etc., is determined by a serous or sero-fibrinous transudation into the cavity of the joint without destruction of tissue. Complete restitution is the rule, while a staphylococcus infection destroys the tissues and forbids anatomic and functional restitution. Notwithstanding the apparent differences between a simple surface erysipelas and an intramuscular streptococcus phlegmon, both processes are absolutely alike, and the difference between them is merely the mechanical conditions of the tissues involved. Klemm therefore considers erysipelas a rapidly spreading serous lymphangitis, located either above or below the fascia, and with the streptococcus as the causal agent. He is convinced that infection occurs by contact, as he never succeeded in inducing it or in developing cultures of the streptococcus from the air. The practical benefit of his researches is that he has succeeded in banishing erysipelas from his hospital. All patients with suppurating streptococcus affections, such as otitis media, follicular tonsillitis, etc., are liable to transmit the streptococcus infection to others whose skins or throats are in a specially receptive condition. New patients are examined for streptococci and if they are discovered, the patients are put in a special streptococcus ward with separate attendants. Especial attention is paid to tuberculous fistulæ which are liable to become infected with streptococci at any moment. Every precaution is taken to reduce the chances of infection to the minimum. Dressings are cut off instead of being unwound, and are placed at once in disinfecting fluid. He is inclined to believe that an already existing streptococcus mycosis renders the body more resistant to a second infection, as not a single case of erysipelas has developed, even in the streptococcus wards since these measures have been adopted.

Functional Results After Operations on the Stomach. R. Rencki.—Seventeen cases in which operations were performed on the stomach for the cure of round ulcer or benign stenosis of the pylorus, have been followed to date. The cure has been complete and permanent in all those cases in which the chemistry of the stomach has returned to normal. All the patients have been wonderfully relieved and improved, but a few with persisting hyperchlorhydria complain of heartburn and oppression in the stomach, and a small number exhibit symptoms of a recurrence of the ulcer. The fate of a round ulcer depends on the chemistry of the stomach. As long as there is excessive secretion of HCl we can not be sure that the ulcer has healed over or that another may not recur, as in one of the cases reported. Hyperchlorhydria is the cause of the round ulcer, and it should never be neglected, for fear of this termination. In all other respects the functional results of the gastro-enterostomy have been satisfactory from every point of view.

Muenchener Med. Wochenschrift, August 13.

Diagnosis of Malignant Tumors. E. Leser.—Out of 392 patients operated on for malignant tumors in the last eleven years, 305 have been traced to date and 78 found in good health. They include 9 cases of carcinoma of the face, 16 of the breast, 29 of the alimentary canal, 3 of the testicles and 2 of the kidneys. None of the patients with carcinoma of the tongue or esophagus is still alive. The operation was performed over ten years ago in 7 cases; over six years in 25, and over three years in 29. The diagnosis of a carcinoma of the stomach or intestines is usually only presumptive, as there are no typical symptoms. The insignificant, invisible hemorrhages recently described by Boas (see The Journal, June 8, p. 1670), may prove of valuable assistance. Alternation between diarrhea and constipation is important and should suggest malignant disease in a patient between 35 and 50; and the feces should be carefully examined with the microscope. Digital examination in profound narcosis should never be neglected. In all cases an exploratory laparotomy should be done on the mere suspicion of carcinoma. When the diagnosis becomes positive, the patient is already doomed. Leser operates, therefore, at the earliest moment and does not refuse to operate even in advanced stages, as the patient's condition is rendered so much more tolerable. He adds that 14 of his 42 patients operated on for carcinoma of the rectum, are still alive, several more than seven or eight years after the operation. A number had been operated on elsewhere previously for one to three recurrences. The lymph glands in the vicinity—even those apparently sound—should be extirpated with the neoplasm and the connecting routes and connecting tissue. The cosmetic effect is less satisfactory, but the curative results are far better. He removes the entire lip and says that the entire tongue must be ablated in case of a carcinomatous growth—partial operations are insufficient. Nature compensates the absent tongue by drawing up the tissues beneath and down from the cheek until almost a new tongue results. Sharp instruments should be used as little as possible; the neoplasm should be enucleated with the fingers, aided by the closed scissors, remembering that the tendency to spread is always in the direction of least resistance. Leser ascribes his successful results to his strict enforcement of the orders that each patient must return for examination regularly, at first every eight to ten weeks, no matter how well he feels. This is the only way to forestall recurrences. He has one patient in permanent robust health after five operations for recurring carcinoma, and others after three operations. Recurrences require prompt operating and no one but the physician is able to detect their approach.

Atropin Treatment of Ileus. Gebele.—If an internal remedy is indicated in case of ileus, especially in ileus from paralysis, *morphin* is much to be preferred to atropin. In all other cases, surgical intervention is the only treatment. But in all cases of ileus benefit may be derived from lavage of the stomach and injection of several liters of oil, with, possibly, 70 to 100 gm. olive oil internally, repeated several times a day. An exploratory laparotomy is much to be preferred to the administration of atropin which masks the symptoms and allows the favorable moment for intervention to pass, as occurred in a fatal case reported.

Syphilitic Sciatica. A. Biewerth.—Mendel has recently described three cases of syphilitic sciatica and Niewerth has had occasion to treat another. All were promptly cured by mercurial treatment after the usual remedies, including potassium iodid, had demonstrated their inefficacy. Vapor baths caused violent exacerbations of the pains in one case, suggesting the existence of an acute inflammatory process.

Application of the Stomach Sound in Case of Ulcer. W. Flade.—The information that can be derived in regard to ulcer of the stomach from introduction of the stomach sound or even from artificial inflation of the stomach with air or carbonic acid, is not very important. On the other hand, the procedure is by no means so harmless as generally accepted. The danger of perforation is particularly great in case of young women, and is especially imminent when the ulcer is located in the anterior wall. Severe hemorrhage seldom results, but the injury caused by the sound may entail the imperceptible hemorrhages to which Boas has called attention. The use of the stomach sound should be absolutely rejected in case of an established ulcer, and also in many other gastric affections in which it is now currently used. The writer is a specialist for gastro-intestinal affections and speaks from a wide experience.

Therapeutische Monatshefte (Berlin), July.

Treatment of Cutaneous Affections With Cold. E. Saalfeld.—Very favorable results are reported in this communication from the application of liquefied air, ethyl chlorid or a mixture of the latter with methyl chlorid. Saalfeld asserts that the prompt improvement and the convenience of this method of treatment commend it for all chronic cutaneous affections, with much infiltration, and in which it may be anticipated that resorption will follow an acute, artificially induced inflammation.

Symptomatic Treatment of Cough. M. Saenger.—One of the best measures for relieving a cough is the inhalation of the vapors of menthol. Saenger says that an inexpensive and very effective method of inhaling is to warm a few crystals of menthol in a spoon over a candle for five to twenty seconds and then inhale the fumes, repeating as often as necessary. A simpler way, perhaps, is to pour ten to twenty drops of a 50 per cent. alcoholic solution of menthol on the palms and then hold them, like a mask, over the face. In case of excessive mucous secretions in the throat, he recommends injecting 1 or 2 gm. of a 10 to 20 per cent. solution of menthol in olive oil, directly into the throat. Violent coughing is induced which expels all the old accumulations of mucus, and enough of the menthol is retained to accomplish the purpose of an inhalation. This measure in chronic bronchitis or phthisis will arrest the cough for one to five hours after the first paroxysm is past, or even longer, if supplemented by inhaling as above described. It has a cumulative action and the intervals should gradually be lengthened. These injections have proved extremely effective in whooping cough. Hemorrhage is a contra-indication. [A writer in the *Bull. Med.* has recently suggested that the simplest method of inhaling menthol is to chew a crystal and then breathe through the mouth. Ed.]

Wiener Klin. Rundschau, August 11.

Case of Poisoning With Nitrobenzol. V. Simerka.—As *nitrobenzol* is not dissolved by water or the stomach secretions, it remains unchanged for an interval—usually about half an hour—after its ingestion. Consequently, thorough lavage of the stomach is indicated until the fluid aspirated is odorless. Alcohol and oils dissolve it and all substances containing them, such as milk, wine, etc., should be avoided. The fatal cases on record were not treated with lavage. In two of the published cases the symptoms of intoxication were apparent at once. The only constant symptoms are the odor of the breath and the cyanosis. The blood becomes brownish and the entire central nervous system is more or less affected, with various manifestations. The dose in the fatal cases was 150, 20 or 15 gm. Serious intoxication has followed ingestion of three drops and recovery has followed ingestion of as much as 30 gm.

Wiener Med. Blaetter, July 4 and 11.

Atropin in the Differentiation of Bradycardia. A. Johanessen.—Bradycardia may be caused by a direct or reflex irritation of the bulbar vagus center, or by some lesion of the automatic motor center of the heart in the myocardium. These primary causes can be readily differentiated by the subcutaneous injection of 1 mg. of atropin. In case the bradycardia is of intracardial origin, it continues unaffected by the action of the atropin. But if it is due to irritation of the vagus center, it is arrested by the atropin, as the latter paralyzes the heart-retarding apparatus—the terminals of the vagus in the heart. Several cases are described, with postmortem discovery of sclerosis of a coronary artery in the cases in which the bradycardia persisted uninfluenced by the atropin. In the case in which the bradycardia was arrested by the atropin and the pulse increased at once from 45 to 110, fresh thrombosis was found in the left middle cerebral artery with softening of a portion of the internal capsule, the optic thalamus, etc. The heart was intact.

Ztft. f. Orthopaedische Chirurgie (Stuttgart), ix, 2.

Operative Treatment of Congenital Luxation of the Hip-Joint. A. Codivilla.—In cases in which the parts offer an obstacle to the reposition of the head of the femur, Codivilla levers the latter into place by an instrument shaped like a narrow, concave spade with a hook at the tip. It is inserted under the muscles and the capsular ligament until the hook fits over the anterior inferior spine, which affords it a solid support. The handle is then pushed downward, while the lower end of the femur is swung around to meet it. The combined leverage of the spade and of the lower end of the femur forces the head in the concavity of the spade, along into its normal position. If the complete absence of the acetabulum is the cause of the luxation, he remedies this by an extra-articular operation, detaching the capsule and taking a tuck in it, with freshening of the periosteum and ilium. If an incision in the capsule is necessary, he uses an instrument similar to König's mouth-opener to tear the capsular isthmus, supplementing it with the lever above described. The head of the femur must be left covered with its capsule, which will reduce the danger of ankylosis. The hip-joint should be opened up through an incision along the anterior margin of the tensor fasciæ latæ, continued upward along the iliac crest. The tensor fasciæ latæ and a portion of the gluteus minimus and medius is then detached from the ilium.

Gazzetta degli Ospedali (Milan).

Antituberculosis Serum in 1900-1901. Maragliano.—The Journal has published from year to year Maragliano's reports of the results of treatment of tuberculous patients with his antitoxin. In the year closed in June, 130 out-patients were treated; 36 were clinically cured, including 17 with fever and destructive processes—with a cavity in 3; 58 were improved and the disease remained stationary in 31. In the remaining 5 the disease progressed. None of the advanced cases treated in the institute was cured. It is impossible for the antitoxin to cure without the assistance,—the re-enforcement of the organism. When the latter is unable to afford this assistance, the antitoxin is comparatively powerless. It is also unable to cope with the toxins from micro-organisms other than the tubercle bacillus. Maragliano has always maintained that tuberculosis is essentially a toxicosis—that the tubercle bacillus is harmful on account of the toxins it produces.

August 4.

Pathogenesis of the Disturbances From Helminthiasis. G. G. Battista.—Four cases are described showing the various disturbances to which children with helminths are liable. In one, an acute intestinal catarrh with typhoid symptoms was accompanied by a diffuse bronchitis and was followed by death in twenty-nine days. In another, the only symptom was croup. After death from suffocation, an ascaris was found in the larynx and a bunch in the esophagus. Another child suffered from frequent, sudden bronchial attacks with fever, all symptoms vanishing after expulsion of a few ascarides. In another child a pneumonia, accompanied by fever and abdominal pains, rapidly subsided after expulsion of a few ascarides. The irritating action of the parasites in the intestines had probably irritated the peripheral fibers of the vagus and induced the bronchial spasms in these and other cases, or the relaxation of the pulmonary vessels in a bronchial catarrh or actual asthma. The irritation may be in the respiratory organs or in the respiratory center. There may be at the same time an intestinal autointoxication, induced by the mechanical action of the parasites, which may influence the vasomotor center or the local ganglia, inducing the angioneurotic disturbances. These assumptions would explain the epidemics of febrile asthma described by Bellotti, and the bronchial asthma from gastrointestinal autointoxication mentioned by De Dominicis, and also the development of pneumococcus infection from pneumococci vegetating harmlessly in the lungs until their latent activity is aroused by some—possibly slight—thermic, chemical or mechanical alteration in the tissues on which they are lying. The reflex irritating action of helminths in the intestines on the innervation of the pulmonary vessels, is similar to the effect of an external trauma on the thorax or the trauma of a surgical operation, which induces vasomotor disturbances and thus prepares the soil for the development of hitherto harmless pneumococci in the lungs.

Absorption by the Large Intestine. G. Barbiana.—The large intestine has great absorbing power although less rapid than the stomach. Potassium iodid appears in the urine twenty minutes after injection into the large intestine, salol in forty-five, quinin in fifty, and chloroform and ether in sixty minutes. The influence of chloral is felt in ten minutes and apomorphin in four. The minimal fatal dose of a poison injected into the large intestine in animals kills them exactly as it does when taken by the mouth. Absorption is most rapid near the ileo-cecal valve and least rapid in the middle portion. The absorbing power can be increased by the mechanical action of water or by the chemical action of sodium sulphate. The latter stimulates the mucosa to increased function. The intestine does not absorb alimentary substances as well as it absorbs medicine. Even predigested foods are not absorbed in sufficient amounts to supply the needs of the organism except temporarily. The details of this research are given in the *Policlinico*, viii, C.

August 11.

Safe Limit in Operating on Veins. D. Taddei.—Continuing his experimental research on suturing and lateral ligature of veins, Taddei considers himself justified in proclaiming that the amount of constriction which the veins will bear depends on their distance from the heart. It is possible to reduce the caliber of a vein by one-half, without ill results, if the vein is straight and not far distant from the center of circulation. But if at a distance, and if the conditions are unfavorable, as in the case of the femoral vein for example, the lumen is liable to become obliterated by a thrombus.

Iodipin Test of Gastric Motility. Schupfer has been experimenting with the iodipin test of the motor function of the stomach in Baccelli's medical clinic. He is impressed with its simplicity, facility and the general reliability of its results. He warns that icterus is a contra-indication, even for several days after the icterus has disappeared. By combining the iodipin and the salol tests it is possible in some cases to determine from the results obtained the permeability of the pancreatic duct.

The Public Service.

Army Changes.

Movements of Army Medical Officers under orders from the Adjutant-General's Office, Washington, D. C., Aug. 15 to 21, 1901, inclusive:

Earl S. Bullock, contract surgeon, leave of absence granted.

William H. Corbusier, major and surgeon, U. S. A., member of a retiring board convened at Governor's Island, N. Y.

G. Parker Dillon, contract surgeon, from Jefferson Barracks, Mo., to San Francisco, Cal., en route for service in the Division of the Philippines.

Charles R. Greenleaf, colonel, asst. surgeon-general, is detailed to represent the Superior Board of Health of the Philippine Islands at the meeting of the American Public Health Association, to be held in the city of Buffalo, N. Y., Sept. 16-20, 1901.

Alva R. Hull, contract surgeon, from San Francisco, Cal., to duty at Jefferson Barracks, Mo.

Richard W. Johnson, major and surgeon, U. S. A., member of a retiring board convened at Manila, P. I.

John S. Kulp, captain and asst.-surgeon, U. S. A., member of a board convened in New York City, N. Y., Sept. 24, 1901, to examine officers for detail to duty with the Ordnance Department.

Henry Lippincott, colonel, asst. surgeon-general, member of a retiring board convened at Governor's Island, N. Y.

Walter D. McCaw, major and surgeon, U. S. A., member of a retiring board at Manila, P. I.

Frederick H. Morhart, captain and asst.-surgeon, Vols., sick leave extended.

William E. Musgrave, contract surgeon, from San Francisco, Cal., to duty at the Army and Navy General Hospital, Hot Springs, Ark.

Louis A. Thompson, contract surgeon, leave of absence granted on account of sickness.

Edwin P. Tignor, contract dental surgeon, from Baltimore, Md., to duty at Fort Riley, Kan.

Allie W. Williams, lieutenant and asst.-surgeon, U. S. A., member of a board in New York City, N. Y., to examine officers for detail to duty with the Ordnance Department.

Robert N. Winn, lieutenant and asst.-surgeon, U. S. A., member of a board at Fort Riley, Kan., to examine officers for promotion.

Charles E. Woodruff, major and surgeon, U. S. A., member of a board at Fort Riley, Kan., to examine officers for promotion.

Appointments, Promotions, Retirements, Etc.,

Of Army Medical Officers recorded in the Adjutant-General's office, between July 15 and August 15, 1901. Previous notices of this character were published in THE JOURNAL of August 10, 1901. No appointment, promotion or other change in the status of medical officers of the Regular Army was recorded during the month. In the Volunteer Army the following were reported:

Appointments.—To be surgeon, with the rank of major: Ralph S. Porter, of Illinois; Robert Burns, of New Hampshire; Captain Vernon K. Earthman, asst.-surgeon. To be asst.-surgeons, with the rank of captain: George H. Calkins, of New York; W. Turner Wooten, of Maryland; Harry R. Lemon, of Illinois; Luther S. Harvey, of Florida; Michael A. Rebert, of Pennsylvania, and Henry du R. Phelan, of California.

Honorably Discharged.—Major Franklin A. Meacham, surgeon; Major Frank A. Artand, surgeon; Captain Thomas T. Jackson, asst.-surgeon; Captain Edwin P. Hayward, asst.-surgeon; Captain Compton Wilson, asst.-surgeon; and Captain Henry H. Rutherford, asst.-surgeon.

Commissions Vacated by New Appointments.—By Major Damaso T. Laine, appointment as major and surgeon, U. S. Vols. (act of Feb. 2, 1901): by Captain Vernon K. Earthman, asst.-surgeon, by appointment as major and surgeon, U. S. Vols.

Mustered Out of Service, Porto Rico Regiment.—Captain Jose Lugo-Vina, asst.-surgeon, and Lieutenant Simon Moret, Jr., asst.-surgeon.

Navy Changes.

Changes in the Medical Corps of the Navy, for week ending Aug. 24, 1901:

Asst.-Surgeon C. R. Burr, detached from the *Monongahela*, ordered home, granted leave of one month, and resignation accepted to take effect at the expiration of that period.

Medical Director T. J. Turner, retired, died at Mackinac Island, Mich., Aug. 20, 1901.

P. A. Surgeon D. H. Morgan, detached from Norfolk Hospital and ordered to the *Monongahela*, August 26.

P. A. Surgeon D. A. Carpenter, detached from the *Franklin* and ordered to the Norfolk Hospital.

Marine-Hospital Changes.

Official list of the changes of station and duties of commissioned and non-commissioned officers of the U. S. Marine-Hospital Service, for the seven days ended Aug. 22, 1901.

Surgeon H. R. Carter, granted leave of absence for fourteen days from Aug. 20, 1901. Leave of absence granted by Bureau letter of August 16 revoked.

P. A. Surgeon J. O. Cobb, granted ten days' extension of leave of absence.

P. A. Surgeon J. B. Stoner, granted leave of absence for seventeen days from September 2.

P. A. Surgeon G. B. Young granted eight days' extension of leave of absence from August 22.

Asst.-Surgeon L. D. Fricks, relieved from duty in the Philippine Islands, and directed to proceed to San Francisco, Cal., and await orders.

Asst.-Surgeon M. K. Gwyn, relieved from duty at Louisville, Ky., and directed to proceed to San Francisco Quarantine and report to the medical officer in command for temporary duty; thence to proceed to Manila, P. I., and report to the chief quarantine officer for duty.

Asst.-Surgeon T. D. Berry, relieved from duty at Cienfuegos, Cuba, and directed to proceed to Louisville, Ky., and report to the medical officer in command for duty and assignment to quarters.

Asst.-Surgeon Edward Francis, relieved from duty at the Immigration Depot, New York City, and directed to proceed to Washington, D. C., and report to the director of the Hygienic Laboratory for duty.

A. A. Surgeon W. R. Hicks, granted leave of absence for ten days from August 15.

Hospital Steward M. Walerius, granted leave of absence for seven days from August 1, under paragraph 181 of the regulations.

Hospital Steward R. F. Troxler, granted leave of absence for one month from August 20.

Hospital Steward J. E. Beck, granted leave of absence for three days from August 15, under paragraph 181 of the regulations.

Hospital Steward M. H. Watters, granted leave of absence for seventeen days from September 3.

BOARD CONVENED.

Board convened to meet in Philadelphia, Pa., Aug. 21, 1901, for the physical examination of an applicant for appointment as lieutenant in the Revenue Cutter Service. Detail for the Board: Surgeon H. W. Austin, chairman; Asst.-Surgeon J. S. Boggess, recorder.

Health Reports.

The following cases of smallpox, yellow fever, cholera and plague have been reported to the Surgeon-General, U. S. Marine-Hospital Service, during the week ended Aug. 24, 1901:

SMALLPOX—UNITED STATES AND INSULAR.

California: San Francisco, Aug. 8-11, 2 cases.
Georgia: Pickens County, July 1-Aug. 10, 37 cases.
Illinois: Chicago, Aug. 10-17, 1 case.
Massachusetts: Boston, Aug. 10-17, 2 cases.
Nebraska: Omaha, Aug. 3-10, 1 case.
New Jersey: Jersey City, Aug. 11-18, 1 death; Newark, Aug. 10-17, 4 cases.
New York: Elmira, Aug. 3-17, 4 cases; New York, Aug. 10-17, 36 cases.
Pennsylvania: Aug. 10-17, Philadelphia, 6 cases, 1 death; Pittsburg, 2 cases.
Utah: Salt Lake City, Aug. 10-17, 4 cases.
Washington: Tacoma, Aug. 4-11, 1 case.
Philippines: Manila, June 22-July 6, 1 case.

SMALLPOX—FOREIGN.

Austria: Prague, July 27-Aug. 3, 1 case.
Belgium: Antwerp, July 27-Aug. 3, 1 death.
Colombia: Panama, Aug. 5-12, 7 cases.
France: Paris, July 27-Aug. 3, 8 deaths.
Great Britain: Glasgow, Aug. 2-9, 2 cases: Liverpool, July 27-Aug. 3, 1 case; London, July 27-Aug. 13, 1 death.
India: Bombay, July 16-23, 2 cases, 2 deaths; Calcutta, July 13-20, 6 deaths; Karachi, July 14-21, 1 case, 1 death; Madras, July 6-19, 16 deaths.
Italy: Messina, July 27-Aug. 3, 11 cases, 4 deaths.
Mexico: Mexico, Aug. 4-11, 1 case.
Russia: Moscow, July 22-27, 5 cases, 1 death; St. Petersburg, July 13-27, 3 cases.

YELLOW FEVER.

Colombia: Bocas del Toro, Aug. 6, 1 case; total cases to date, 8.
Costa Rica: Port Limon, Aug. 3-10, 4 cases, 2 deaths.
Cuba: Regla, Aug. 7, 1 case: San Antonio de los Banos, Aug. 8, 1 case.
Mexico: Vera Cruz, Aug. 3-10, 2 cases, 1 death.

CHOLERA.

India: Bombay, July 16-23, 10 deaths; Calcutta, July 13-20, 23 deaths: Madras, July 6-19, 2 deaths.
Japan: Yokohama, July 13-20, 1 case, 1 death.
Java: Batavia, June 29-July 6, 33 cases, 23 deaths.

PLAGUE—FOREIGN AND INSULAR.

Australia: Brisbane, March 1-April 30, 15 cases, 3 deaths.
India: Bombay, July 16-23, 107 deaths; Calcutta, July 16-20, 11 deaths; Karachi, July 14-21, 7 cases, 1 death.
Philippines: Cavite, July 6, 3 cases: Concepcion, July 6, 1 case; Malabon, July 6, 3 cases; Malolos, July 6, 6 cases; Manila, June 22-July 6, 43 cases, 18 deaths; Naic, July 6, 3 cases; Paranaque, July 6, 3 cases; Santa Rosa, July 6, 1 case.

THE NATURE OF THE CANCEROUS PROCESS.*

ROSWELL PARK, A.M., M.D.
Professor of Surgery, Medical Department, University of Buffalo.
BUFFALO, N. Y.

Like a huge and frowning sphinx at the very gateway or entrance to the field of surgical pathology has stood for centuries the great problem of the nature of cancer. This has, at least until recently, remained the inscrutable mystery of ages, although, like the great sphinx at Gheizeh, it has been always a target for shafts of all kinds. Almost every theory which the ingenuity of the human race could conceive has been advanced to account for the existence of cancer, while each theory has been ardently supported until proven unsatisfactory, or often much longer. To-day, while we desire always to pay due deference to the scholars and thinkers of times past, the only hypotheses which are even worth mentioning in this connection can be characterized as the dietetic, the embryologic, the irritation, and the parasitic theories. The dietetic theory is of importance only in case we may succeed in maintaining the parasitic nature of the disease, when it may become a subsidiary question as to whether certain raw or uncooked food may furnish at least some of the parasites in question. So far as can be seen, only to this extent can the matter of diet have anything to do with the nature of cancer. How far it may come into consideration in explaining rapidity of growth, or even susceptibility to infection, is another matter, also of subsidiary importance.

The embryologic theory of Cohnheim was a vast stride in advance, in that it offered the explanation of many curious and anomalous growths, some of which are included among the dermoids and the teratomata, while others are more distinct neoplasms of benign nature; but nothing contained within the hypothesis can ever explain the peculiar behavior of cells which constitutes the essential feature of malignant growths. Cohnheim's explanation is sufficient to account for the presence of certain cells in unusual localities, but not for their peculiar behavior. The relation of irritation and trauma to cancer formation has always attracted attention, and to-day figures perhaps as prominently as it ever did in this respect. That malignant growths frequently do follow local injuries and local irritations is most certain. The same thing is exactly as true of certain of the infectious granulomata, especially of tubercular lesions, and viewed in its proper aspect we must hold that, while serious injuries provoke extensive and serious reaction, minor injuries are often followed by such incomplete reaction and such altered tissue relations as to leave points of least resistance, which in tuberculosis, as in cancer, are favorite foci for infection. Granting the ubiquitousness of the infectious agent, and a point of lessened resistance, one may easily appreciate the relation of trauma to cancer. The same is true of that constant but trifling traumatism which we term local irritation, as, for instance, from a dirty pipe or a jagged tooth. In connection with such irritation, there must always be an abrasion of surface, and this abrasion always invites infection. Nevertheless, the relation between irritation or trauma and cancer is an indirect one, and, while accounting for certain predisposition, does not account for the active disease.

The parasitic or infectious theory of cancer is the only one which satisfies the needs of both the pathologist and of the clinician. There has always been a strange apathy among the clinicians who meet so often the antemortem features of this disease, but who apparently remain so aghast at its mysteries that they have been content to leave its solution to the microscopist. The histologists, on the other hand, have their only opportunity of studying the disease in dried and hardened sections beneath the lens. The view points of these respective gentlemen have been so widely different that they have rarely, if ever, gotten together and discussed the situation on common ground. All examinations of fresh and still warm specimens and all interpretation of the phenomena during life have been neglected in this too minute division of labor. It was the realization of all this that impelled me years ago to outline the character of the investigation required, and to secure from the Legislature of the State of New York the facilities for furthering it. In a paper published years ago,[1] I insisted that the disease must be studied by the pathologist, the biologist, the chemist, the histologist, and the clinician, all working in close association, and not at long range. In the Laboratory that was founded through the appropriation of the New York State Legislature, provision was made for associating all these specialists, and the result has been that very marked advance has been made in our knowledge of the disease. The man who knows the disease solely by what he has learned from deadhouse specimens is in poor position to explain its course, whereas the man who has simply watched the disease during life may have strong views about its infectious nature, which, however, he can justify by nothing more than by analogy, but the combination of clinical observation with experimental and laboratory work is sure to solve this problem, if it be not already solved, in a way as brilliant and as helpful as did similar researches reveal the mystery of tuberculosis.

---

* Read in the Symposium on the Surgical Aspect of Carcinoma, before the Section on Surgery and Anatomy, at the Fifty-second Annual Meeting of the American Medical Association.

[1] New York Medical Record.

To-day, you will with me hold this to be true, that the history of absolute failure during times past to demonstrate an intrinsic cause, combined with accurate clinical observation and constant contact with cases, with a study of the disease as it occasionally occurs in endemic form, with the arguments by analogy (upon which I shall elaborate in a moment), and with recent microscopic studies, all conspire to stamp the disease as due to an extrinsic cause, *i. e., to be parasitic in origin.* Thus far one may safely go without transgressing well-defined limits. Are we now able to go further and say that the parasites have been discovered? For myself, I do not hesitate to answer this positively in the affirmative; that is, I am firmly of this opinion, based upon work done elsewhere, and especially upon that done, to my own positive knowledge, in our own laboratory, and corroborated apparently by the independent investigations of Pfeiffer, Sawtschenko, Sjobring, Eisen, and most recently, of Max Schüler, whose new monograph just published is to me a striking, independent and beautifully satisfactory demonstration of every statement that has emanated from the Buffalo Laboratory.

The arguments that can be adduced in favor of the parasitic hypothesis can be summarized in brief space without consuming too much time. For this purpose, take first the argument by analogy, beginning with the lower forms of life. Tumors in trees and plants are well known to vegetable pathologists and botanists. They occur so often as to escape notice. They vary in size from the most trifling gall to those large woody masses known as *xylomata*, which bring about the eventual destruction of the tree. They are frequently spoken of as tree cancers. These are due almost invariably to a species of infection. In the case of the so-called galls, the infecting agent or parasite is some minute insect which disturbs cell growth and produces cell proliferation. In the oak genus alone, for instance, there are known over eighty varieties of nut galls produced in this way. In other instances the first injury is traumatism, or its equivalent, such as is produced by the freezing of water contained within the grooves of the bark and the consequent splitting open of this protective covering, with its possibility for infection of the growing wood beneath. Through this laceration infectious agents enter from without and produce similar results. When carried to the extreme, the nutrition of the limb, or of the entire trunk, may be so far disturbed as to determine the death of the whole, or a part, of the tree. Were parasitic agents entirely excluded there would be no such thing as cancer of trees. Could they be excluded, every laceration of bark would heal, as does any protected wound in animal forms, and the result would be protection from irritation and normal repair. The more one studies tumor formation in the vegetable kingdom, the more striking will this analogy become.

Comparative pathology will furnish many other arguments. Tumors are common in the lower animal forms and would be found much more so if our observations were more minute and exact. Ten years ago L. Pfieffer described, with extreme care and minute illustration, various forms of tumors occurring in many of the insects and invertebrate animals, all of which were produced by protozoa. The higher we go in the animal scale, the more closely do these tumors resemble those of human beings, until histological characteristics are almost exactly similar. One can not avoid the conclusion that tumors in animals and man are due to the same general causes. If, then, their existence in animals can be proven to be of parasitic origin, it strengthens the conclusions in favor of a similar origin for such lesions in man.

One of the strongest of all arguments, and one which is really irrefutable, is that which we may get from the study of well-known infections which produce tumor formations. Take, for instance, the so-called infectious *granulomata*. *The essential differences between these and cancers are not their histologic structure, but the fact that we know their minute causes.* These tumors which used to be included with malignant tumors have been put in a class by themselves, and their embryologic and every other characteristic taken away from them for the purpose of classification, simply because their causes are now well known; and modern writers have drawn very sharp lines between these tumors about which they have learned much and cancers about which they know but little. And yet these infectious granulomata *are in many instances just as fatal as are the true cancers*, and are amenable to the same methods of treatment and permit of the same general management; *i. e.*, they are distinctly surgical lesions.

Take again the matter of metastasis. There is no known infectious disease characterized by metastasis, from the most acute of the septic or pyemic type to the slowest manifestations of tuberculosis, in which we do not regard metastatic lesions as one of the principal evidences in favor of their infectiousness. Why pathologists have been so loth to see in similar manifestations of cancer a like evidence of its own infectiousness I have never been able to understand. If it means anything in one case it certainly has exactly the same meaning in the other, and yet men have been blind to it for centuries.

Take again the matter of the local infectivity of cancerous lesions. There is the case recently reported of a woman who had an extensive epitheliomatous ulcer on the side, following a large burn. As a result of the *cicatrix, her arm was bound down to her side* and a cancerous ulcer appeared also on the inner side of her arm. Such a case as this means local contact infection, and is more weighty as evidence than one hundred failures to reproduce the disease by implantation. The numerous repeated and now well-known instances in which cancerous infection has followed the track of such instruments as the trocar, for example, afford other evidences whose value is undeniable. Aside from anything that the microscope may show, *a few cases of this kind will have more value than all the failures of all the experimenters of the past century.*

Next to the microscopic appearances of these growths, we have had almost numberless hypotheses advanced to account for the well-known fact that in and between the cells of cancerous growths are seen peculiar forms or particles which have been regarded by some as parasites, by others as products of cell degeneration, and by others yet as pure artefacts. It has been hard for observers to prove that they are cell degenerations and there are wide differences of opinion between those who hold to this view, as well as among those who regard them as parasites. Certain it is that no such appearances are noticed in healthy tissues or in the infectious granulomata or in the truly benign tumors. They must be either cell degenerations or parasites. No one has even been able to reproduce such degenerations under other circumstances, nor are they known or scarcely even named. On the other hand, exactly similar appearances have been produced in large numbers after inoculation or experimentation. In our Buffalo Laboratory, we could show thousands of slides illustrating these familiar appearances. They are inimitable except after the introduction of cancerous material. Thus only they are reproduced.

It is true that observers have differed widely regarding their parasitic nature. Some have regarded them as low animal forms, some as low vegetable forms. Their exact nature is of secondary importance if their parasitic rôle can only be established. The first thing to prove is that cancer is of parasitic origin. Can this be done? It has been done, for instance, in the case of malaria where the parasites are seen inside as well as outside of the blood corpuscles, and, although we as yet know little, if anything, about their biologic characteristics, we nevertheless accept them as parasites. Exactly similar appearances can be noted in and around the cells of rapidly growing cancers, and especially in parts where growth is most recent and rapid. Moreover, if scrapings be taken from a cancer while still fresh and warm, there may be observed under the lens unmistakable ameboid movements of many of these bodies which, when stained in sections, are seen in locations mentioned above.

It is perhaps more or less negative evidence and yet it is perfectly proper to say that in no other way or on no other hypothesis can the peculiar appearances noted in cancer be accounted for. There is simply no other explanation which is at all satisfactory, or can be regarded as tenable.

This is not a question of bacteria. All the investigations made by bacteriologists have failed, and there is no thought now that bacteria are the cause of cancer, their presence being occasionally accidental, but nothing more. Bacteria are by no means the only possible parasites as the history of malaria has proven. It is now a question of organisms about which as yet we know very little; as little, in fact, as the profession in general knew of bacteria when Cohn first began studying them. We turn then from bacteria to some other form of parasitic life as the necessary explanation of known phenomena. Herein lies our greatest difficulty. We are as yet almost in total ignorance of these lowly forms of life and their biologic peculiarities. We do not even know that Koch's laws for the determination of the infectious nature of a given disease are valid here for these forms, since they may not fully apply to such varied conditions. Nevertheless, we may still hold to them until they are proven invalid.

For that matter, we have almost complied with these canons in our Buffalo investigations. In almost every instance, practically in every instance when conditions have been favorable, we have found organisms in cancer cases; and in practically every instance by the introduction of cultures made from these organisms we have produced fatal results in animals, although we can not truthfully say that in every instance we have produced distinct carcinomata. We do not yet know that this can be done in animals by the forms which produce it in man. We know that syphilis and various other diseases are not communicable to animals, and in the beginning of this investigation we must not be too exacting until certain other conditions are also complied with. Where we have so far failed in complying with Koch's canons lies especially in this direction, that we are unable yet to say that wherever we find the organism we find the disease. We do not yet know the cancer organism well enough to be able to identify it outside the human body, and, therefore, while this requirement has not yet been complied with, neither has it been constantly violated.

I have often heard it adduced as an argument against the parasitic theory that the duration of cancer is altogether too long to permit its recognition as an infectious disease. Such statements as these have nothing to justify them. I may be pardoned for calling attention to this fact which I have stated before, because of its importance in this connection. Infections follow no known limit nor time law. There are some which are exceedingly acute, like cholera, bubonic plague, etc.; they kill in a few hours. There are others which run their course in a few days, like pneumonia, tetanus, diphtheria, etc. Still others extend over a period of a few weeks, like typhoid fever and glanders. The time in yet others is only measured by months. This is true of actinomycosis and of tuberculosis, whereas some instances of the latter disease and syphilis extend over years. No matter how long their course may be, we do not decline to see evidences of infection therein, and so the argument against the infectious nature of cancer because it lasts sometimes so long, must fail. Cancer certainly is often as rapid as tuberculosis, even of the acute miliary form, and is usually more rapid than are syphilis or leprosy.

Leaving now the subject of minute agents, let us look at the matter from the purely clinical standpoint. What surgeon of experience can regard the various manifestations of cancer in any other light than as expressions of a slow infectious process? Take, for instance, the case of melanotic sarcoma of the leg. As he sees the gradual transmission of the disease up the limb, and becomes still later aware of the involvement of the liver, then of the lungs, and then of various other parts of the body, how can he help say but that this is a disease which travels along the same paths and after the same fashion as does tuberculosis; or when he sees cancer *en cuirasse* following an operation for cancer of the breast, how can he avoid the conviction that he has here to deal with a slowly creeping local infection which is gradually extending and traveling as only an infection can travel? It was the clinical features of this disease that impressed me with positive convictions as to its infectious character long before I attempted to judge of the same from mere microscopic study.

But, some one may ask, what about the failure of numerous experimenters to reproduce the disease by inoculation, or by implantation? I grant quite readily that until very recent times there has been almost complete disappointment in efforts in this direction. The disappointment, however, has not been so comprehensive as in the case of syphilis, since *every* effort in this direction has failed, and yet we do not deny the infectiousness of syphilis on that account. Because of the paucity of successes in this experimental work there attaches a certain suspicion or uncertainty to every alleged successful experiment. For me, however, as remarked above, one instance of cancer following the use of an instrument, along the track which it has made, is of very great value, far greater indeed than, on the other hand, would attach to one hundred failures in deliberate implantation. Failure does not prove that success may not be finally attained, whereas one positive success is indisputable. Surely clinical observation has amply established the possibility of infection with cancer. Once that be granted, the principal contention is obtained. Failures in times past have been largely due to our ignorance regarding the biology of these minute organisms, and the conditions which favor their life or death. In our laboratory work, for instance, in Buffalo, it has been discovered that they grow best in an exceedingly weak solution, and that ordinary bacteriologic methods and culture media are absolutely inadequate. We have had best results in culture experiments by the use of an expedient suggested by Drs. Gaylord and Clewes in the use of collodion sacs. A little capsule is made of collodion; this is filled with cultures or with fresh fluids; it is sealed with collodion, then dropped into the peritoneal cavity of an animal. The organisms can not escape through the collodion, but there is sufficient osmosis of the living fluids surrounding the sac to permit them to grow, under natural conditions, and they thus undoubtedly grow in the living animal without possibility of escape. Under these circumstances, their virulence is very much enhanced, and it is found that after removal of this sac from the first animal and inoculation of its contents into a second animal, they will produce a very rapid hematogenous infection, with nodular formations in various parts of the body, corresponding exactly to acute miliary carcinosis, the nodules thus produced having often the minute character of adenocarcinoma.

It certainly is not too strong a statement, then, if I claim that in the Buffalo Laboratory Dr. Gaylord and our staff have absolutely produced adenocarcinoma by inoculation in a number of animals, and that this can now be produced in such a way as to afford unmistakable evidence of the infectivity of the disease.

When asked for a minute description of these organisms, it can scarcely yet be given. It must be enough for the present to say that they appear to belong to the protozoa, or possibly, as Schüler has hinted, to some still lower and less known animal form. They can be seen to undergo ameboid movement upon the warm stage, and careful study will reveal numerous changes which they undergo somewhat slowly, by which very positive and somewhat remarkable alterations in size, shape and general appearance are brought about. This would appear to take them out of the realm of the vegetable kingdom, and put them in that of the animal kingdom, and for the present it is enough to call them protozoa. Minute description or detailed statements can hardly be made yet, since they have to be most carefully studied, and, in fact, the whole matter of the biology of these lowly forms of animal life has to be gone over again before one talks too much about them.

These organisms, however, can be, and have been cultivated and successfully inoculated. In ordinary media they grow best in extremely weak solutions. The most successful way that has yet been devised is to deposit them in collodion sacs, as already described, in the living animal. They stand desiccation just as does vaccine lymph, and Gaylord has made some very successful experiments with lymph nodes kept dry for weeks, then rubbed up with sterilized water, and injected.

There seems to be the most absolute resemblance between results obtained in the Buffalo Laboratory and those just published by Max Schüler. There is scarcely a statement which he makes which is not corroborated by our own experiments, whereas almost everything that we have written or found is corroborated by independent statements of his own. The conditions which he portrays in his illustrations and plates are identical with those which can be seen in our forthcoming Annual Report. It seems to me that the statements of Schüler take away almost the last element of doubt which can remain as to the propriety of conclusions regarding the parasitic nature of cancer.

Of course, it is yet too soon to formulate any conclusions regarding its treatment or therapy. For the present, at least, cancer must remain, as it always has been, a surgical disease. I believe this general statement can be made, that if cancer can be recognized early, in accessible parts of the body, and be removed thoroughly, it can be absolutely cured. Unfortunately, early recognition is rare, and thorough removal too infrequent. Consequently, we have the present hideous picture of the disease displayed before the profession. For cancer in inaccessible parts of the body, diagnosis must necessarily be late, and operative treatment can benefit little, if at all. If, however, we can establish a parasitic cause and cultivate a sufficient acquaintance with the organisms at fault, it is not too much to hope that some agent, be it vegetable or mineral drug, or animal antitoxin, may yet be discovered by which the ravages of the disease may be checked or prevented. Drugs are known which destroy the protozoa that cause malaria. Let us hope that something may yet be found, and that speedily, which may have the same destructive effect upon the parasites which produce cancer, without being inimical to the animal cells of the human body. Until this can be brought about, cancer is still a surgical disease, and its discussion by this Surgical Section, or any other association of surgeons, is most proper, and in the interest of surgical science.

EARLY DIAGNOSIS IN CARCINOMA.*

CHARLES A. POWERS, M. D.
Professor of Surgery in the University of Denver; Surgeon to St. Luke's Hospital.
DENVER, COLO.

So far as our present knowledge of cancer goes the nearest approach to its successful management rests on early diagnosis, prompt and thorough operative removal of the widest possible area and a careful and systematic surveillance of the patient during the rest of his life. It would be trite to dwell on the importance of the earliest possible recognition of malignant disease. All surgeons know at what a late day the great majority of cancer cases reach the specialist. The delay is due, 1, to non-perception on the part of the patient or to his fear of being given an unpleasant report, and, 2, to lack of recognition by the medical attendant or to his delay while awaiting the appearance of positive evidences.

The first must be dealt with by the systematic instruction of the laity through suitable lectures of a popular nature, magazine articles and the like. It is the duty of those members of our profession who are competent and whose standing is such as to make their utterances carry weight to thus impress on the non-medical part of the community the importance of early attention to all lumps, growths, persistent ulcers and the like, and the securing of competent advice thereon. Such publicity is not non-professional, but is most commendable. Our brethren who are interested in the matter of pulmonary tuberculosis have accomplished great good in this way; we may learn much from them.

---

* Read in the Symposium on the Surgical Aspect of Carcinoma, before the Section on Surgery and Anatomy, at the Fifty-second Annual Meeting of the American Medical Association.

Further, it is hardly necessary for me to say that our physicians as well as our surgeons should appreciate far better than they do now the vital importance of early recognition in malignant disease. Some years ago I tabulated the cases of cancer applying for treatment at the New York Cancer Hospital during a certain number of months and found that of all cases so seeking admission but 9 per cent. offered any reasonable prospect of cure even after the most radical operative procedure, and that the majority of hopeless cases had been for a longer or shorter period under the care of physicians. Must we not conclude that we, as a profession, are lax in the employment of our ordinary methods of diagnosis, that we must exercise greater care, that we must make better use of the methods which we now possess?

A comparison of the carefully made histologic report on a given neoplasm with the clinical history and examination of the case will most surely instruct the physician or surgeon, fix in him diagnostic methods and lead to the lowest possible percentage of error. Permit me before enlarging upon this thought to briefly lay before you a very few of many recent suggestions:

EXAMINATION OF THE BLOOD.

Hayem[1] states that when we are unable to obtain any physical signs of cancer of the stomach there are a number of symptoms obtainable from a study of the blood. If the latter fluid exhibits no giant and nucleated forms of red corpuscles, and no leucocytosis, we *may exclude the presence of pernicious anemia*. Tentacular and pseudoparasitic forms of red corpuscle with abundant hematoblasts point to cancer. Marked anemia without an anemic murmur suggests cancer.

Hayem refers to a case in which the diagnosis was correctly made by blood examination, but for the sake of absolute proof exploratory laparotomy was performed.

On the other hand, Krokiewicz, writing on "Blood State in Cancer of the Stomach,"[2] says that while much work has been done in this field the reports are conflicting. In 1898, Henry published a statement as to the value of the blood count in latent cancer of the stomach. He attempts to distinguish between this affection and progressive pernicious anemia by the number of red corpuscles in a millimeter cube. In cancer they should not fall below 1,500,000; while in the other disease they go beneath the million mark.

As is well known, several authors diagnose latent stomach cancer when the so-called digestion leucocytosis is absent and when no chlorhydric acid can be recovered from the contents of the stomach.

There is still unanimity in the belief that the hemoglobin of the blood is invariably reduced in cancer of the stomach. But we now know—contrary to what was once taught—that in simple gastric ulcer the same permanent reduction in the amount of hemoglobin occurs (it was formerly held that in simple ulcer the red cells lost in connection with vomiting were rapidly regenerated).

The author's own experiments, however, have taught him the untrustworthiness of these signs which are connected with the state of the blood and gastric juice. Thus he found digestion leucocytosis in four cases out of seventeen, and also noted the persistence of chlorhydric acid in the stomach contents in certain instances. He is therefore inclined to minimize these diagnostic resources.

EARLY DIAGNOSIS OF CANCER OF THE STOMACH THROUGH THE PRESENCE OF THE FILIFORM BACILLUS.

Ehret, assistant to Prof. Naunyn[3] of Strasburg, publishes a communication on this subject.

The study of the flora of the stomach has been largely neglected. A large variety of micro-organisms are found in the stomach contents introduced with the food and air which have been swallowed, but we now know that while the presence of a given organism in small quantities has no necessary pathologic significance, the reverse is the case when any of these organisms are found in large amounts.

The fact that any form of germ life is able to multiply within the stomach is an argument in favor of the existence of an abnormal condition of that stomach. If the normal motility and chemism of the stomach are disturbed, stagnation, etc., would contribute powerfully to the multiplication of germs; and on the other hand, these multiplied germs may themselves possess the power of causing some form of fermentation.

When the microscope shows the constant presence of a certain micro-organism in considerable amount and upon every slide examined, we may regard the germ in question as having some sort of pathogenic significance, either as cause or effect. The multiplication of germs may represent either the cause or the result of an abnormal state of the stomach.

After these preliminary notes the author proceeds with his description of the filiform bacillus. All observers in the field of pathologic fermentations of the stomach have doubtless recognized a peculiar micro-organism in *cancerous stomachs*—a thin, very long, thread-like bacillus present to such an extent that it occupies a large portion of the field of the microscope. This germ shows true ramification. Associated with it we find yeast, sarcinæ, and cocci and bacilli of various kinds.

Boas was the first to describe this organism in his work on diseases of the stomach and he also remarked as to the frequency of its occurrence in cancer. In 1895 Schlesinger and Kaufmann succeeded in making cultures of the germ. They also ascertained that the culture was able to cause lactic acid fermentation and thereby perhaps account for the presence of this acid in cancer. The germ grows on agar with 1 per cent. glucose, forming on the second day colonies the size of a pinhead, white, dryish and almost transparent, looking under the lens like flocculi of wool.

Some confusion may arise between the filiform bacillus and the bacillus butyricus, but the culture is shorter and less thread-like. It is often difficult to obtain the filiform bacillus in pure culture. However, it is hardly necessary to obtain cultures in order to make a diagnosis.

Ehret believes that the presence of this bacillus in the stomach contents is destined to be of great service in the early diagnosis of cancer before other symptoms are present. In the first place this germ is practically absent from the healthy stomach, both to the microscope and cultures. When present it is usually in vast amounts occupying perhaps almost an entire field of the microscope.

The author found the filiform bacillus in 29 patients at the Strasburg clinic; and in 25 of these cases cancer of the stomach was shown to be present. In the other 4 a diagnosis of cancer could not be made. It is not claimed that the bacillus is pathognomonic of cancer but of extreme stasis of the stomach such as occurs in obtained. Failures in times past have been largely due to our ignorance regarding the biology of these minute organisms, and the conditions which favor their life or death. In our laboratory work, for instance, in Buffalo, it has been discovered that they grow best in an exceedingly weak solution, and that ordinary bacteriologic methods and culture media are absolutely inadequate. We have had best results in culture experiments by the use of an expedient suggested by Drs. Gaylord and Clewes in the use of collodion sacs. A little capsule is made of collodion; this is filled with cultures or with fresh fluids; it is sealed with collodion, then dropped into the peritoneal cavity of an animal. The organisms can not escape through the collodion, but there is sufficient osmosis of the living fluids surrounding the sac to permit them to grow, under natural conditions, and they thus undoubtedly grow in the living animal without possibility of escape. Under these circumstances, their virulence is very much enhanced, and it is found that after removal of this sac from the first animal and inoculation of its contents into a second animal, they will produce a very rapid hematogenous infection, with nodular formations in various parts of the body, corresponding exactly to acute miliary carcinosis, the nodules thus produced having often the minute character of adenocarcinoma.

The author's own experiments, however, have taught him the untrustworthiness of these signs which are connected with the state of the blood and gastric juice. Thus he found digestion leucocytosis in four cases out of seventeen, and also noted the persistence of chlorhydric acid in the stomach contents in certain instances. He is therefore inclined to minimize these diagnostic resources.

EARLY DIAGNOSIS OF CANCER OF THE STOMACH THROUGH THE PRESENCE OF THE FILIFORM BACILLUS.

Ehret, assistant to Prof. Naunyn[3] of Strasburg, publishes a communication on this subject.

The study of the flora of the stomach has been largely neglected. A large variety of micro-organisms are found in the stomach contents introduced with the food and air which have been swallowed, but we now know that while the presence of a given organism in small quantities has no necessary pathologic significance, the reverse is the case when any of these organisms are found in large amounts.

The fact that any form of germ life is able to multiply within the stomach is an argument in favor of the existence of an abnormal condition of that stomach. If the normal motility and chemism of the stomach are disturbed, stagnation, etc., would contribute powerfully to the multiplication of germs; and on the other hand, these multiplied germs may themselves possess the power of causing some form of fermentation.

When the microscope shows the constant presence of a certain micro-organism in considerable amount and upon every slide examined, we may regard the germ in question as having some sort of pathogenic significance, either as cause or effect. The multiplication of germs may represent either the cause or the result of an abnormal state of the stomach.

After these preliminary notes the author proceeds with his description of the filiform bacillus. All observers in the field of pathologic fermentations of the stomach have doubtless recognized a peculiar micro-organism in cancerous stomachs—a thin, very long, thread-like bacillus present to such an extent that it occupies a large portion of the field of the microscope. This germ shows true ramification. Associated with it we find yeast, sarcinæ, and cocci and bacilli of various kinds.

Boas was the first to describe this organism in his work on diseases of the stomach and he also remarked as to the frequency of its occurrence in cancer. In 1895 Schlesinger and Kaufmann succeeded in making cultures of the germ. They also ascertained that the culture was able to cause lactic acid fermentation and thereby perhaps account for the presence of this acid in cancer. The germ grows on agar with 1 per cent. glucose, forming on the second day colonies the size of a pinhead, white, dryish and almost transparent, looking under the lens like flocculi of wool.

Some confusion may arise between the filiform bacillus and the bacillus butyricus, but the culture is shorter and less thread-like. It is often difficult to obtain the filiform bacillus in pure culture. However, it is hardly necessary to obtain cultures in order to make a diagnosis.

Ehret believes that the presence of this bacillus in the stomach contents is destined to be of great service in the early diagnosis of cancer before other symptoms are present. In the first place this germ is practically absent from the healthy stomach, both to the microscope and cultures. When present it is usually in vast amounts occupying perhaps almost an entire field of the microscope.

The author found the filiform bacillus in 29 patients at the Strasburg clinic; and in 25 of these cases cancer of the stomach was shown to be present. In the other 4 a diagnosis of cancer could not be made. It is not claimed that the bacillus is pathognomonic of cancer but of extreme stasis of the stomach such as occurs in cancer. In the non-cancerous cases there was present a condition of pyloric stenosis, or of complete atony, as shown by the fact that the sound introduced into the fasting stomach gave exit to matters ingested many hours previous.

Ehret relates a case as follows: A woman, aged 49, always robust, began to suffer from indigestion. She received intestinal antiseptics without benefit. Two weeks later the stomach sound was used after a trial breakfast. Traces of lactic acid were found (chlorhydric acid .004). The filiform bacillus was present in great quantities. The patient was examined under narcosis after inflating the stomach with CO_2, but no evidences of cancer were found.

Operation was refused, and after six months' delay a tumor was recognized, associated with failure of the general health. The patient lived a year; after death no autopsy was obtained but no doubt could be felt in regard to diagnosis.

Ehret closes by reiterating that the discovery of the filiform bacillus in large amounts in the stomach contents justifies a diagnosis of cancer.

DIAGNOSTIC REACTION FROM THE USE OF CANCER-SERUM.

The various serums which have been put forth for the treatment of cancer, and which are thought by some to exert a specific though not a curative influence upon cancer tissue, seem at times to be accompanied by an alleged reaction when injected into the body.

Thus Bra and Mongour's[4] "nectrianine," a serum prepared from the parasite of the so-called "cancer of trees," is without effect if injected into healthy animals; but in man and animals with cancer injections produce a rise of temperature of from 1 to 3 degrees in from two to four hours. Larger doses provoke chills, quick pulse, cardiac palpitation, headache and thirst. The *crisis terminates at the end of some hours* in polyuria and profound sleep. Similar reactions have been claimed for other cancer serums. The latest one to be exploited is Whaeff's bird serum, made by the Pasteur Institute at Paris. Analogy between this and tuberculin as a diagnostic agent will readily be apparent.

AUTO-INOCULATION AS AN AID IN THE EARLY DIAGNOSIS OF CANCER.

Güntz[5] proposes the inoculation of suspected cancer tissue upon the bearer, on the assumption of the infectious nature of the process. He further takes into account the possible source of infection from some other person, with long interval of latency. For example, a man with an incipient, as yet unrecognizable cancer of the lip, may *take his wife's nipple* in his mouth and thereby propagate in her a cancer of the breast. Similarly cancer of the uterus may be due to infection from a latent focus of cancer in the husband's penis. The author's views are best shown in the following case which he reports:

A robust woman, aged 33, good family history, bore a child when 21 years old. The infant lived but eight weeks. The woman and her husband lived together for ten years after this event, and then suddenly—one year ago—she began to look miserable and prematurely old. The husband observed about this time a sort of subcutaneous itching in the inguinal region, which heralded the formation of a sebaceous tumor not connected in any way with the inguinal glands. It enlarged slowly. (Five years earlier a similar wen had appeared in the frontal region near the internal angle of the eye. This had been extirpated on suspicion of being cancerous.) Examination, however, showed that it was only a wen, and since that time there has been no tendency to recurrence in the scar.

During the past four months the husband, who cohabits regularly with his wife, noted some scalding upon urination after coitus, but without any accompanying discharge. The woman's condition, already mentioned, now compelled her to take to bed. The symptoms were those of nervous break-down of an extreme type. There was some pigmentation on the face like that seen in pregnancy. This attracted attention to the uterus. The rapid emaciation and pigmentation suggested a suspicion of cancer of the uterus, but there had been no discharge nor irregularity of the menses. Finally, however, there was a sudden escape of fluid from the uterus which indicated some ulcerative process. The diagnosis of cancer soon became apparent in the opinion of several consultants. After a normal menstruation symptoms of cancer became latent again, the woman appearing quite well. The husband had connection as usual and thereby caused his wife to bleed a little, while he suffered from the scalding of the urine afterwards.

A few days later the little wen in the husband's groin started to inflame. Within eight days it resembled a bubo and was of the size of a pigeon's egg. An artificial opening gave exit to pus. The abscess healed with persistence of an indurated node.

In the meantime it was thought best to extirpate the supposedly cancerous uterus and as a matter of fact a nodule of cancer, as yet intact, was found in the portio. The patient made a good recovery.

Güntz's article ends here abruptly with the statement *that he will publish the rest of the case.* This he has never done and thus his paper is somewhat obscure, but his theory seems to be as follows: Being principally a syphilographer Güntz is simply endeavoring to apply the principle of *confrontation* to cancer. If he suspects that an individual has an incipient or latent cancer he examines the persons with whom the suspect is most intimate. He is aware, of course, that in cancer of the uterus we do not find cancer of the husband's penis, but *this may be due to the fact that the cancer germ does* not cause a lesion at the point of contact but is absorbed and deposited elsewhere. In this locality it may not cause an outspoken cancer, but may give rise to a precancerous lesion or latent cancer, such as a wart or wen, which may remain as such through life without becoming malignant.

In his case, therefore, he believes that a latent or incipient cancer of the uterus transferred some of its germs to the male urethra, where only slight local initiation was occasioned. The germs entered the circulation or lymphatics and finally caused sebaceous tumors, which frequently become cancerous. The practical lesson here would be to consider many benign lesions as essentially precancerous, especially if there is *actual cancer in some intimate. As a focus of cancer* germs such a lesion should be extirpated, for if it does no harm to the bearer the germs may be transferred to some other person with a worse result.

Cabot[6] has recently made a most interesting observation on accidental inoculation in cancer. His patient was a *man of 59 years* with a cancer high up in the anterior wall of the rectum. Removal was made by the Kraske method. The cancer was dragged down into the posterior opening and removed through it. During this manipulation the cauliflower-like, juicy growth was rubbed about in close contact with the operative wound. Two years later, the patient having been quite free in the interval, a cancerous mass histologically similar to the primary disease was removed from the posterior scar where at the original operation the cancer juice had had contact. The original site was free and separated by five or six inches of healthy tissue from the secondary one. Further, the lymphatics from the primary area lead up into the lumbar glands rather than down toward the place of recurrence. The case seems plainly one of accidental auto-inoculation.

Other observations on these and similar lines might be cited did time permit. You will, perhaps, permit me to generalize the result of a careful examination of the literature, and this is to the effect that thus far nothing seems to be proven. Individual cases are given rather than series of cases. Our diagnosis of cancer must rest on our clinical appreciation of the various symptoms, this supplemented by microscopic examination.

Disparity of opinion exists as to the employment of trial excision for microscopic examination. Many surgeons resort to it as a routine measure in doubtful cases where the tissue is accessible. Others believe any incision of cancerous tissue liable to spread the disease, while in the precancerous stage the microscope may reveal nothing and thus valuable time may be lost. In this connection no less distinguished a surgeon than Jonathan Hutchinson[7] says that he has often felt it his duty to urge that the microscope is of no value in diagnosis of the precancerous stage of cancer. He has long been a warm advocate of early operation, even before a diagnosis could be made with certainty; in a well-defined case the microscope is unnecessary, in a doubtful case it can furnish us no assistance.

In other words, cancerous growths, recognized as such from their mode of growth, etc., by the educated eye, are not cancerous histologically. A negative result from the microscope begets a false security and leads to irreparable loss of time. This opinion is not intended to reflect upon the pathologist, for the precancerous stage of cancer consists almost invariably of the histological picture of chronic inflammation.

Hutchinson has recently had four cases of cancer under his care which illustrate this uselessness of the microscope. One case was a large, characteristic epithelioma of the soft palate, almost inoperable. The patient said that eighteen months before he had had a piece excised for microscopic study. The diagnosis had been that of a non-cancerous affection. Clinically he had had a white patch on his palate for at least three years. At the time the trial excision was performed the growth might have been safely removed. In another case the patient had a similar experience. An ulcer formed at the side of the tongue and a distinguished surgeon made a diagnostic excision. The pathologist reported negatively and four months' time was thereby forfeited. Diagnosis having become certain, one-half of the tongue was excised. In a third case a patient had primary cancer of the pharynx with secondary glandular enlargement. There was the same history of diagnostic excision and negative report. The fourth case was quite similar in character to the second. Since these four cases all occurred to him within one month it may be assumed that these erroneous diagnoses are being made constantly. He has himself seen many such. He once removed an entire tongue for what he diagnosed as a broken-down and suppurating cancer. The pathologist reported "no cancer, only an abscess." A few months later the glands beneath the jaw enlarged and the subsequent history of the case confirmed the diagnosis. Upon learning of this tissue the pathologist re-examined the original specimen and found evidences of epithelioma. In a case of cancer of the palm of the hand, microscopic sections of which were examined by pathologists of England, the Continent and America, there were the greatest differences in opinion, some finding evidences of syphilis. The patient died of secondary cancer.

Halsted[8] says that tumors should never be harpooned nor should pieces ever be excised from malignant growths for diagnostic purposes. He believes that there is great danger of rapid dissemination of the growth from injecting cancer of the tongue with cocain and then snipping off a piece of the tumor with the scissors.

Halsted says that in studying the published histories of cases of malignant tumors, particularly sarcoma, he has been impressed with the great number of cases in which general dissemination of the neoplasm has seemed to follow swiftly upon exploratory incisions.

On the other hand, Kelly, Halsted's colleague, seems to resort to trial excision in all doubtful uterine cases. Cullen, in his admirable work on "Cancer of the Uterus," describes at length the simple methods of removal of uterine tissues for examination. Frozen sections, he says, give satisfactory diagnosis in fifteen minutes. It is needless to say that the greatest care must be taken to prevent confusion of specimens.

Colderini (International Congress, 1900) places great dependence upon examination of the scrapings in suspected cancer of the body of the uterus. According to him it is not necessary to find fully developed cancer tissue in order to make a diagnosis. Since cancer of the body is almost always of the type known as adenocarcinoma, it is enough to find an atypical arrangement of the glandular tissue of the mucosa. He narrates a series of cases in which the diagnosis was unhesitatingly made from such atypical arrangement, and confirmed by results of operation.

I believe that I am correct in stating that at this time the majority of experienced surgeons resort to trial excision in suitable, doubtful cases. All recognize the element of error which may be present in an individual instance, yet in a series of cases a suitable piece taken from a typical portion of the growth in the presence of an experienced pathologist and at once transferred to him will give a fairly authentic diagnostic result. My own experience in this has been favorable. While on the one hand I am not certain that no avoidable spreading of the disease has been occasioned, on the other I can not recall an extension which can be so traced and I can cite a fair number of so-called "cures" of three or more years' standing, in which a positive trial excision was promptly supplemented by wide removal of the growth. These especially in cancer of the lip, skin of the extremities and face, breast and rectum. I am inclined to believe, however, that this trial excision should be avoided when possible and that it is always best to be prepared for immediate operation; the greater the surgeon's experience the greater reliance will he be able to place on his general estimate of the individual case.

It is not difficult to say that the physician or surgeon should recognize cancer by the eye and fingers as well as by the microscope, yet his ability to do this will be in proportion to his practical experience and the careful study of his cases; we must not lose sight of the fact that in the great majority of instances early diagnosis is dependent on the family physician rather than on the skilled specialist.

As has been said, I have been personally impressed with the value of diagnostic excision. Whether or not this is wise there can be no question as to the absolute value of the most painstaking and far-reaching microscopic study of all tumor tissues after removal. This study should be made in direct connection with the history of the case and the clinical examination of the patient, and the findings should be verified by the operator himself. In the one column of his case-book may be placed his provisional clinical diagnosis; in another the pathologist's report. A comparative study of these will be productive of the greatest good. On *the one hand we have the family and life history of the* patient—the onset, duration and course of the growth; its general characteristics, resistance, "feel," tenderness, mobility or fixation; the condition of the skin or mucous membrane, of the deeper parts and glands; the blood examination if you like; in a word, all possible factors which can lead to provisional diagnosis. On the other hand lies the pathologist's report. Constant, comparative study of the two will lead to an increasing probability of accuracy in diagnosis.

I do not know that we can at this time go beyond this. In the smaller cities there is a great and increasing need of careful and capable pathologists. The accuracy of our work must be determined by them. Not long ago a well-known surgeon of Boston said to me as we were going through the superb Municipal Hospital there: "When Councilman came to this hospital he revolutionized our methods; we surgeons found that we had to live up to him and his work." We, whose lot is cast in the smaller places, must strive without ceasing for better laboratory work. Our laboratories must be consolidated, enlarged and endowed. It is not enough that the clinicians in the great centers should be in close touch with the pathologists; those in the minor cities and towns must enjoy a like privilege. Happily, facilities for the better training of pathologists are increasing rapidly.

In a recent presidential address before the Association of American Physicians, Professor Welch, the distinguished scientist, compared the opportunities enjoyed in this country by the men who desire to study the branches of scientific medicine and the opportunities open to those who wish to become proficient in clinical medicine and surgery. There are laboratories in this country, equal to any in the world, that are open to young men who have graduated and who wish to become teachers of anatomy, physiology or pathology. In these laboratories a young man must serve his apprenticeship, but Professor Welch says that his promotion is sure. May I not ask you whether (and this especially in the smaller places) we as clinicians recognize as we should the value and the importance of the work which these scientists do, and whether we sufficiently aid in making it possible for them to devote their lives to the purely scientific side of our calling? It is in this direction that advance is to be made, and it is in this direction that our duty lies; a duty seen by such wise and earnest men as Roswell Park, whose Buffalo Laboratory for the study of cancer attracts the attention and admiration of the medical world. Not all of us can create such laboratories, but we can all do something toward a better appreciation of the importance and value of the most painstaking, thorough and far-reaching laboratory investigation.

SOME PHASES OF MALARIA.*

J. B. McELROY, M.D.,
STOVALL, MISS.

On February 12, of this year, I was called to come quickly to see N. M., who the messenger said was speechless. He was a well-developed, strong negro man, 60 years of age, his family history good. He had smallpox about thirty years ago, since which time he has not been sick enough to require the services of a physician. He has never had syphilis, gonorrhea, nor rheumatism. He has lived in the Mississippi Valley eleven years, during which time he has had frequent attacks of "dumb chills." For four days prior to this illness, he had daily paroxysms of fever, which came on about noon. At 11 p. m., February 11, he had a hard chill which lasted for two hours. The fever rose quite high and was attended with vomiting. The patient became delirious, and from 2 a. m. to 9 a. m. he was comatose, his wife being unable to arouse him by calling, shaking or pinching. The coma was attended by stertorous breathing. I saw the patient about 10 a. m. He was complaining of headache and a slight burning sensation about his knees. Over each knee were large bullæ, extending from a few centimeters above the upper border of the patella to a few below the tubercle of the tibia. There were also two of much smaller size about the middle of the leg anteriorly. On the very black skin of this patient, these bullæ looked like burns of the second degree. The patient, in his delirium, had run across the room, taking his seat in a chair which sat before an open fire-place, in which were a few coals of fire. His wife states positively that he did not fall into the fire. His clothing was not burned. The temperature was 102 F., pulse 88, respiration about normal. The tongue was large and flabby, covered with a white coat; the mucous membranes were of fairly good color; the bowels were constipated, the spleen was enlarged, being palpable at the costal margin. The blood showed numerous estivo-autumnal parasites, all apparently of the same stage of development—about one-fourth the size of the red blood corpuscle. The urine did not show any albumin nor sugar.

Under vigorous antimalarial treatment for seventy-two hours, the fever subsided and did not return. The bullæ were pricked and a rather dark serum exuded. The places were dressed with gauze greased with vaselin. The patient was told to report if his legs gave him any trouble. I was called to see him again after about four weeks. I found gangrenous patches over areas referred to above, involving the skin and subcutaneous tissue. The ligamentum patella was exposed in the left leg. There was a gangrenous odor and the tissue was sloughing. The temperature was 99 F. The blood showed a few endoglobular, ring-form parasites and several estivo-autumnal gametes; red blood corpuscles, 4,028,000 per cm.; leucocytes, 6400. The differential count showed polymorphonuclears, 68.5 per cent.; small mononuclears, 23 per cent.; large mononuclears, 8 per cent.; eosinophiles, .5 per cent. Under the influence of quinin and antiseptic poultices, the gangrenous tissue sloughed away, leaving quite large ulcers which I show in the accompanying photographs.

The object in thus presenting this case in detail is to discuss some of the phases of malaria suggested by it, which are exceedingly interesting to practitioners in malarial regions. The first phase which I desire to call attention to is

---

* Read at the Fifty-second Annual Meeting of the American Medical Association, in the Section on Practice of Medicine, and approved for publication by the Executive Committee: Drs. Frank Billings, George Dock and J. M. Anders.

PERNICIOUSNESS IN MALARIA.

The clinical forms of pernicious malaria have been recognized since Torti's classic description of the periodic pernicious fevers, in 1743. These do not differ materially from the graphic description by Dr. Joseph Jones, of New Orleans, of these fevers occurring in the southern portion of the United States.

Marchiafava and Bignami state that "since the time when the parasites of the tertian and quartan were first known, there is no instance on record of a malignant infection caused by them, and no autopsy has ever been made in connection with a spring tertian or quartan." However, in this country, a few cases showing pernicious symptoms in infections with the benign parasites have been reported. They must, therefore, be regarded as exceptions to the general law that "the malignant infections are caused by the summer-autumn varieties of the malarial parasites." My experience has been that the large majority of cases of malarial fevers occurring in the Mississippi Valley are estivo-autumnal infections.

Estivo-autumnal Infection, with Multiple Spontaneous Gangrene

It is a well-known fact that in these infections the estivo-autumnal parasites are found in exceedingly large numbers. If this is not shown in the blood from the peripheral circulation during life, the autopsy usually shows them markedly increased in the viscera. It also appears that there are usually two predominating broods of parasites, sometimes more, in the blood of patients with pernicious fever. But Marchiafava and Bignami report cases in which the viscera, as well as the peripheral circulation, show a very small number of parasites. Dr. Ewing emphasizes this point in his report on the cases of malaria at Montauk Point. The cases of pernicious fever where only one brood of the parasites is present, as seems to be the condition in the case I report, are not infrequent. So it is evident that we must look for the cause of malignancy in another direction than merely in the large quantity of parasites.

These causes may be found in what has been termed the biologic characteristics of the estivo-autumnal parasites. The first of these is their capacity for rapid propagation. This is seen in the great number of young forms which are seen in the blood a few hours after the beginning of the paroxysm. It is another characteristic of these parasites to disappear from the peripheral circulation to complete their cycle of development in other vascular areas.

The pathologic anatomy of these fevers teaches us that there is a decided tendency for the adult forms and forms of fission to accumulate in the capillary network of certain organs, e. g., the spleen, where the circulation is physiologically slow; in the brain, where the lumens of the vessels is small; and in the capillaries of the gastro-intestinal tract. Indeed, it has been proposed to explain the cerebral and choleriform types of these fevers by the mechanical obstruction thus produced in the respective areas. Frerichs thought this obstruction in the cerebral capillaries was produced by thromboses of malarial pigment. Laveran recognized the parasitic nature of these thromboses. Marchiafava and Bignami state: "Only exceptionally do we find in the cerebral vessels free pigment (thromboses of pigment), or masses of melaniferous leucocytes (thromboses of phagocytes), or rarely also free adult parasitic forms or accumulations of free spores (parasitic thrombi in the proper sense of the term)." But they attribute the cerebral hyperemia to the accumulation, in the cerebral vessels, of red blood corpuscles loaded with amebæ, this stagnation being brought about by the degenerative changes wrought by the parasites in the red blood corpuscles, which impair their capacity for free circulation.

Estivo-autumnal Infection, with Multiple Spontaneous Gangrene.

No doubt we should attribute great weight to the mechanical theory in explanation of these symptoms. Another factor, however, must be taken into account in these as in other forms of pernicious malaria, viz., the virulence of these parasites.

Many attempts have been made to demonstrate a malarial toxin, chief among which are the experiments of Professor Celli. The injection of 25 c. c. of serum, from a case of comatose malaria, into a little child, failed to show any toxic effect. The experiment to find the toxin shut up in the red blood corpuscles proved equally futile. Still, almost every one now speaks of the toxin or toxins set free at the time of sporulation of the parasites. There is good evidence for believing that a malarial toxin exists, although it can not be demonstrated, so it is probably this property of the estivo-autumnal parasites more than any other which accounts for malignancy in malaria.

It is known that many uninfected corpuscles give up their hemoglobin. The presence of brassy corpuscles, *the ottonati,* shows the toxic effect of the parasite in its endoglobular phase.

Another proof of the great virulence of these parasites is the occurrence of hemoglobinuria in these infections. It has been stated by a distinguished authority that hemoglobinuria is not malaria, because he has been unable to observe the correspondence between the amount of hemoglobinuria and the number of parasites in malarial fever; and in his series there was no case in which hemoglobinuria was present with a large number of parasites, whereas in many cases with a large number of parasites no hemoglobinuria was present. As against this view it is interesting to note the findings of the Malaria Commission to the Royal Society. It tabulated a series of 28 cases, including 17 reported by Koch, 3 by Ollwig, and 5 studied by the members themselves, in British Central Africa; and show that of these, 75 per cent. showed malarial infection. It also points out that of 21 postmortems in cases of blackwater fever, 90 per cent. showed malarial infection. In these cases, we most infrequently are unable to find the parasite in the peripheral circulation during the attack. I have seen them in only two of nine cases in which the blood was studied. But the blood affords other evidence of malarial infection than the presence of parasites in it, viz., the presence of pigmented leucocytes, and the characteristic leucocyte variation of malarial infection. There were pigmented leucocytes in all the cases studied by me. This pigmentation was seen especially in the large mononuclears. It has been stated that there is a true leucocytosis in these cases, i. e., an absolute increase in the white cells and a relative increase of the polymorphonuclears. I do not believe this statement is correct. Numerous observers have noted that there is often a large increase of white cells in pernicious fevers. Dr. Thayer reports one in which there was an enormous increase, but the differential count showed the characteristic variation of malaria—an increase of the large mononuclears at the expense of the polymorphonuclears. The malaria commission appointed by the Royal Society has made more extensive investigation of the leucocytes in the estivo-autumnal infections than I have been able to find elsewhere. As a rule, a slight leucopenia was found. During the intermission or the remission, when marked, there was a relative increase of the large mononuclears; but during the paroxysm of fever, the polymorphonuclears were not only reduced, but sometimes increased. The large mononuclears were increased at the expense of the polymorphonuclears when the large forms of the parasites were in the blood, and the polymorphonuclears were not decreased when the small forms were present. I have been able to confirm these observations in several counts recently made. In all 5 cases studied by them they found an absolute increase in the white cells, and the leucocytic variation characteristic of malaria. I made differential counts in 2 of the 9 cases referred to by me. One showed P. M. N., 64 per cent.; large L. M., 20 per cent.; S. M., 16 per cent. The blood was obtained during the decline of the fever, near the first intermission. The same patient showed P. M. N., 75 per cent.; L. M., 15 per cent.; S. M., 10 per cent. a few hours before death. Another case showed P. M. N., 64 per cent.; L. M., 19 per cent.; S. M., 16 per cent.; E., 1 per cent. So if pigmentation and leucocytic variations are evidences of malarial infection, where the parasites are few or absent in the peripheral circulation, hemoglobinuria must be malaria, and, being malaria, is a most striking evidence of the extreme virulence of the estivo-autumnal parasites.

Phenomena occurring in these infections, after the disappearance of the parasites, which have been termed post-malarial, are also evidence of the toxin theory. Kelch and Kiener, Mannaberg, and others, have noted the decrease in the percentage of hemoglobin after the disappearance of parasites. Dr. Ewing reports several cases of fatal anemia in his Montauk series, after the disappearance of the parasites. Dr. Thayer has reported a very interesting case of comatose fever, which he regards as post-malarial auto-intoxication. Marchiafava and Bignami state that, "in addition to the post-malarial fevers, there are individual cases of a post-malarial morbid condition, which must be put by the side of those which come after other infectious diseases (typhoid, pneumonia, scarlet fever, etc.)."

Another phase of malaria which the case reported suggests is

IMMUNITY

in malaria as it relates to the negro. We not infrequently see it stated that the negro is relatively immune from malarial infection, and sometimes that he is absolutely so. These statements are not in accord with my experience of eight years with the negro in the southern Mississippi Valley. Maurel, from his studies *on this subject, concludes that no human race is immune* from malaria, not even the black race.

On the plantation where I reside there were 24 whites last year. Of this number, 41 per cent. were infected with malaria. Of this number, however, 5 did not have malaria, and were away from home during the greater part of the malarial season. Excluding these, the malarial morbidity would be about 53 per cent. among the whites. There were 184 blacks; of these 61 per cent. were infected.

I have tabulated 20 cases of pernicious fever which I have seen since June, 1900, showing:

No.	Age.	Race.	Term of Residence. Days.	Month.	Type.	Result.
1	34	White.	34	June.	Hemoglobinuria	Recovery.
2	4	Black.	4	June.	Cardialgic	Death.
3	7	Black.	7	July.	Comatose.	Death.
4	60	Black	20	July.	Hemorrhagic, Melaena.	Death.
5	15	Black.	2	July.	Bilious continuous	Death.
6	3	Black	3	August.	Cerebral, convulsions	Recovery.
7	35	Black.	12	August.	Hemoglobinuria	Recovery.
8	55	White.	55	August.	Hemoglobinuria	Recovery.
9	4	Black.	3	August.	Comatose.	Recovery.
10	11	Black.	5	August.	Comatose.	Recovery.
11	5	Black.	5	August.	Cerebral, convulsions	Recovery.
12	55	White.	55	August.	Cerebral, delirium.	Recovery.
13	10	Black.	2	September	Comatose.	Recovery.
14	10	White.	1	September	Comatose.	Recovery.
15	18	White.	18	September	Hemoglobinuria	Recovery.
16	10	Black.	10	September	Comatose.	Recovery.
17	38	White.	10	September	Hemoglobinuria	Death.
18	30	White.	12	November.	Hemoglobinuria	Death.
19	60	Black.	12	February.	Comatose.	Recovery.
20	5	White.	60	February.	Comatose.	Recovery.

Of this number it will be seen that 12, or 60 per cent., were negroes. The mortality among negroes was 33 1/3 per cent.; among whites, 25 per cent. Indeed, I have seen the comatose, convulsive, cardialgic, gastric, choleriform, hemorrhagic and hemoglobinuric types occur in negroes, and in some death resulted.

The next phase which this case suggests is

GANGRENE IN MALARIA.

Several cases have been reported by Petit and Verneuill, in reviewing the occurrence of gangrene in connection with Raynaud's disease. These and others have been referred to by Barlow and Monroe. Osler reported a case of multiple spontaneous gangrene occurring in an estivo-autumnal infection, in the *Bulletin of the Johns Hopkins Hospital,* in February, 1900. He classifies three groups of gangrene: 1. In connection with Raynaud's disease. 2. Multiple spontaneous gangrene, in association with the acute infections, like measles, typhoid fever, typhus fever, scarlet fever, diphtheria, and malaria. 3. Multiple spontaneous gangrene of the limbs in young and middle-aged people without any obvious cause.

The case I report is one of multiple gangrene in an estivo-autumnal infection. I saw another case of spontaneous gangrene last year, which, from the clinical history, I regard as one in association with malaria. I regret very much that I could not get a blood-smear for examination, being without cover-glasses and slides at the time.

On March 27, 1900, the father applied to me for medicine for his child, C. S., a mulatto girl 4 years of age. He said that she had been having chills and fever for some time and was swollen about the face, hands, and feet. I prescribed iron, quinin and bitartrate of potash, under the influence of which, he said, the swelling disappeared. On May 16 I was called to see the child, and found her fairly well nourished. She had quite a high fever, with very rapid pulse and respiration. There was no edema and no eruption on the skin. The mucous membranes were anemic. The lungs were negative. There was no enlargement of the heart, and no cardiac murmurs. There was vomiting. The bowels were constipated; the spleen was enlarged, being palpable below the costal margin. The urine showed no albumin nor sugar. The child was put upon vigorous antimalarial treatment. On May 20, four days after my visit, the father reported that her fever had subsided and she seemed much better, but one foot was cold and apparently dead. The next day I visited the patient and found the right leg very cold as high as the knee, the toes in a state of dry gangrene, the dorsum of the foot black, with a few purpuric spots on the leg. The left leg appeared normal. There was no fever. A careful examination showed no endocarditis; there was no history of rheumatism. There were some pains about the knee on moving the leg. Another careful examination of the urine failed to show any albumin or sugar. I ordered a nourishing diet and tonic treatment, and advised the father to inform me when the line of demarcation formed. I did not hear any more from the patient until about two weeks afterward, when I happened to be passing the house, and asked how the child was getting along. The reply was, "Dat foot done come off." I went into the cabin and found the child sitting on a pallet on the floor, in very good spirits. On removing an old apron in which the leg was wrapped. I saw that spontaneous amputation had occurred at about the upper third of the leg.

DISCUSSION.

Dr. E. H. Martin, Clarksdale, Miss.—I have not many criticisms to make, but I do wish to draw attention to a distinction between the forms of pernicious malaria spoken of; for instance, hemoglobinuria and the comatose forms are all classed as pernicious malaria. Hemoglobinuria may be pernicious, but never in the sense we regard the other. Hemoglobinuria is malignant in that the germs present cause an absolute destruction of the blood cells. The other form is pernicious simply from an overdose of the toxin of malaria. In other words, one is pernicious from an overdose of the toxin and the other from the malignancy of the germs causing a destruction of the blood cells. In the negro we see but few cases of pernicious malaria in proportion to the total number of cases. In adults we see but few cases of pernicious malaria. In small children, especially in the small white children, we have a great many cases; it is quite an uncommon thing for a white family in the swamp lands of Mississippi to raise more than two out of five children, on account of the pernicious malaria, and the reason, I think, is evident; the blood of a child is very rich in the pabulum which nourishes the malarial germs; the vital resistance is low, and comparative immunity unattained. A vast number of the malarial germs develop, producing toxin, an overproduction of which kills the patient. I do not think that the mechanical theory can hold good; there is no reason why a few germs, and broken-down malarial organisms, should stop up the capillaries of the brain of a white child and not do the same for a white adult or negro child; yet it is a fact that these children have the "congestive" type almost exclusively. This is the idea that we get in speaking of pernicious malarial fever, that the toxins develop rapidly and in large quantity, and are administered to the patient in lethal doses.

Immunity in the negro is real, but only relative. It is a well-known fact that the number of white people that are affected with malarial troubles is less in proportion to the number of negroes affected than it was supposed to be; this is on account of the use by the whites of gauze doors, mosquito bars, the administration of quinin, etc. The class of "poor whites" who live as the negroes do are nearly all sufferers from acute or chronic malaria.

There is some hemoglobinuria among the negroes; but, where there were 400 negroes and 100 whites, there were 30 cases of hemoglobinuria among the whites and but 1 among the negroes. So, the negro has a relative immunity. Again, this relative immunity may be lessened by residence in non-malarial regions; a negro returning from a residence in New York, for instance, has lost it to a certain extent, but, after he has been in a malarial district for a time this relative immunity is regained. The negro is not fully immune, but is more nearly so than the white man; and the white man who has resided long in a malarious locality has a greater partial immunity than a newcomer.

Dr. William Britt Burns, Memphis, Tenn.—In referring to the immunity in the negro, the word relative, as mentioned by Dr. Martin, is a good one to employ. The negro is not immune to malaria, but he is relatively immune. The negro has malaria in mild form; it is true he has malaria in malignant forms, yet they respond to treatment quickly, much more so than the white people. I have seen several cases of comatose malaria in the black negro, and I have seen them get well; they all get well. I have never seen a case of comatose malaria in the negro terminate fatally, but I have seen many cases among the whites, especially in children. I have no doubt but what the accumulation of the malarial toxins in children is very rapid, and it is a common saying in the delta of the Mississippi valley, in Arkansas and Louisiana, that we must not allow a child to have a second or a third chill; it is the commonest thing to see, in a very large percentage of the cases, a child with congestion or congestive chill who dies. I have seen very few get well in infancy after the paroxysm of congestion came on. I have seen negroes, comatose for hours, get well.

Dr. D. M. Hall, Memphis, Tenn.—I do not live in as malarial a district as those who have preceded me, and therefore I have not seen as many cases of malaria, especially of the malignant type. My experience, however, leads me to believe that the negro is relatively immune. I have seen a great many more cases of malaria among white people than among negroes.

I think that if you take an equal number of whites and negroes, under similar conditions of exposure, etc., a greater number of whites will have malaria than the negroes. I do not know why this is so. We have in the South negroes living in places where the mosquitoes are in droves and where the conditions are good for the production of the disease, and they live there with very little infection; yet, I am sure the white people could not live there without being infected. In one city in the South there is a little creek which runs through the town and a great deal of sewage is thrown into it despite the efforts of the board of health. This is a great breeding-place for mosquitoes and they are there in swarms; near this creek seems to be a favorite place for the negroes; they live there on its banks, in cabins, and they seem to be in good health. Yet the white people who live near there are greatly infected with malaria. Therefore, I do not think the negro is immune, only relatively so. I think he can be overcome by malaria, but this depends upon the quantity of the poison introduced into the system. It requires more of the poison, in a more virulent form, to overcome the negroes than it does the white people.

Dr. Delancey Rochester, Buffalo, N. Y.—I presume it is well known that the mosquito is one of the sources of malaria; I should like to ask the gentlemen present if they recognize any other mode of entrance of the malarial parasite into the body besides the mosquito.

Dr. W. G. Harrison, Talladega, Ala.—The negro is relatively immune to most every disease, except lung troubles. I remember, when a student of medicine, that Dr. Westmoreland, in his lecture, stated that the negro was greatly immune to most of the bad and alarming features of tertiary syphilis. I have watched closely since, and I am sure that what he said was true. I think the negro has some relative immunity to all diseases except those of the lungs. They die from pneumonia and tuberculosis most readily. I saw a family in February where five died from pneumonia in one week; in the same community I had five or six cases among the white men and none died; all had the same kind of medical attention, the same physician, the same nursing, etc. Negroes die rapidly from pulmonary diseases of every kind.

Scientific medicine is being introduced into the Southern malarial swamps. The physicians in Louisiana, Alabama, Georgia, etc., are rapidly learning the use of certain apparatus for the better diagnosis and treatment of disease. It is now necessary that any man who practices in the South should equip himself with a microscope and all other instruments for clinical diagnosis. I have seen many cases, some of them among the negroes, who were taken sick with some inflammatory trouble and they seemed in a fair way to recover, when there was an unexplained rise in the temperature; the microscope revealed the malarial parasite; without it the rise in the temperature could not have been explained. Recently, within the last six weeks, a little girl of 2 years was brought to the hospital with cholera infantum; she got along slowly. Under the use of the saline solution she gradually got better, but, after one week, without any apparent reason at all, there occurred an elevation of temperature. I expected a return of the vomiting and watery passages, but they did not appear. After thirty-six hours an examination of the blood revealed some of the organisms of malaria. Under the proper administration of quinin the patient promptly got well. Regarding the statement that negroes are more susceptible to all diseases, I can only say my experience is very different. They easily contract smallpox, and most of them have latent syphilis, but I am sure the race possesses a distinct relative immunity against all the fevers, stomach and intestinal derangements, rheumatism, gout and many other maladies.

Dr. Victor C. Vaughan, Ann Arbor, Mich.—I saw many cases of malaria in Cuba in 1898, and a large number of these were of the comatose variety. While I can not give any exact figures, I am under the impression that the comatose form of malaria, as we saw it in Santiago, was relatively quite as common among the negro soldiers as among the whites. Some time ago I went through the army records investigating this matter, and while I can not give exact figures, I am confident that the general statement that I have just made is correct. The last speaker surprised me when he stated that the negro is immune to many diseases to which the white man is susceptible. The question of relative immunity between races is an important one, and I do not believe that definite conclusions should be stated until we are sure of the data on which they are founded. Only a few years ago it was believed that the negro was quite immune to yellow fever, but later epidemics have shown that this is not true. When yellow fever prevailed in our army in Santiago in 1898, two companies of the 24th Infantry, composed of negroes, were detailed as nurses on account of their supposed immunity to the disease. Practically all of these negroes became infected, and the mortality was quite as great as it was among the whites. It should be stated that this regiment had long been stationed in the western part of the United States, and possibly the negroes composing it had lost any racial immunity that they may have originally possessed. I have always been of the opinion that the white man is hardier and as a rule less susceptible to the infectious diseases than the negro, and I am surprised to hear it stated here that the negro is largely immune to most of the diseases to which we are susceptible. In this country tuberculosis and pneumonia are the most fatal of the infectious diseases, and certainly the negro is quite as susceptible to either of these as the white men, and the mortality is greater among the blacks. I am also convinced from extended observation that the negro succumbs to typhoid fever quite as readily as does the white man.

Dr. G. W. Goins, Breckenridge, Mo.—I wish simply to ask a question whether, in the practice of any present, many cases with a malarial symptomatology have occurred which simulated more or less typhoid fever and which did not yield to the administration of quinin.

Dr. Louis Schwab, Cincinnati, Ohio—Several of the gentlemen have spoken of a malarial imprint upon other diseases. This has been noticed in the progress of many of the diseases, particularly such that usually run an uninterrupted course. In the Millcreek valley, in which I live, many of the acute infections are observed to be disturbed in their behavior by malaria, and this belief is strengthened by the fact that quinin generally corrects the interrupted course. One reason why, in the treatment of the negro, better results are obtained by remedial agents, is perhaps because doses are more heroically given. This is particularly true where quinin is indicated for malarial affections. The statement that the negro enjoys an immunity from syphilis seems singular and can only be explained by invoking the belief that his immunity exists because he is born with the taint. The frequency with which unlooked-for fatal results occur in the negro is a matter of common observation on the part of those who have much to do with him. Sometimes, with no apparent reason for the fatality, death occurs, and it has been assumed by many that he loses his nerve just at the time he most needs it. It is known that the negro is very impressionable; this is best demonstrated by his conduct at religious exercises where in his excitement he is led to exhibit his fear in the most peculiar manner. It may be that a sense of impending danger lowers his resisting power and explains why he dies when there is no reason for it. Dr. W. S. Christopher, of Chicago, once applied the term "negroitis" to this manifestation.

Dr. Joseph Brayshaw, Berlin, Ill.—In Central Illinois we have a few cases of malaria that so much resemble typhoid fever that a diagnosis can only be made by means of the microscope; but we have a large number of typhoid fever cases that so clearly resemble malaria that were it not for the Widal reaction and the absence of the malarial parasite a diagnosis would be impossible. We frequently have typhoid fever without pea-soup stools, without rose spots, and without very much abdominal tenderness, while we frequently have abdominal tenderness to a marked degree in malaria. The typhoid condition and typhoid tongue are frequent in our cases of malaria.

Dr. T. B. Futcher, Baltimore, Md.—I should like to emphasize one important complication in malaria which Dr.

McElroy has already referred to in his paper, i. e., the occurrence of multiple gangrene in malaria. I was fortunate in having had an opportunity of seeing the case of gangrene of this nature which was under the care of Dr. Osler. The patient was a man, 23 years old, who was admitted to the surgical side of the Johns Hopkins Hospital, with dry gangrene over the dorsum of both feet, the heel of the right foot, and symmetrical patches over the fingers of both hands. There were, also, one or two large patches over the gluteal regions, and two small areas over the occiput. The case was at first a puzzling one from an etiological standpoint. There was slight elevation of temperature, and this, with the existence of an enlarged spleen, led to the examination of a specimen of fresh blood, which revealed numerous typical malarial crescents. This suggested the possible relationship between the malarial infection and the gangrene. Accordingly, the patient was transferred to the medical side and immediately placed upon anti-malarial treatment, quinin being administered in large doses. The patches of gangrene were treated locally. Improvement began at once, and the patient soon recovered from the local lesions. This was the first case of malarial gangrene that we have had at the Johns Hopkins Hospital out of a total of over 2000 cases, and it is undoubtedly an extremely rare complication. The case illustrated the importance, in cases in which the etiology is obscure, of a careful examination of the blood.

I should like to add that my impression in regard to the relative frequency of malaria in the two races in Baltimore, without having definite figures at hand, is that the negro race is practically as frequently affected as the white.

Dr. W. D. Haines, Cincinnati, Ohio—We have all seen delirium tremens follow in the wake of an accident, fracture, etc.; in the so-called moderate drinkers, on the other hand, we have seen malarial fever manifest its influence immediately after some surgical procedure. This would seemingly indicate that the prerequisite principle in either instance lay dormant until some exciting cause demanding extra attention on the part of Nature becomes operative. This is somewhat at variance with the usually accepted theory of disease, viz., that the host must prepare for the reception of the guest. We are exposed daily to the infectious principles of diphtheria, typhoid fever, tuberculosis, etc., and still we do not contract these maladies, forsooth the soil is sterile. On the other hand, how frequently we observe patients with lowered vitality or injury become an easy prey to these infections.

The statement made by one of the speakers, Dr. Harrison, astonished me not a little. He said: "The negro enjoys immunity from syphilis." It seems to me as I now recall personal experience in the treatment of this race that I have seen more cases of active syphilis in the negro than all other races combined. I never ask a negro *whether* he has had syphilis, but *when* he had it.

MEDICAL SHOCK.[*]

O. T. OSBORNE, M.A., M.D.

NEW HAVEN, CONN.

Before discussing what I interpret to be a condition of medical shock, it may be well to say a few words concerning the justification of ever rendering a certificate of death from "heart failure." Far be it from my purpose to excuse, justify, or encourage the use of this term to aid ignorant certifiers of undiagnosed deaths, or to give a mystic covering to illegitimate deaths, whether due to actual malpractice, or to the careless use of active drugs.

It may be said that the certificate of death from medical shock or heart failure is unjustifiable, because, if we seek carefully enough, we will find a cause for the failing heart, such as myocarditis, fatty degeneration, an endarteritis or atheroma of the coronary arteries, etc., which causes, however, can many times be diagnosed only on the autopsy table.

Neurasthenia, which is a condition and not an entity, is recognized as a legitimate cause of death, but the pathology of this condition is more intangible than the condition of heart failure.

I do not wish to advocate the use of the term "medical shock" for conditions of failing heart, due to distinct pathologic conditions, or due to the gradual break-up or overpowering of the system by very acute or prolonged processes, but I think the term justifiable, when a badly acting and gradually weakening heart is the most urgent cause for anxiety, and its weakness is out of all proportion to the pathologic condition or symptoms present.

I believe it to be a fact that the hearts of our patients cause us more and more anxiety every year. If we doubt this statement, we have but to trace the treatment of acute conditions from the period of bleeding, calomel, tartar emetic, or other depletions, gradually down to the present time to find that first there was a cessation of depletions; next, the avoidance of nauseating doses of anything, denoting a greater care of the stomach; next, forced nutrition; then the general disuse of such drugs as aconite and veratrum viride; next alcoholic stimulation, and now we even note the loss of vasomotor pressure from alcohol and use strychnin in its place. This all means that the hearts of to-day do not withstand fevers or other systemic upsets as they formerly did.

To be specific, we are as justified in using the term "medical shock" as we are in using the term "surgical shock," and that the symptoms of heart failure which develop so unexpectedly in acute cases otherwise progressing satisfactorily, are due to this condition of shock. We all know the symptoms, viz., a more or less rapid heart, but with the least movement or excitement made very rapid; a soft, irregular, perhaps dicrotic or intermittent pulse; incomplete inspirations without much actual dyspnea, interspersed with frequent sighs, and the subjective symptom of precordial oppression. The temperature is generally low, the flesh cool and clammy, and if quick relief is not obtained, death will soon take place, caused by heart failure or medical shock.

The pathology of surgical shock is believed to be a paralysis of the vasomotor system, causing primarily a bleeding of the body into the large abdominal vessels, splanchnic paralysis, and secondarily great loss of heat from the dilated surface vessels.

I believe that medical shock is just as certainly a vasomotor paralysis, except, perhaps, in severe acute malignant affections where there may be a great destruction of red blood corpuscles. As a consequence of this paralysis, the major part of the blood is in the abdominal veins. The blood flows slowly into the dilated and, therefore, non-elastic arterioles; hence, slowly in the capillaries, and returning slowly in the veins, but imperfectly fills the heart cavities. The heart, not only from imperfect filling, but also from impaired nutrition, contracts irregularly, incompletely, and arrhythmically. The aorta has not the pressure ahead or the forcible quota of blood from behind, and consequently does not give enough elastic rebound to force blood properly into the coronary arteries, and the heart muscle is improperly nourished. By the lowered pressure, and the normal blood pressure is so vital, all the functions of the body begin to fail, all digestive processes are imperfect, and undoubtedly normal oxygenation is impaired, molecular death begins to take place, at least almost unaccountably gradual failure of body and mind occurs, till death closes the scene.

---

[*] Read at the Fifty-second Annual Meeting of the American Medical Association, in the Section on Practice of Medicine, and approved for publication by the Executive Committee: Drs. Frank Billings, George Dock and J. M. Anders.

Surgical shock is more frequently caused by injuries to certain areas of the body than to others, such as the head, neck, splanchnic region or testicles. Many cases of operative shock are undoubtedly due to the intense pain from severed nerves, without loss of blood.

Returning again to medical shock, we find that severe, acute nerve pain will, if continued, give a lowered vasomotor tension, and if too long continued or too severe, vasomotor paralysis or shock, perfectly similar to that due to profound injuries of these nerves, or surgical shock. The nerves most likely to cause such lowered blood pressure from pain are exactly those which, if injured or operated on, are most liable to cause surgical shock, viz., in the region of the heart, solar plexus, the neck, the head, and the testicles.

We often see this depressed heart and softened pulse from precordial pain, or from a genuine migraine, or biliary and renal colic. The vasomotor depression is quickly shown in these cases, but in any subacute or chronic nerve pain, sooner or later, this condition, possibly mildly evident, supervenes. Even in hysterics and neurasthenics, imaginary pain can and does cause the same depression; in fact, a true neurasthenic is probably not much else than a patient in a chronic state of diminished blood pressure and semiparalysis of the vasomotor system.

Chronic organic diseases without pain do not cause symptoms of shock until profound anemia occurs. In acute fevers a successful issue is generally assured if the heart, and that really means the vasomotor system, can withstand the strain. The strain means the intensity and persistency of high temperature, the amount absorbed of the suppurative or putrefactive products of the pathologic process, plus the absorption of fermentative products due to intestinal stasis, and the central depressing influence of the toxins produced by the specific germ. If we can sustain the vital powers, and what does this mean other than the vasomotor tone, until the elimination of such poisonous products exceeds the absorption, our patient will get well, even if we have to fight through a tedious convalescence, showing the amount of muscle and nerve strain through which the patient has passed. In other words, our whole aim in acute feverish processes should be to make the elimination at least equal to the production of these decomposition and fermentative products, and to prevent the absorption of these products if possible. This means, specifically, to cause all of the emunctories to do good and proper work, or if one is impaired, to increase the action of another, and to keep as clean as possible every localized suppurating or inflammatory process that may be going on. The good results of such treatment are markedly evidenced in typhoid fever. By laxatives and intestinal antiseptics we reduce the temperature, clean the ulcerating surfaces and prevent fermentation from giving more toxins, and from producing that most troublesome condition of tympanites, with its liability to cause hemorrhage and perforation. A considerable portion of the persistently high temperature and bad pulse of typhoid fever is due to the added and often neglected factor of bowel-infection.

In all diseases or conditions where there is a piling-up in the blood of absorbed poisons, be they from typhoid or dysenteric ulcers, pus collections, malarial plasmodia, or hemoglobin debris, cancerous disintegration, or catarrhal edematous mucous membranes, which are such fine culture-grounds for all germs, any treatment that hastens the evacuation of the excreted bile, impregnated as it is with toxins, made temporarily inert by the good offices of the liver mechanism, will prevent systemic and nervous poisoning and ultimately vasomotor disturbance and medical shock.

Hence, in any disease, to forestall the condition which I have termed "medical shock" we should take every means to prevent the absorption of secondary toxins, or in other words, we should endeavor to prevent double infection. We should carefully promote nutrition, not overloading the stomach, stimulate the heart either with alcohol, strychnin, coffee or camphor, as indicated, and stop too acute, or too long continued, subacute pain. Coal-tar antipyretics and analgesics should be used with the greatest care. Of course any hemorrhage should be treated as the surgery of the part decides, and any subnormal temperature by every known method to keep up the normal heat of the body.

If medical shock occurs, we must treat it on the same general principles as laid down for the treatment of surgical shock. All cardiac and vasomotor medication should be administered hypodermically, as the stomach will not absorb in this condition of shock, and the tolerance of enormous doses of active drugs, as digitalis, given by the stomach for the shock of delirium tremens, is due to the very slow or non-absorption of it. Small quantities of hot liquids taken into the stomach can but do good by their warmth.

I have purposely but briefly mentioned the shock due to acute malignant infection, which may be largely profound acute anemia due to destruction of the red blood corpuscles. I have wished to emphasize the frequency and the pathology, as I interpret it, of the attacks of heart failure as we see it in our acute cases. Many deaths attributed to the acute disease present are really due to this condition of medical shock or heart failure. We all frequently have cause to combat, sometimes successfully, sometimes unsuccessfully, these attacks of medical shock. Whether we term this "medical shock," or "heart failure," we know that can we hold this heart and vasomotor system for a short time longer, our patient will recover from the disease which has attacked him.

DISCUSSION.

Dr. C. W. Lillie, East St. Louis, Ill.—It has long been a question whether the term "heart failure" is a proper one to use at any time, and especially as it is condemned by those who are looking for accurate statistics regarding the causes of death. It seems to me that the term, as used in the paper, would seem to cover the conditions produced by a number of influences exerted upon the patient by disease, i. e., by combined influences rather than by shock. The term shock I believe should be restricted to those cases in which there are influences of a direct character applied in such a way as to immediately overcome the vital forces. These influences can be overcome, or prevented, by the use of such general tonics as are indicated, and especially by strychnin. It does not seem to me that the term "medical shock" would be a proper one to apply.

Dr. James J. Walsh, New York City—The term "medical shock" seems to deserve a place in the discussion of certain difficult fatal cases, the etiology of which is as yet unsettled. For a time the term heart failure was employed, but owing to the abuse of it, has fallen into disrepute. There are, however, undoubtedly cases in which owing to the development of some nervous condition the heart stops beating though no lesion can be found postmortem. Most of us have experienced certain cases which, especially those beyond middle life, when attacked by some acute gastric or intestinal condition, are liable to paroxysms of heart disturbance, and may prove fatal. Sometimes death is almost instantaneous and would seem to be due to the shock of pain. It is as if irritation of the digestive ends of the vagus led to irritative reflex, inhibitory impulses that brought the heart to a standstill. This state of affairs reminds one of nothing so much as surgical shock. What the underlying basis for surgical shock is we do not know. It seems an excellent idea, however, to have the analogous term, "medical shock," to apply to certain non-surgical cases, because this will stimulate the investigation of both conditions, so as to solve the important problems they involve.

Dr. C. A. Kelsey, Minneapolis, Minn.—By whatever term we call it, surgical shock, heart failure, or any other term, we all experience the same anxiety when we are confronted with the condition. During the reading of this excellent paper one thought came to me which I would like to discuss here. In diseased conditions where heart failure is liable to occur, is it the wisest plan to fortify the patient against its occurrence, or shall we reserve our agents until the critical moment comes and they are demanded? I have sometimes thought that we make a mistake by crowding the hypodermic injections of strychnin, or other powerful heart tonics, in cases where it does not seem to be positively indicated. I have in mind a case of diphtheria in a child occurring not long since, in which the consultant advised beginning and continuing the use of heart stimulants by the hypodermic method in order to anticipate heart failure. That plan was pursued, the nurses were provided with the hypodermic syringes, and they continued to use the injections. But, when the critical point did come and the heart failed, the heart then refused to respond to stimulation and the patient died. The point I want to raise is this: Is there not a possibility of making a mistake in commencing the heart stimulants before they are positively indicated and thus get the system so accustomed to the stimulants that the heart fails to respond at the critical moment? A man in a race does not use the spur at the beginning, but at the proper moment; if he did use it at the beginning the horse would fail to respond to it when the proper time came.

Dr. George W. Webster, Chicago—Whether we employ the term heart failure, or weak heart, or surgical shock, or medical shock, we should, all of us, be ready, at all times, to recognize the condition. I believe there is no one point on which there is less clearness of conception than in regard to this matter of failure of weak heart, and the conditions which bring about a weak heart. I know that there are many physicians who, when they examine the heart with a stethoscope for the first time, and find no murmur and no apparent intrinsic cause for the heart giving out, pronounce it sound. We should remember that a weak heart may be brought about by overwork due to both intrinsic and extrinsic causes; it may be due to valvular lesion; or the right side may be overworked from causes in the pulmonary circulation, and the like; or the left heart may be overworked from systemic conditions, as a general arterial sclerosis; the heart may fail from toxemia due to many causes, such as alcoholism, gout, syphilis, or from the toxins produced by various acute infections. There are many of these toxins which influence the heart muscle directly, and both the intrinsic and extrinsic nervous mechanism of the heart. Again, the heart may fail from failure of nutrition, which may be due to disease of the coronary arteries, primary or secondary anemias, or reflex causes.

I remember an experience that I had as a medical student about twenty years ago. We had a rabbit upon which we were going to experiment, and that animal was actually scared to death. The conditions found were these: The heart was found to be absolutely bloodless and the abdominal veins were enormously distended with blood; in other words, the animal bled to death into his own veins, the veins presided over by the splanchnic nerves. There was a failure of the heart from the nervous influence. Mental emotion may of itself be sufficient to cause a dilatation in the splanchnic area, so lowering the arterial pressure, causing the heart to fail. If we use the term heart failure we should remember that it is merely a convenience for classifying, not in any definite way, but to cover up a large number of things where we were unable to make an accurate diagnosis.

Dr. R. C. Newton, Montclair, N. J.—I agree with the last speaker in regard to the inadvisability of calling conditions "medical shock" which are due to toxemia, to weakness, to overstraining of heart muscle, and perhaps to overdrugging. I think the term is confusing. If we use this term it will convey to the laity the impression that the physician has done something or allowed something to occur to the patient that could have been prevented. I agree with Dr. Osborne's explanation of the condition, and think that his paper describes vividly a pathological state with which we are all more or less familiar. The paper is interesting and instructive; but it seems to me that if a new name be needed for this condition a better one might be found than the one the Doctor suggests.

Dr. Osborne, closing—I have but little to add. I do not feel that I ought to back up the term too strongly, yet I think we should have some other term to denote this condition. Heart failure is an opprobrium. If we amputate a man's leg and the man dies we should not say that he died from the amputation of that leg. The way to treat medical shock is to prevent it in much the same way that we prevent surgical shock; there is a prevention for medical shock as there is for surgical shock. I think the term medical shock will help us in making up our statistics.

THE SPREAD OF TUBERCULOSIS BY COUGHING.*

L. NAPOLEON BOSTON, A.M., M.D.

Bacteriologist to the Philadelphia Hospital; Demonstrator-in-Charge of the Clinical Laboratories of the Medico-Chirurgical College.

PHILADELPHIA.

The general opinion held by the medical profession at large has been that tuberculosis is disseminated chiefly by sputum, pus from tuberculous ulcers and sinuses, and from the dejecta of the bowel in persons or in animals suffering from tuberculous enteritis; these substances, from whatever source, becoming dry and later pulverized; they, together with their tubercle bacilli, are carried about by the currents of air. Such dust is commonly agitated by sweeping and dusting of carpets, rugs and furniture in rooms previously occupied by tuberculous patients. Indeed, the investigations of Cornet[1] go far to corroborate this popular belief.

Cornet showed that dried sputum—dust—remained dangerous for months. He collected dust from the floors, walls and furniture of rooms previously occupied by persons suffering from pulmonary tuberculosis in various prisons, hospitals, asylums, and private dwellings, and, inoculating animals with such dusts, he determined the presence of virulent tubercle bacilli. Of the 118 samples of dust collected from the rooms of phthisical hospital patients, 40 were found capable of producing tuberculosis in animals by inoculation. Dust collected from 21 medical wards was also proved to contain living virulent bacilli in 15 of such samples. In one instance the dust was found to be infective six weeks after the death of the patient. Cornet,[2] to prove further the infectiousness of such dust, shook in a room a carpet infected with tuberculous sputum dust, and forty-eight hours later placed in this room 48 healthy guinea-pigs, of which number 46 developed extensive lesions of tuberculosis. Attempts to infect animals by the blowing of tuberculous sputum dust was attended with negative results.

Heron, in the City of London Hospital, and Hance,[3] in the Adirondack Cottage Sanitarium, do not find tubercle bacilli common in the dust of these institutions, being found in but 1 of the 17 specimens studied. These and other investigators have shown that the air and dust of certain institutions and dwellings occupied by consumptives were contaminated with tubercle bacilli, and this, in connection with the clinical fact that healthy persons who occupied such places were likely to develop tuberculosis, furnished additional support to the belief that infection took place through the respiratory tract; and that the sputum was the chief source of danger, seemed evident.

---

* Read at the Fifty-second Annual Meeting of the American Medical Association, in the Section on Practice of Medicine, and approved for publication by the Executive Committee of the Section: Frank Billings, George Dock and J. M. Anders.

The swallowing of bacilli from the mouth or upper respiratory tract has long been regarded as a dangerous procedure, as has also been the feeding of infants on milk from tuberculous cows, as shown by Cornet.[4] Klebs, Gerlach, and others have shown that milk from tuberculous cows is capable of producing the disease in animals fed upon such milk. Further, it has been shown by Klebs, Parrot, Aufrecht, Chauveau[5] and other observers, that if the sputum from consumptives be incorporated with the food for susceptible animals, such animals develop tuberculosis. It will suffice to make mere mention of direct infection, since such instances are comparatively rare, and certainly occupy a small percentage of all tuberculous processes.

Flugge[6] was probably the first to consider the question of the dissemination of tubercle bacilli by coughing. "It is not at all proved that inhalation of dried sputum dust can produce tuberculosis in healthy men. If there is infection in healthy men this can be produced either by contact or inhalation, not so much by dried dust as by sputum which is spread in the air in finest drops in coughing." This spray composed of droplets containing tubercle bacilli may float in the air for some time, and be carried by fine currents about the room. Flugge regards this spray to be the true cause of infection, and to support this view he compares the results obtained by spraying dried sputum and moist sputum into cages occupied by experimental animals, in which cases the latter only gives positive results. He calls attention to persons who cough with closed lips, and to those who allow the mouth to remain open while coughing; of these, the latter class only is regarded as dangerous, and this danger is obviated by the avoidance of hard coughing, or the application of a handkerchief to the mouth while coughing.

Laschtschenko continued Flugge's experiments by demonstrating that this spray containing bacteria was produced by loud talking, coughing and sneezing. For this purpose the bacillus prodigiosus was added to the mouth fluids, after which agar-agar plates were exposed in various portions of the room, and in this way the bacilli were recovered at a distance of ten meters from the patient after hard coughing. Tuberculous patients were permitted to cough into a glass box, in a distant portion of which a bowl containing distilled water was placed. This water, after being exposed to the spray emitted by an indefinite number of coughs, often contained tubercle bacilli. Glass plates were exposed one-half to one meter (19.75 to 39.50 inches) distant from the patient's mouth, when he was directed to cough against them, and by the staining of such plates tubercle bacilli were occasionally found.

J. J. Curry,[7] at the suggestion of Prof. Edwin Klebs, studied 12 cases of pulmonary tuberculosis, in all of which the sputum contained tubercle bacilli. Examination of the mouth fluids at various hours during the day, by staining, resulted in the detection of tubercle bacilli in 9 of the cases; bacilli were most plentiful during the morning hours and after a paroxysm of coughing. In 6 of these 9 positive cases, it was extremely difficult to demonstrate the bacilli in the mouth fluids. Glass plates were suspended before the patients, at distances of from one to three feet, during coughing. These plates presented two varieties of spray, one composed of very fine drops, the other of larger drops, one to five millimeters in diameter. In these larger drops were the tubercle bacilli found, 28 being the largest number noted in the large drops. By the staining of these plates Curry obtained positive results in 50 per cent. of cases.

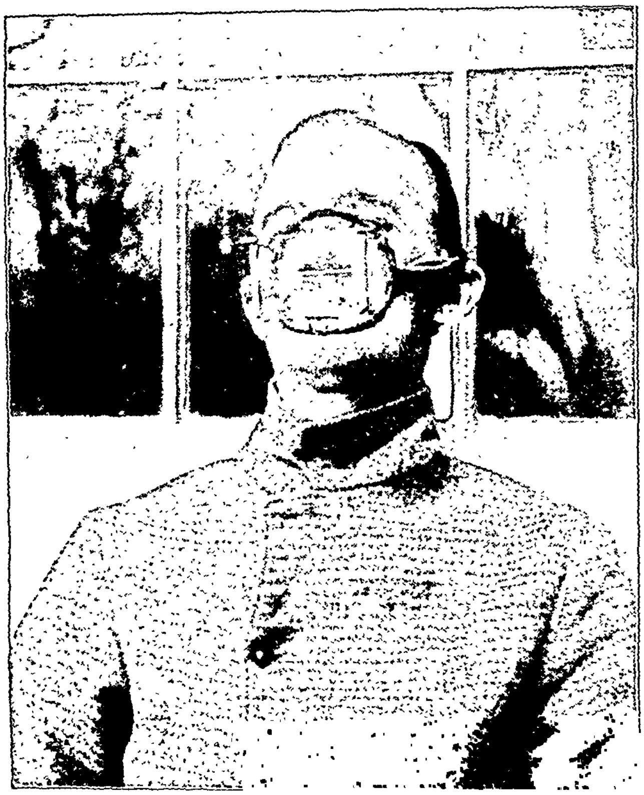
W. Goldie,[8] assisted by Dr. Southerland and Mr. Young, repeated the experiments of Flugge, his assistant Laschtschenko, and Curry. They confirm the statements made by Laschtschenko by using an emulsion containing the bacillus prodigiosus in the mouth; they found that most colonies developed on plates exposed ten feet distant from the patient and at an elevation of five feet, during coughing, these findings being influenced by vigorous coughing and by currents of air. It was further shown that plates were infected at a distance of ten feet by laughing, six feet by loud talking, three feet by ordinary talking, while deep breathing seldom infected plates, even at a few inches from the mouth. During ordinary talking for two minutes, 90 droplets fell on a four-inch glass plate placed eight inches from the speaker, each droplet containing bacteria. Clean glass plates were held six inches from the mouths of phthisical patients while coughing, for twenty-four hours, and when stained by carbol-fuchsin gave positive results, as follows: 60 per cent. of all cases; 60 per cent. where cough was accompanied by expectoration; 33 1-3 per cent. where cough was not accompanied by expectoration; 28 per cent. where plates were used during a single coughing in the morning, and 14 per cent. when used during the evening. The droplets varied from a few (50 microns) to many millimeters in diameter, and were composed largely of thick mucus and leucocytes. Single fields, under the oil-immersion lens, were seen to display from 125 to 200 tubercle bacilli. The mouth fluids were rarely found to contain bacilli, and only when the sputum was noted to be profuse or liquid.

M. P. Ravenel[9] collected, on pieces of soft pine wood, the spray thrown out by tuberculous cows in coughing, by placing the wood near the bottom of a nose-bag which the animal wore for a variable time. In cases where only a small amount of spray had collected, this, when transferred to cover-glasses and stained, was always found rich in tubercle bacilli, and it was possible to demonstrate the bacilli in the spray from every tuberculous animal studied. Of 22 guinea-pigs inoculated with portions of this spray, 11 became tuberculous. Guinea-pigs were exposed to the breath of tuberculous cows, but in no instance did infection occur. Noteworthy is it that these cows were not all in the later stages of the disease, one living for more than two years after the experiments were made.

The causes which prompted me to investigate the degree with which tubercle bacilli are disseminated by coughing were as follows: 1, from the mouth of an inmate of the Philadelphia Hospital who presented the conditions common to advanced phthisis, I noticed that fine droplets of sputum were ejected with each cough, and 2, I observed that coughing was often excited by eating, not only in patients confined to their beds, but also in those able to walk to the dining-room. It appeared to me that if this fine spray contained tubercle bacilli, when produced in such quantities in the dining-room where it must of necessity fall upon the food to be eaten by others, as well as those producing such spray, furnished a potent factor in the dissemination of tuberculosis, and possibly explained why patients in the early stage of the disease did not do well in this institution, where every possible attention is given to ventilation, light, and the disinfection of sputum.

METHOD OF COLLECTING SPRAY.

This was accomplished by means of a mask (Figs. 1 and 2). It was made from German silver wire, one piece of which is molded to fit the face, resting on the nose, cheeks and chin. To obviate any irritation to the patient, this portion was covered by a piece of rubber tubing. Suspended from this wire is a second oblong portion provided with two lateral grooves, which serve to accommodate two microscope slides. When the mask is in position the slides are held directly in front of the mouth and nose, at a point three inches distant from the lips. The mask is held in position by an elastic band which passes above the ears and over the occiput.



Patients were allowed to wear the mask with the clean slides in position for from one to one and a half hours, during the day when they were apt to cough least and were instructed to remove it during a paroxysm of coughing. It was never worn during the morning or evening; the object being not to collect on the slide the spray produced by vigorous coughing, which had already been studied, but to determine whether or not consumptives emitted a fine spray, when talking, laughing, clearing of throat or by their characteristic hacking, that was in any way dangerous to the health of their associates.

Fifty patients, 34 males and 16 females, all of which presented unquestionable evidence of either pulmonary or laryngeal tuberculosis and in whose sputa tubercle bacilli had been found, were made to wear the mask as above described.

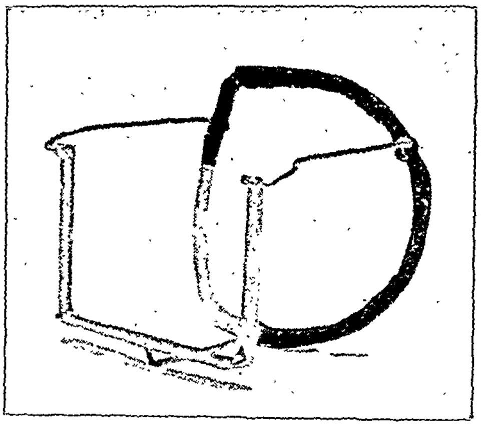
NAKED EYE APPEARANCE OF SPRAY.

This varied greatly and since patients were cautioned not to encourage coughing, no satisfactory explanation for such changes was noted. Certain slides displayed many droplets, varying from the size of a pin's point to that of its head. Others showed few droplets, while a third variety presented an evenly-spread film, very thin, covering the entire slide and seldom showing any distinct droplets.

MICROSCOPIC STUDY.

Specimens were fixed and stained by carbol-fuchsin and Gabbett's acid blue solution. Of the specimens collected from 50 patients, those from 49 were found to contain bacteria—the diplococcus and the streptococcus being the most constant, yet baccili and clusters of cocci were not unusual. A single minute droplet often contained organisms of each class.

Of these 50 specimens, 38 were found to contain tubercle bacilli in variable numbers, four to six bacilli being the smallest number found in any specimen, and many of the specimens, under a 1/12 oil-immersion lens, showed fields of bacilli too numerous to be counted. In fully one-third of the positive cases the bacilli were very numerous. In one of the specimens where I hunted for fully one hour and passed the specimen as one not containing tubercle bacilli, Dr. W. J. Hawke, resident pathologist, in studying this slide later, found a droplet containing more than forty bacilli. I am further indebted to Dr. Hawke for his untiring interest and valuable assistance rendered.



Among other findings were large and small squamous epithelium and occasionally very small epithelial cells more or less intimately connected with thick mucus and leucocytes. The tubercle bacilli were commonly associated with these elements, but were occasionally found singly or a number of bacilli without any other elements in the field.

CONDITIONS INFLUENCING THE SPRAY.

From patients showing tubercular laryngitis and from those who talked loudly, or who were frequently clearing their throats, the most spray was found. In patients very weak, speaking only in a whisper, scarcely any spray collected on the slide and this seldom contained bacilli. Men wearing heavy mustaches ejected no spray on the slide until after the mustache was held from falling over the mouth. Coughing with the mouth open must necessarily favor the production of the spray.

Of the 12 negative cases, these explanations are given: Sputum from 3 such patients contained only few bacilli and these were not found until after several examinations, none being found at the time when the specimen slides were collected. Another showed no bacilli in his sputum, yet autopsy revealed cavity formation. Three were extremely weak and did not talk while wearing the mask. The remaining 5 presented marked sprays containing many bacteria; yet careful examination failed to reveal the presence of tubercle bacilli.

The detection of the bacilli in these fine droplets of the spray was greatly facilitated by the use of a low power lens for the purpose of locating such droplets; after which a 1/12 oil-immersion lens was used. Droplets not perceptible to the naked eye were often found in this manner, and such minute particles not infrequently contained tubercle bacilli; at times they were present in great numbers. By the employment of these methods, it can be stated with safety that the finding of tubercle bacilli in the spray emitted by consumptives during the act of coughing, sneezing, laughing, and talking, is not attended with greater difficulties than is the finding of the bacilli in the sputum of patients early during the course of the disease.

VALUES IN DIAGNOSIS.

These are doubtless limited. However, from the extreme difficulty one always meets in eliciting satisfactory physical signs from the chest examinations of the insane, and since we are seldom able to collect the sputum from such patients, it would appear that if they be carefully guarded by the attendants, this method of collecting their sputum for clinical study should have at least a limited field of usefulness. In nearly all instances a slide could be placed in a forceps and then held by an attendant before the patient's mouth during one or more vigorous coughs. In one instance, that of a colored female, aged 19, few bacilli were found after wearing the mask for one and a half hours, during which time she did not cough, while the spray from a single cough during a paroxysm showed many bacilli. Where the mask was worn for ten minutes during such periods great numbers of bacilli were found.

Children, likewise, seldom expectorate and a mask could readily be adjusted to the face of any child, and by carefully instructing the nurse, specimens could be collected during the acts of coughing or crying. This, as well as its value in the clinical study of the insane, must be further tried, and estimated only from the results obtained.

HYGIENE.

Now that it is shown that the secretions of the mouth and respiratory tract are atomized and given off in the form of a fine spray, in both health and disease, and that this spray contains bacteria and other cellular elements known to be common to such secretions, it is reasonably fair to suppose that many other diseases are conveyed by this medium, and that the work accomplished through the study of consumptives is but a step in a direction which bids fair to modify, in a measure at least, the hygiene of infection. Conditions affecting these organs and consequently their secretions must of necessity be spread in this way; especially is this true of diphtheria, tonsillitis, and possibly other conditions, the etiology of which is not definitely known, such as smallpox, measles, scarlet fever, whooping cough, mumps, etc. It further furnishes additional cause for the rigid disinfection, now universally carried out, in connection with all cases known to be infectious in character.

Droplets alighting on clothing must serve as a favorable means to convey disease from house to house; and that man may become infected by the spray thrown off by horses, cows, and other domestic animals suffering from glanders, tuberculosis, influenza and similar affections, appears highly probable.

SURGICAL VALUE.

To repeat, "experiments show that during ordinary talking for two minutes, ninety droplets may fall in a four-inch circle at a distance of eight inches, each of these droplets containing from dozens to thousands of bacteria." (Goldie). At first this would tend to convey the impression that the danger of infecting open wounds during an operation by the sprays produced by the talking of the surgeon or any of his assistants is extremely great, and this would doubtless be true where any person assisting in the operation is suffering from either an acute or chronic infection of the mouth, throat, or respiratory tract. A fact ever to be borne in mind is, that in health this spray may contain great numbers of bacteria; yet few, if any, such organisms possess the properties necessary to infect man, even when introduced into an open wound. The advisability of all persons being provided with a mask of gauze on entering the operating room, to prevent all possibility of their contaminating the air of the room, would appear from a bacteriologic standpoint to be a rational procedure; yet before this precaution can be urged, it, too, must be tried by the surgeon, and shown to lessen the number of cases of infection for which at present no ascribable cause is given.

TREATMENT OF CERTAIN FORMS OF CANCER BY THE X-RAYS.

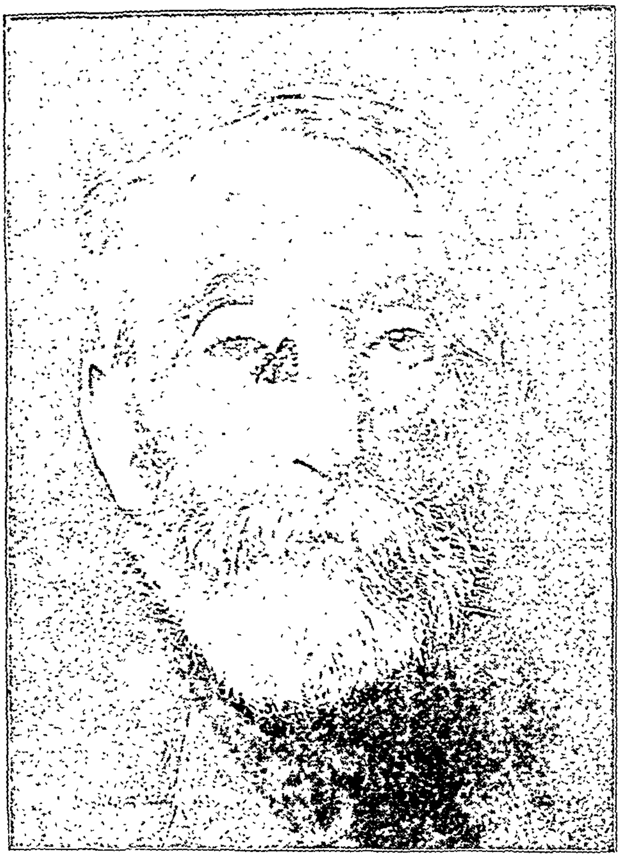
FRANCIS H. WILLIAMS, M.D.
BOSTON, MASS.

It is well recognized that cancer is on the increase, and reliable statistics made in various countries and extending over periods of years prove that the rapidity of this increase is surprisingly great. Any method of successful treatment, even though it may be limited in its application to certain forms of this disease, will prove to be a great boon to humanity. Further, as is natural with the advance in the application of science to medicine, the opportunities for the irregular practitioner will be curtailed.

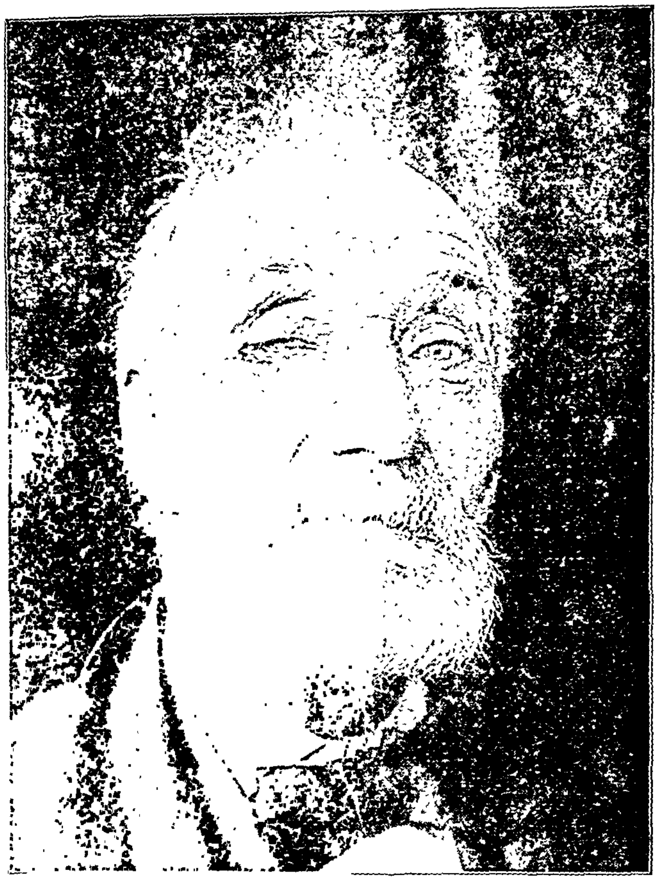
Although I shall refer to but few of the cases I have treated, I hope to present enough to have the reader share my opinion, namely, that in the x-rays we have an agent which causes superficial external forms of cancer to heal; and this may be done without pain to the patient.

From the standpoint of treatment by the x-rays, cancers may be divided according to their position into external and internal forms. Of the internal cancers

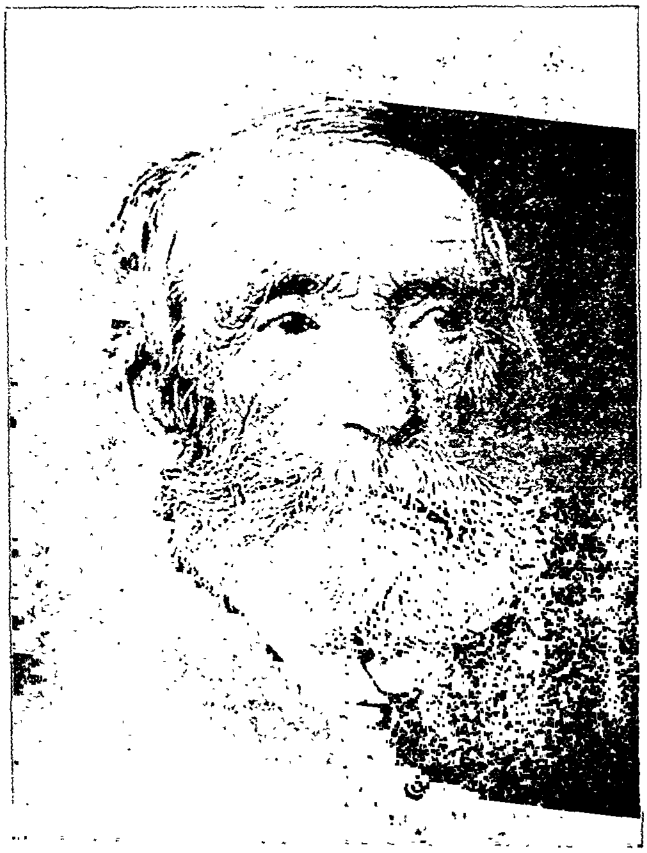
I will not speak at the present time, as it seems better to wait until I have had more experience with them, but will take up the external forms, which thus far appear most suited for treatment by this new method. I think the subject can be best presented by a brief report illustrated by photographs of some of the cases that have been or still are under my care.



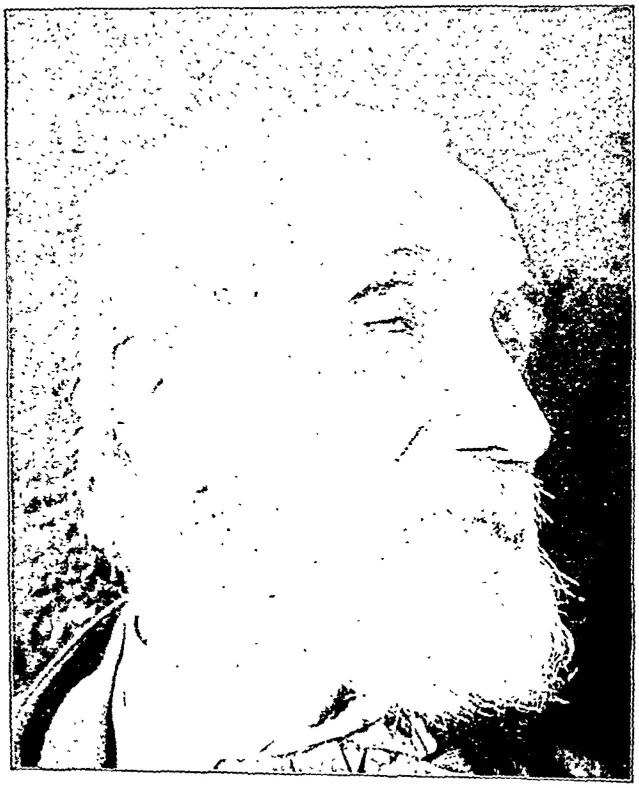
Rodent Ulcer. Before treatment.



This case shows how harmless the X-rays may be, when carefully used, even near the eye.



Rodent Ulcer, duration fifteen years. After treatment by X-rays. The ulcer, which was a deep one, healed by first filling up from the bottom and then closing over. The healing went on without pain or inconvenience to the patient.



By further treatment by the X-rays this has improved more than is shown in these photographs.

The diagnosis in all the cases which I have treated, except one, which was undoubtedly a rodent ulcer, has been made by means of the microscope. They include epidermoid cancers, typical epitheliomas, and rodent ulcers, and also cases which had the clinical appearance of beginning cancers, but which under the microscope were found to be plasmoma, or simply cases of ulceration and necrosis, or chronic inflammatory tissue.

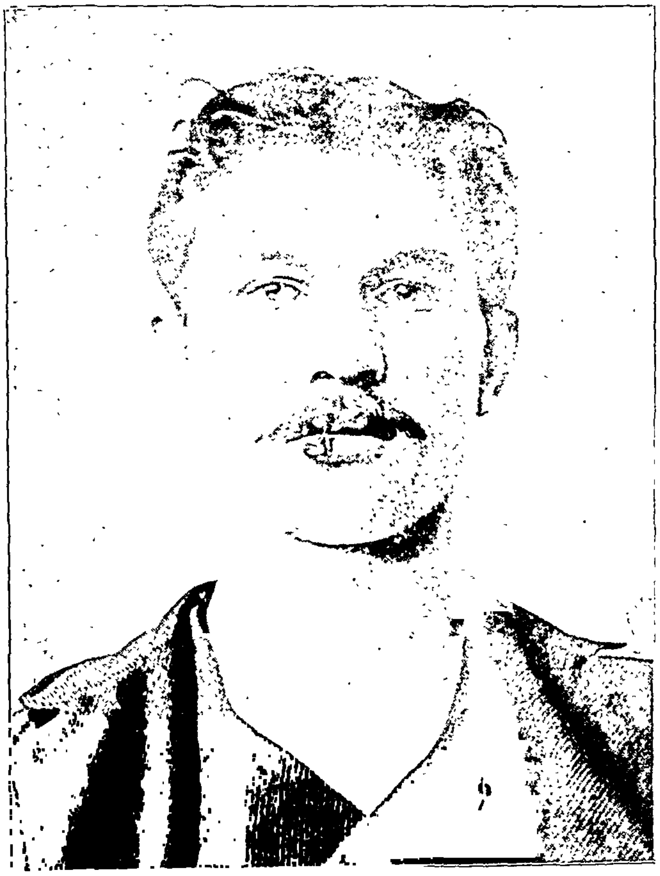
As the first cases of cancer yielded to treatment by the *x*-rays, I became sanguine enough to state to new patients that this method would cause the growth to disappear if it were cancerous in nature; if, however, the microscope showed that it was not of a serious form, I felt obliged to give a doubtful prognosis. But further experience teaches me that those growths which clinically resemble beginning epitheliomas also yield to treatment by the *x*-rays, and the indication is that we have in this new agent a useful therapeutic measure for most—possibly for all—forms of external new growths, except perhaps those due to syphilis.

From the fact that the *x*-rays are useful in treating a variety of abnormal conditions of the skin, or parts near by, it would seem that their local action must stimulate healing or that these abnormal conditions are due to organisms to whose life or life conditions the *x*-rays are inimical.

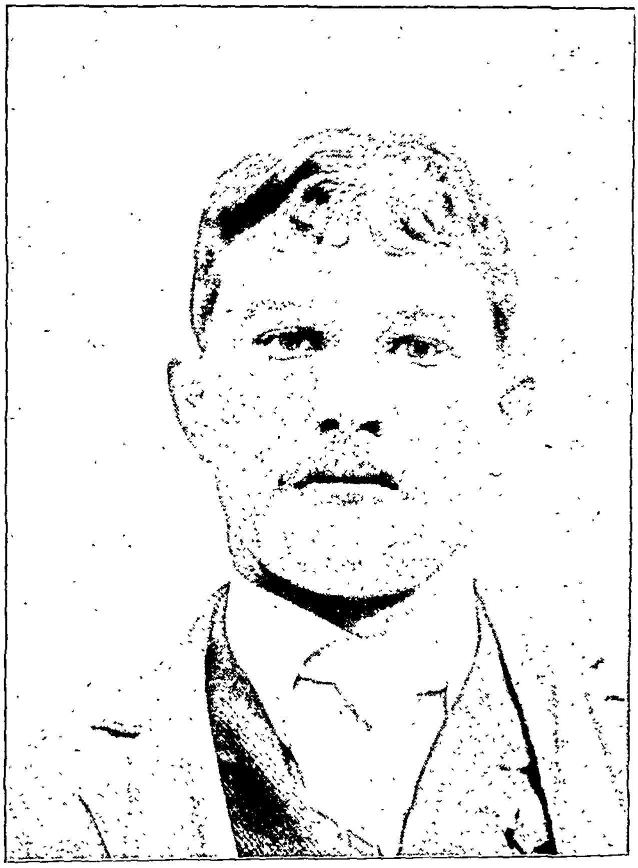
Thus far, all the forms of superficial growths mentioned above have yielded to treatment by the *x*-rays. That is to say, in every case, with the exception of one of rodent ulcer where the treatment was pursued for a short time only—and of course should not be included—the new growth has disappeared, or is improving under treatment. It would therefore seem that we have undoubtedly for external growths, a new, painless and harmless form of treatment, and also one which yields excellent cosmetic results. Whether these new growths will return within two or three years, can only be determined by time; but if there should be a recurrence, treatment can again be instituted.

This form of treatment also has the advantage of causing a diminution, or cessation of the pain resulting from the new growth, and the disappearance of foul odors from discharging ulcers. Further, it should encourage patients who have suspicious growths to consult a practitioner in regard to them at the very earliest moment, and not delay, as many are inclined now to do, through dread of the knife, until the growth has attained greater size and caused more inconvenience.

Great care is necessary to carry out the treatment properly. First, the surrounding parts should be protected from the action of the rays, and second, the treatment should not be pursued so vigorously as to cause an *x*-ray burn. While in making the ordinary *x*-ray examinations—as, for example, examining the heart and lungs—there is no risk whatsoever to the patient, of an *x*-ray burn, in treating cases of cancer it is necessary to have the tube so near the patient that, in unskilful or inexperienced hands, a burn may result. This might be a serious matter, as such burns yield only slowly, and might cause disfigurement. I do not mean to suggest that an *x*-ray burn is a necessary result of the treatment in external cancers; quite the contrary, for all of my cases have been treated without the occurrence of this accident, but I desire to emphasize the necessity for care.



Epidermoid Cancer of Lip.



Epidermoid Cancer of Lip. After treatment by the X-rays.

The details of treatment and the various precautions to be taken I have considered fully in my book on "The Roentgen Rays in Medicine and Surgery," and therefore will not present them here, as it would occupy too much of your time.*

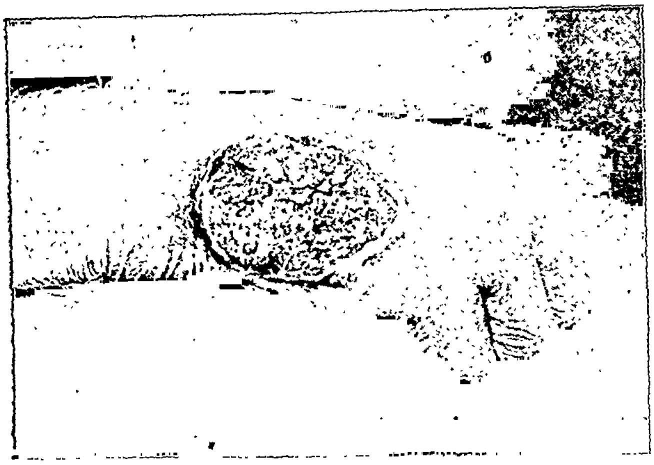
In the following cases from which these photographs were taken, the microscopic examinations were kindly made by Dr. F. B. Mallory, assistant pathologist of the Boston City Hospital.

The first is an epidermoid cancer of the lip, and the photographs show the results obtained. The diminished amount of hair seen above the lip is not due to the *x*-rays, but to the fact that the patient shaved off his mustache after the first two photographs were taken, but let it grow again shortly before the last two were made.

The second case is an epithelioma of the eyelid, which was treated without causing the slightest trouble in the eye and without interfering with the work of the patient. Treatment was suspended for a time in this case, owing to my absence, but the improvement, already begun, continued during this interval.

The third case is that of a rodent ulcer on the side of the nose and cheek. The photographs, taken before and after treatment respectively, need no comment. They speak for themselves, like those already shown.

The last case that I shall take up is an epithelioma of the right hand, and is improving, but still under treatment. The growth was cauliflower-like in form, four centimeters wide by seven long, with raised, indurated edges. The photograph shows the condition before treatment was begun. In inoperable cases, such as those of the orbit, the tongue or the larynx, the *x*-rays should be tried in the most thorough manner.



Typical Epithelioma of Hand, before treatment by X-rays. This was 4 cm. wide and 7 cm. long.

The external growths that I have treated with good results have varied in the length of time they have existed from a few months to twenty years. This fact shows that even when the growth is of long standing the *x*-rays are of assistance.

It has been known for many years that these growths yield to treatment by various forms of caustics, so that if the *x*-rays simply act as a new form of caustic, some of the older forms might rather be employed; but my experience shows that we have in the *x*-rays a therapeutic agent that is novel in its mode of action, and that these growths disappear without a burn being produced.

The advantages of this new method may be summed up as follows: The treatment causes no pain; healing is produced without creating a burn; some cases improve after a certain number of sittings without further renewal of the treatment; the treatment can be carried out without interfering with the work of the patient.

The disadvantages are that the necessary apparatus is expensive and difficult to use; that great care must be exercised when the *x*-rays are employed as a therapeutic agent, and that the treatment must often be continued for some weeks.

THE RELATION OF UNBALANCED PHYSICAL DEVELOPMENT TO PUBERTAL MORBIDITY AS SHOWN BY PHYSICAL MEASUREMENTS.*

W. S. CHRISTOPHER, M.D.
Professor of Pediatrics, College of Physicians and Surgeons.
CHICAGO.

The measurements upon which this paper is based were made by the Child Study Department of the Chicago Public Schools, under my direction as Chairman of the Department. The gentlemen composing this department are Mr. F. W. Smedley, Director, and Messrs. C. C. Krauskopf, Daniel P. McMillan, and C. Victor Campbell, assistants. These gentlemen are all thoroughly equipped for the work, and large experience in making measurements has made them exceptionally accurate, and this skill on the part of the observers gives great weight to the observations. I wish to acknowledge particularly my indebtedness to Mr. Smedley, who jointly with me has discussed every phase of the work done by the Department, and every detail of its official publications.

The tables are based upon the measurements of 6259 children, 2788 boys and 3471 girls. Seven measurements were made of each child, except that no ergographic work was done with children under 5 years of age.

The children examined were all pupils in the Chicago Public Schools and were mainly the children of American parents in comfortable circumstances, the schools where the examinations were made being selected with reference to these points. In each school, however, all pupils were examined. These measurements include net stature, height sitting, weight with ordinary indoor clothing, endurance as measured by the ergograph, strength of grip of the right hand, strength of grip of the left hand, and the so-called "vital capacity" or volume of expired air. The methods of making these measurements, and the instruments employed were described in my paper "Measurements of Chicago School Children," read before this Society last year, and therefore need not be repeated here.

Table 1 gives the norms for each sex, in each of the several measurements, at each of the ages from 4 to 21 inclusive. These norms have been determined by averages, the actual computations being made with the aid of an adding machine. The table also gives the average ages and the number of children of each age examined. The norms given last year were medians, and a comparison of the two tables will show that they differ but slightly from each other, except at ages at which the number examined was considerably increased, and even in such cases the differences are really not great, the greatest difference in stature, for instance, which is found being only 13 mm. The close coincidence of these tables measures their approximation to the truth.

---

* The cuts shown herewith are inserted by permission of the MacMillan Company.

* Read before the American Pediatric Society, at Niagara Falls, May 29, 1901.

At the time of making the measurements, the birthday of each individual was recorded, and from this the exact age in years, months and days was computed. All those having the same age *in years* were grouped together, and the averages of the exact ages, as well as the averages of the several measurements were calculated. As will be seen from the table, where the ages are expressed in years, months and days, the average ages approximate the even half years, but differ from them more or less, and in both directions. By determining the exact number of days between consecutive ages, figures were obtained which upon division into the corresponding differences in the other measurements gave the average daily increments of those measurements at the several ages. With the aid of these factors the norms were reduced to the integral years and half years. These norms we have called birthday norms, and they are given in Table 2. Table 3 gives the average monthly increments of the several measurements at the different ages. With the aid of these monthly increments and of the table of birthday norms, the average normal measurements of a child of any age can readily be computed.

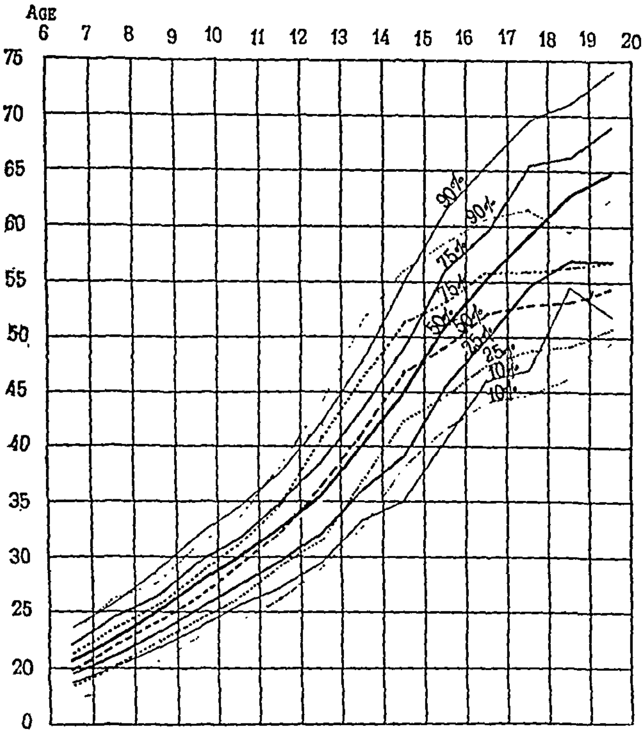


CHART 1.—Weight of pupils distributed into percentile groups. The dotted lines represent the girls; the solid lines the boys. Based on data in Table IV.

Table 4 is based upon the distribution of the children measured into percentile groups. Thus, of all the 4-year-old boys measured as to stature the shortest was 86 cm. tall; 10 per cent. were below 96 cm.; 25 per cent. were below 98 cm.; 75 per cent. were below 104 cm.; 90 per cent. were below 107 cm.; and the tallest measured 116 cm. On such basis this Table 4 has been computed, the distribution into percentile groups being given for each of the several measurements taken, for each age and sex. As originally printed in the second report of the Child Study Department, this table contains some errors. These errors have been corrected from the original records of this Department for the table here presented, and the table will be found correctly printed in the Forty-sixth Annual Report of the Chicago Board of Education, which will appear soon. The items of this table which relate to weight are shown graphically in Chart 1.

Table 5 shows separately for each sex and for each of the physical measurements taken the following points: 1, the special measurement under consideration, at the beginning of each year, as shown in the table of birthday norms; 2, the increase in that measurement found at the beginning of the next year, or the increment during the year; 3, the percentage that this increment is of the measurement at the beginning of the year during which it has occurred. These percentages of annual increase are shown graphically in Charts 2, 3 and 4.

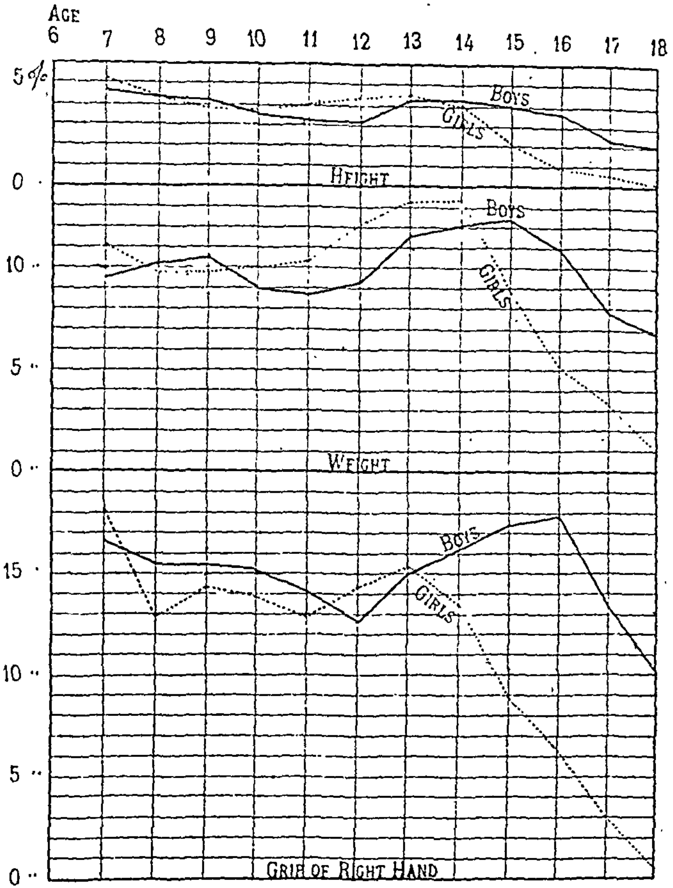

CHART 2.—Rate of annual increase in stature, weight, and strength of grip. Based on data in Table V.

An examination of these charts reveals some important truths of child life. First directing attention to the chart of annual percentage increase in height of boys, it is seen that the general trend of the curve is downward. From 7 to 9 the line is practically straight and if extended will be found to coincide with the line from 17 to 18. But from 9 to 12 the curve drops below this general trend, indicating a period of relative quiescence in growth. From 12 to 17, however, it rises above the line of general trend and indicates a period of accelerated growth. The curve for girls shows a less well-marked quiescent period, a better marked and shorter rise, and a

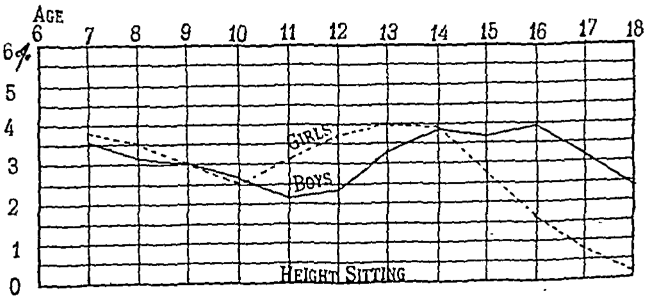

CHART 3.—Rate of annual increase in height sitting. Based on data in Table V.

greater and more rapid decline. In each of the other measurements it is seen that there is a sharp rise commencing at 11 or 12 in boys, and generally a year earlier in girls, and in general following the conditions noted with regard to stature. It does not seem justifiable to attempt an interpretation of the minor features of the curves, but the following seems to me to be fairly shown:

There is an exaltation of life processes at the pubertal period which finds its expression not only in an increased rate of growth, but also in the development of physical power. This exaltation is preceded by a period of relative quiescence. In the sexes this exaltation differs in that it commences earlier and has a shorter duration in girls than in boys; moreover, it is more marked in girls than in boys in weight and in stature, and less marked in measurements involving physical power.

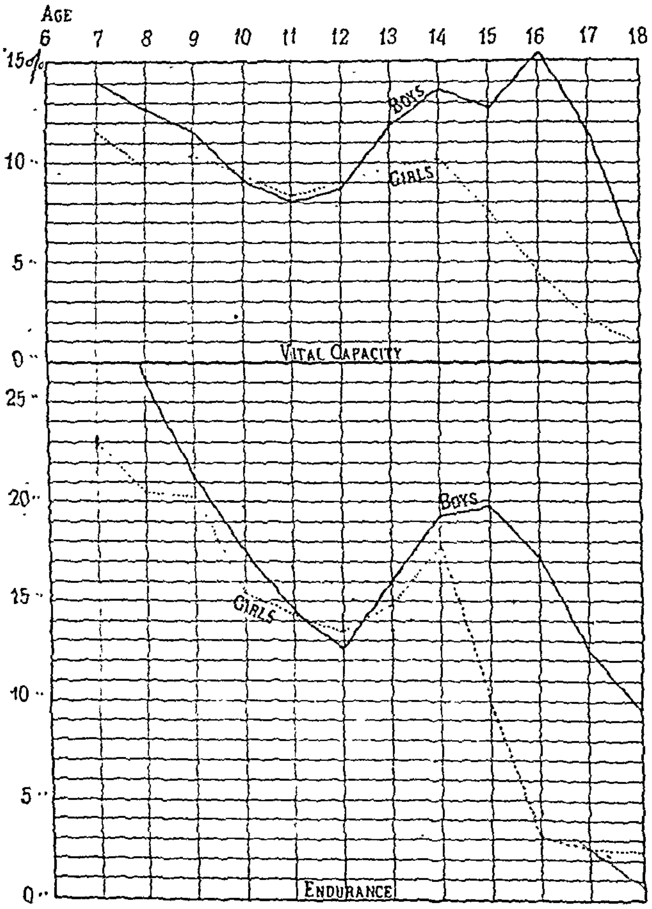

CHART 4.—Rate of annual increase in vital capacity and endurance. Based on data in Table V.

This pubertal exaltation has often been shown before as to height and weight, but I am not aware of any other investigation which shows it to be true of so many physical measurements.

In Table 1 the averages of each measurement for each age are given. The curves *representing* these averages are necessarily lines, but it is certainly true that there is a range of variation about *these lines which* must be considered normal, so that normal measurements should be represented by a belt rather than a line, for certain purposes at least.

Tables 6 and 7 and the *corresponding* charts show an attempt to investigate the nature of *this belt. For* this purpose the tables of percentile groups are utilized. Tables 6 and 7 are classified with reference to the sexes, ages, and the several physical measurements made. Each section of these tables *gives* four columns. The first column *gives the difference in the measurement*, or the range of the measurement, between the 10 per cent. group and the average given in Table 1. The second column gives the range between the average of Table 1 and the 90 per cent. group. The third column gives the range between the 10 per cent. and the 90 per cent. groups, or the range of measurement of the middle 80 per cent. of the children. The fourth column gives the difference in measurement between the 25 per cent. and the 75 per cent. groups, or the range of the middle 50 per cent. of the children. Columns 3 and 4 are graphically represented in Charts 5 and 6, while columns 1 and 2 are graphically represented in Charts 7 and 8.

From examination of Chart 5, which shows the absolute range of measurement of the middle 50 per cent. *and the middle 80 per cent.* of boys, it is clear that there is a general pubertal increase in *the range of the measurements* of both groups of the children, and that this increase in range is more marked in the larger than in the lesser group. Chart 6, relating to girls, shows these facts with reference to girls rather more clearly than they are shown with boys. Moreover, the pubertal increase in range occurs earlier in girls, as was to have been expected.

It is still necessary to determine how the ranges of measurements are distributed with reference to the average measurements at the several ages. This is shown in *Charts* 7 and 8, which show that in both sexes the *range is distributed* almost uniformly about the average line. While puberty is a period of great *exaltation of life processes*, Charts 5 to 8 show that it is also a period of great individualization. It is a time when the weak fail and the able forge to the front.

It is well known that mortality is less *at puberty than* at any other period of child life, and Axel Key has shown that the morbidity is high at this period. In my judgment, the explanation of the low mortality will be found in the laws illustrated in Charts 2, 3 and 4, while the conditions shown in Charts 5, 6, 7 and 8 will be found to have an important bearing upon the causation of the high morbidity.

The neuroses, psychoses, neurasthenias, cardiopathies, deformities and anemias of puberty are the principal morbid manifestations of the physical, intellectual and emotional turmoil which characterize the period.

At first thought it would seem that the subnormal portion of the belt shown in Charts 5 to 8 would contain the children who present the pathologic conditions. This, however, is not the case. It is the great range of the physical measurements of this period which *permits* of the existence in the child of an *enormous* lack of balance *in the physical* measurements, and it is this *condition* of lack of balance which gives rise to the morbid manifestations. For *instance, if in a child the normal exaltation* of height and weight, or of either, passes beyond, or taxes heavily, *the capacity* of the organs of nutritive supply, *the child* is on the borderland of physical insolvency, and any excessive voluntary expenditure of energy may be followed by morbid symptoms. In one case under my care (see Case 1), a neurotic boy, who increased in weight with great rapidity, had an epileptic convulsion follow every instance of excessive exertion. One such seizure followed a 20-mile bicycle ride, and another a game of baseball. He was practically free from convulsions as long as he refrained from unusual expenditure of energy. Rapid increase in stature, associated with deficient nutritive supply, is commonly productive of stoop and muscular atrophy, and is usually accompanied with rapid and irregular pulse, and manifestations of fatigue and neurasthenia. It is in such cases also that the dilatation of the heart, well known to occur at puberty, is to be found. These cases require for their proper management rest, improvement in general nutrition, and the much-despised shoulder braces.

In general it may be said that an important factor in pubertal morbidity is unbalanced physical development.

The great range of pubertal measurements which makes possible the extensive unbalanced physical development of the period, being physiologic, is directly traceable to heredity, but there are factors other than heredity which assist in the production of the actual lack of balance itself, and which must be taken into consideration in determining the management of individual cases. These factors are nutrition and the physical and mental activities of the child.

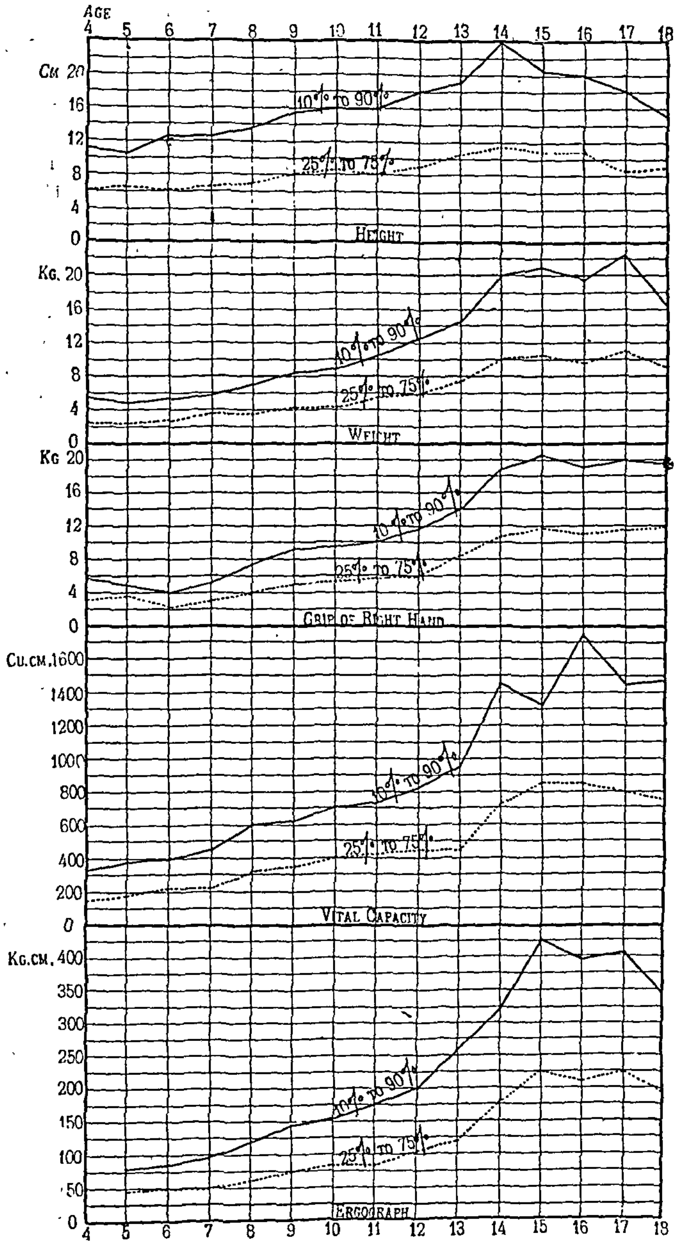

Chart 5.—Absolute range of measurements between percentile groups—Boys. Based on data in Table VI, columns 3 and 4.

I present here a plan for the investigation of cases of unbalanced physical development. The first three divisions of this plan are in general etiologic, and the last three are in general resultant, but such a classification would not be strictly accurate, for examination will show that some of the factors of the second group bear at times etiologic relations to factors in the first group, which means that vicious circles exist and that some conditions mutually augment each other.

PLAN FOR INVESTIGATION OF CASES OF UNBALANCED PHYSICAL DEVELOPMENT.

1. Hereditary tendencies and influences.
2. Nutrition. *(a)* Food supply (quantitative and qualitative). *(b)* Condition of nutritive organs, viz.: gastroenteric tract and liver. *(c)* Condition of the blood. *(d)* Type of the general metabolism. *(e)* Condition of the eliminating organs.

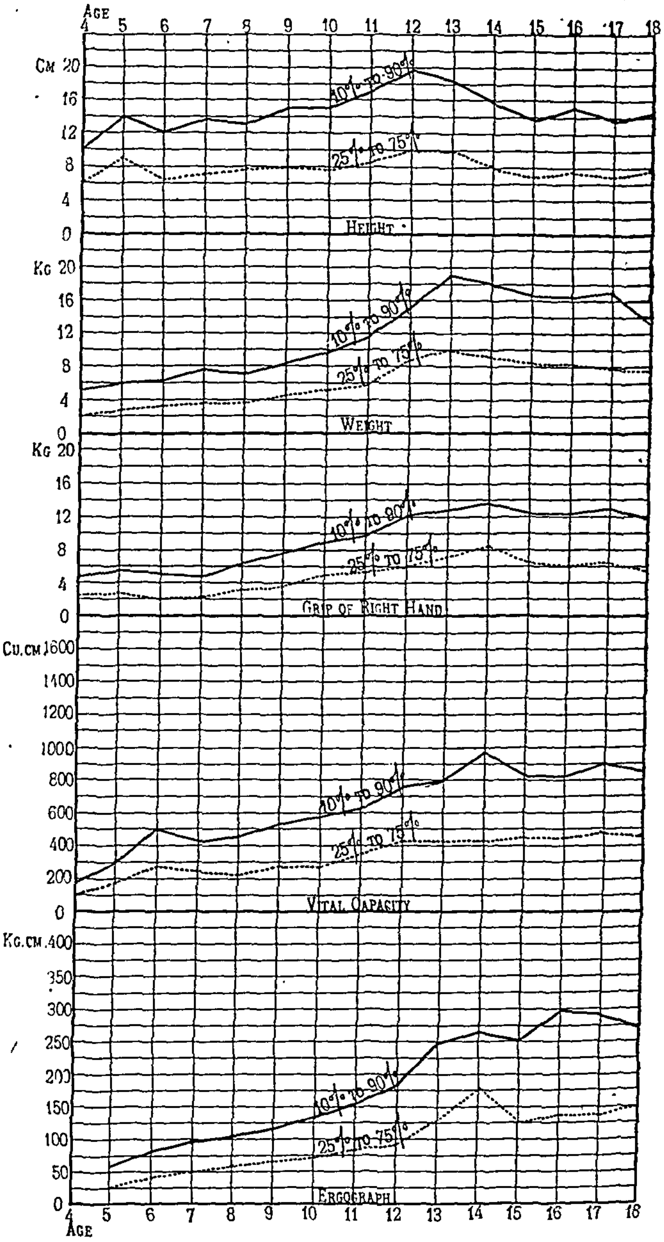

Chart 6.—Absolute range of measurements between percentile groups—Girls. Based on data in Table VII, columns 3 and 4.

3. Activities, physical and mental.
4. Commensurable physical conditions for which norms have been determined for comparison. *(a)* Weight. *(b)* Height. *(c)* Height sitting. *(d)* Strength of grip; right and left. *(e)* Vital capacity. *(f)* Endurance.
5. Relative capacity of other organs to demands made upon them, especially the heart and brain, and for which norms as to capacity do not exist, and possibly cannot be determined, but which must be estimated by means more or less indirect.

6. Conditions and symptoms resulting from the lack of balance.

For purposes of illustration a few cases are presented. With each case brief descriptive notes are given, together with a series of measurements of heights and weights. The age of the patient at the time of each measurement is given, together with the age at which the measurement found will be the normal average, according to Tables 2 and 3. This gives a basis for estimating the condition of developmental balance. In these cases no attempt at completeness of exposition is made, as it would only obscure the illustration of the condition of unbalanced physical development and its resulting morbid manifestations.

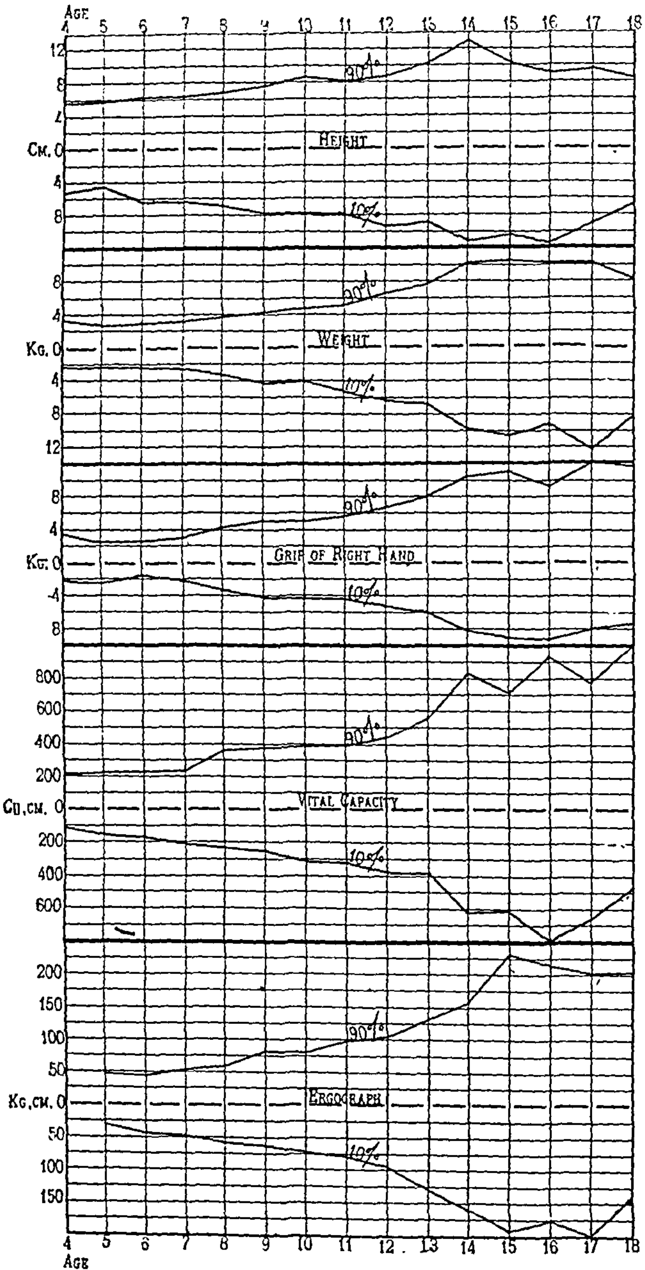

Chart 7.—Absolute range of measurements between percentile groups, distributed with reference to the average measurements—Boys. Based on data in Table VI, columns 1 and 2.

* Above highest normal average of tables.

Epileptic; excessive and rapid weight increase; unusual exertion always followed by convulsions.

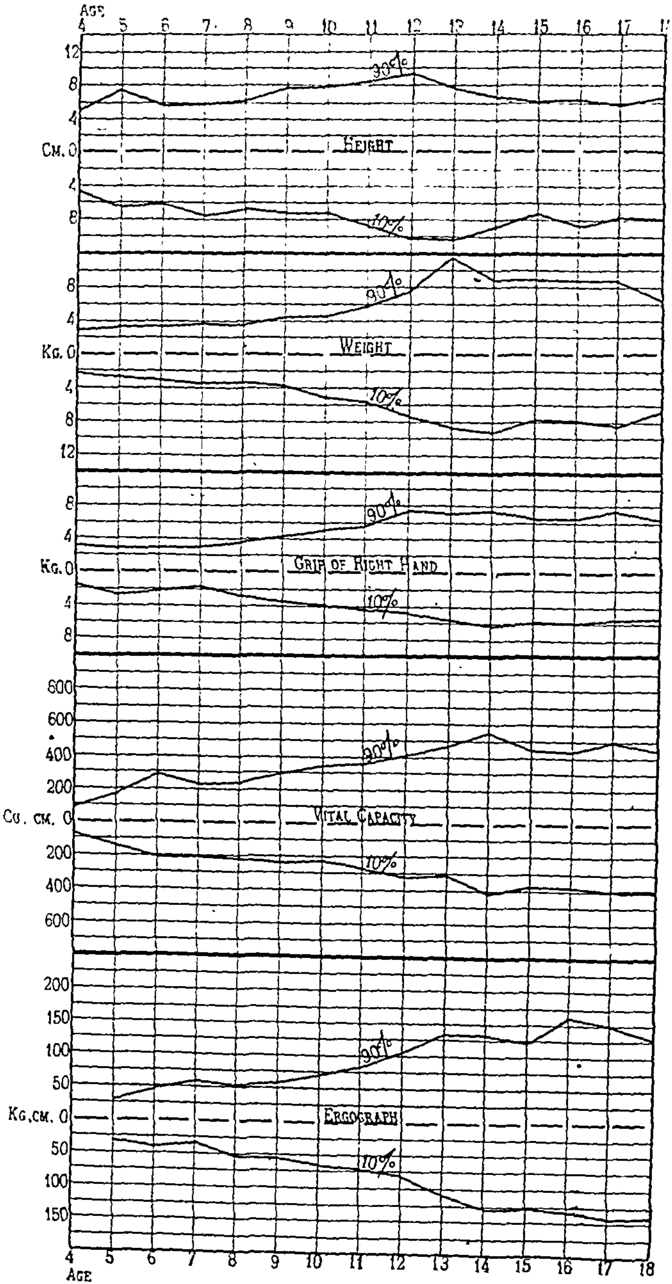

Chart 8.—Absolute range of measurements between percentile groups, distributed with reference to the average measurements—Girls. Based on data in Table VII, columns 1 and 2.

Case 2.—Marjorie P.—Birthday, March 5, 1891.

Date.		Age. Yrs.	Age. Mos.	Normal Age for Ht. Yrs.	Normal Age for Ht. Mos.	Normal Age for Wt. Yrs.	Normal Age for Wt. Mos.	Net. Ht. mm.	Wt. lbs.
00-12 22	....	9	10	12	9	12	2	1464	77.7
'01-2-2	....	9	11	13	1	12	6	1481	80.0

5-18	....	10	2	13	5	12	9	1506	83.3

Bad temper; cries easily; does not like to play; marked mental hebetude; stooped shoulders; perfect picture of fatigue. In four months' time height has increased 8 months, and weight has increased 7 months, and both were, when first seen, much above normal—height 35 months, and weight 28 months. A typical case of excessive growth and profound fatigue. Is improving.

CASE 3.—GRACE L.—BIRTHDAY, DEC. 9, 1888.

Date.	Age. Yrs.	Age. Mos.	Normal Age for Ht. Yrs.	Normal Age for Ht. Mos.	Normal Age for Wt. Yrs.	Normal Age for Wt. Mos.	Net. Ht. mm.	Wt. lbs.

4-25	12	5	18	8	15	8	1597	109.8

Fatigue; anorexia; stoop shoulders. From above table the following is formulated: In two months weight increased 1 month; fatigue and stoop. In 23 months height increased 39 months, weight increased 26 months; fatigue and stoop. In 9 months height increased 13 months, weight increased 5 months; fatigue and stoop. In 4 months height increased 3 months, weight increased 11 months; improvement: started to school. In 3 months height increased 27 months, weight increased 2 months; again fatigued.

CASE 4.—EDWIN L.—BIRTHDAY, APRIL 4, 1887.

Date.	Age. Yrs.	Age. Mos.	Normal Age for Ht. Yrs.	Normal Age for Ht. Mos.	Normal Age for Wt. Yrs.	Normal Age for Wt. Mos.	Net. Ht. mm.	Wt. lbs.

* Above highest normal.

Subnormal height and weight, with excessive school work; *fatigue. Taken from school, '97-12-8; returned* to school, '98-9-5, in excellent condition; '01-2-5, shows work of first year in high school is beginning to drag on her.

CASE 8.—DAVID I.—BIRTHDAY, MAY 4, 1887.

Date.	Age. Yrs.	Age. Mos.	Normal Age for Ht. Yrs.	Normal Age for Ht. Mos.	Normal Age for Wt. Yrs.	Normal Age for Wt. Mos.	Net. Ht. mm.	Wt. lbs.
'00-10-20	13	6	15	1	14	6	1587	99.3
12-22	13	8	15	4	15	..	1602	105.0
'01-5-4	14	..	15	11	15	4	1635	110.4

A magnificent fellow, height and weight above normal, but balanced, and not increasing beyond the capacity of his nutritive organs and heart. No functional disturbance of any kind. Prescribed golf, baseball, and tennis. Is the stuff of which good athletes are made.

The following conclusions are offered:

1. There is an exaltation of life processes at the pubertal period which finds its expression not only in an increased rate of growth, but also in the development of physical power. This exaltation is preceded by a period of relative quiescence. In the sexes this exaltation differs in that it commences earlier and has a shorter duration in girls than in boys; moreover, it is more marked in girls than in boys in weight and stature, but less in measurements involving physical power.

2. Puberty is also a *period of great individualization*, as indicated by the great normal range of physical measurements at this period.

3. The range of physical measurements at all ages in childhood, including puberty, is distributed uniformly above and below the line of average measurement.

4. At puberty mortality is low and morbidity is high.

5. Neuroses, psychoses, neurasthenias, cardiopathics, deformities and anemias are the principal morbid manifestations of the physical, intellectual and emotional turmoil which characterizes puberty.

6. The great range at puberty of the measurements of the physical features of the child expresses the condition which permits the existence in individual children of unusual lack of balance in physical measurements, or maladjustment of physical features.

7. Unbalanced physical development is an important factor in the production of morbid manifestations. It is operative throughout the developmental period of life. It occurs with greatest frequency at puberty, and it there finds its most marked expressions. It is found associated, in a causal relation, with most of the morbid manifestations of puberty, particularly disturbed heart action, dilatation of the heart, fatigue, anemia, and some deformities, such as round shoulders and scoliosis, as well as many of the neuroses of the period.

Clinical Reports.

REDUCTION OF DISLOCATION OF THE SHOULDER BY CONTINUOUS TRACTION.

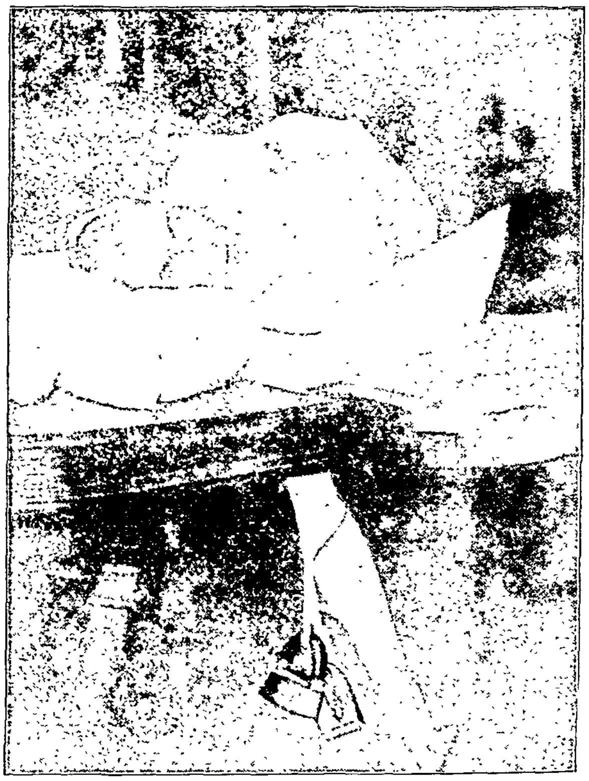
JOHN GLENDON SHELDON, M.D.
Surgeon-in-Chief to the Montrose Hospital; Consulting Surgeon to the Telluride Hospital.
TELLURIDE, COLO.

Dr. L. A. Stimson[1] described a method of reducing recent shoulder and hip dislocations, which he used with very gratifying results. His method appealed to me as being scientific and practical; hence, I have made use of the principle in all recent cases of dislocation of those parts coming under my care since his article was published. The results were so satisfactory that I feel justified in noting them.

The principle on which reduction of dislocations of the shoulder by continuous traction depends, is that the muscles are relaxed and rendered passive, thus offering no resistance to the movements of the humerus. There remains, then, only the ligaments and the atmospheric pressure to prevent reduction. The ligaments of the shoulder are so arranged that they offer no resistance to it and the looseness of the capsule is so great that the arm will fall about an inch from the scapula when the muscles are dissected from the capsular ligament and an opening is made in it to remove the atmospheric pressure. From the foregoing, it is evident that when the resistance offered by the muscles and by the atmospheric pressure is overcome, which is done by the slow, continuous traction on the arm, the capsular ligament allows the articular surfaces of the scapula and head of the humerus to be separated to such an extent that they become placed opposite each other, and when the traction is removed they return to their proper places—reduction having been accomplished.

Technique of Reducing the Dislocation.—The method of reducing the dislocation, as recommended by Stimson, is as follows: Place the dislocated arm through a 6-inch hole, made 18 inches from one end, in a canvas stretcher, the patient lying on the stretcher in a lateral position; a ten-pound weight is then attached to his wrist. In all cases tried, reduction was completed in six minutes.

Hofmeister applied the same principle and obtained equally good results, by using a complicated set of pulleys. In my first cases, the following method was used: The patient was placed on an ordinary dining table, in the lateral position; the dislocated arm allowed to hang through an opening made by removing one of the leaves; the patient supported by pillows and blankets, and the necessary number of flatirons attached to the wrist or elbow. In six cases treated by this method, reduction was accomplished at the end of six minutes in each of them. In some of the cases, at least, the reduction appeared to be effected in a shorter period; but this was not proven, as each time the weight was attached for the six minutes.



It occurred to me that carefully applied muscular force could be substituted for the weights, and, therefore, in treating the next dislocation of the shoulder, I pulled gently and steadily on the arm, held at right angles to the body, the patient relaxing his muscles. This he did, willingly, for he found that the traction was painless. After I had pulled gently and continuously for about two minutes, I felt the arm twist slightly, and, on relaxing my hold, found the dislocation reduced. I have tried this method in 7 cases and have succeeded in reducing the dislocations in all of them. In no case was I obliged to apply the traction longer than four minutes, and in most instances, a shorter period was sufficient.

The advisability of employing this method of reducing shoulder dislocation may be considered from two standpoints.

---

[1] An Easy Method of Reducing Dislocations of the Shoulder and Hip, N. Y. Med. Rec., March 3, 1900.

It offers the following advantages: 1, It has not failed to reduce a dislocation in any case. Stimson tried it on 10 cases, and I have reduced 13 cases; 6 by the use of weights and 7 by substituting muscular force for them; 2, in no case has the patient complained of the reduction being painful; 3, there has been no evidence of injury to the soft parts in this method of treatment, and it is difficult to understand how such could occur when so little force is used; 4, anesthesia is unnecessary, and 5, I have succeeded in reducing dislocations by this method where other methods have failed.

The disadvantages are, thus far in my experience, none. Of course, it is possible that some cases of shoulder dislocations can not be reduced by the method, but I have not found them. Traction on the arm, at right angles to the body, is advised against by most writers, on account of the danger of injuring the vessels and nerves. I do not think the objection holds in cases where such mild traction is used as is advised in the method of treatment outlined in the foregoing. I can see no reason why the method should not be tried in reducing shoulder dislocations, and judging from the results I have obtained, though the cases are few in number, *it is the best method for treating recent cases.*

BABE WITH ONE LUNG.

RALPH HANSON, M.D.

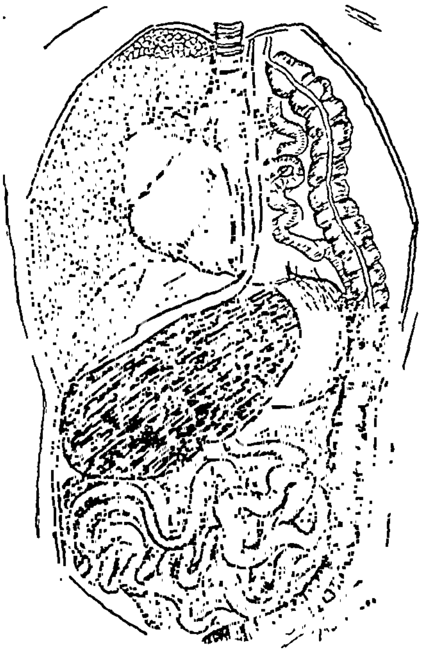
LEWISTOWN, ILL.

Mrs. W. G. M. was delivered after a normal labor of a seven-pound female child on October 27, 1900, at about the thirty-sixth week of gestation. It breathed immediately, but not satisfactorily, the respirations being shallow and at too long intervals. There was no cry; the color was pale. The pulse in the cord was strong so the child was removed from the mother, and all usual efforts made to establish normal respiration, but without success. The respirations became less frequent and more shallow and ceased entirely in about fifteen minutes. The heart continued beating for several minutes longer.

In working with the child the heart-beat was discovered to be on the right side and was easily felt, and the impulse was visible to both myself and the nurse. I thought I had a case of transposition of the viscera, and asked for permission to hold a postmortem examination, which was granted.

On opening the chest the heart was found on the right side, just to the right of the sternum and base under right nipple. The right lung was normal in shape, but rather smaller than usual. The left lung was rudimentary in the extreme and looked like a bunch of millet seed not longer than a buckshot, the bronchus being simply a cord about one-twelfth of an inch in length. The diaphragm was normal on the right side, but was only a small band of muscular fibers about one-eighth of an inch in width along the border of the ribs. There was nothing on the posterior wall to indicate where it should have been, this wall being perfectly smooth from apex to pelvis.

The liver and stomach were normal in size and position. The small intestines were as usual, except the lower portion turned to the left and ascended behind the stomach *into the left chest* cavity at the apex of which it entered the cecum. The vermiform appendix lay in the apex against the clavicle. The colon passed directly down from this point to the sigmoid flexure. The pelvic organs were normal.



History of the Clinical Thermometer.—*Janus* quotes from Daniels' history of the thermometer at the sick bed, recently published in the *Tijdschr. v. Geneesk*, that Currie, of Edinburgh, employed a thermometer in treating typhoid patients with the cold douche, as early as 1797. His example was not followed by others, and he was even held up to ridicule by his German contemporaries as an "instance of the sad condition into which English medicine has fallen." To Sanctorius of Padua, professor of medicine and author of the famous book "De Statica Medica," belongs the first clinical application of the thermometer. He invented a kind of air-thermometer, open at one end. After being held by the patient the attached tube was plunged into cold water and the height of the column of water was recorded. The great Dutch physician Boerhaave taught the importance of the temperature in disease, and used the thermometer. Van Swieten, one of his pupils, recommended Fahrenheit's thermometer for the purpose, but to another pupil, De Haen—1704 to 1776—is due the honor of having introduced the thermometer into current use at the bedside. It was not till 1835 that thermometry began to make real progress, and not till 1850 to 1870 that it came into general use, mostly due to Traube and Wunderlich's studies on temperature in disease.

Hygienic Advantages of Evening Dress.—An eminent English physician states that the evening dress suit is a distinct hygienic gain. It compels the changing of the clothes, the æration of the body. The wearer feels obliged to stand more erect, to throw out his chest and thus breathe deeper. In short, he contends that a change from the business to the dress suit every evening will add years to one's life.

THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION

61 Market Street : : Chicago, Ill.

Cable Address: "Medic, Chicago"

Subscription price: Five dollars per annum in advance

SATURDAY, SEPTEMBER 14, 1901.

THE ATTEMPTED MURDER OF THE PRESIDENT.

Our country has been called again to bow in sorrow and, at the same time, in humiliation. In sorrow, because an honest, laborious, well-meaning patriotic public servant has been murderously assaulted while doing his duty, and this without any cause whatsoever. In humiliation, because here, in this land of free speech, of free press, and of democratic government, where the poorest has as much to say who shall be ruler as the most wealthy; here, where the ruler is as a brother to the poorest citizen, where despotism is unknown and liberty in its broadest sense is the heritage and the right of all; here the anarchistic assassin plies his accursed work and excuses his deed by calling it a righteous one.

With feelings of sorrow and abhorrence, mingled with rage, the American people have again stood in the presence of their chief magistrate lying prostrate from a bullet sent by the hand of a being in the form of a man, but who, thank God, bears a name that can not be mistaken for that of an American.

Murder most wanton, murder most foul, murder absolutely unprovoked, yet deliberate, predetermined, and carried out with the tactics of a snake, was attempted. And why? Because William McKinley stood for law and order; because he was the representative of the government. There was no other reason, not even an imaginary one.

Shall we say that Leon Czolgosz is a degenerate? If by this is meant that he is worse than his fellows, yes. If by this is meant that he is so constituted by birth or development that he is physically abnormal and therefore not responsible, no. This idea of calling degenerates all those whose views of affairs become perverted by association with those who glory in pulling down everything that exists because it does exist, by reading only firebrandish literature of anarchism, and by devoting their time to concocting arguments against the fundamental principles of law and order and good government, is absurd. No, Czolgosz is an anarchist, that is all.

So let us leave him and turn to the other side. President McKinley is living to-day, thanks to the skill of the surgeons. This prospect of a fortunate result in this case of national and world-wide interest is due to the prompt surgical intervention and the application of the best technique and surgical science of to-day. But for these, the anarchist's bullet would have been successful or a practical miracle would have had to have occurred. Those who were called on to save the President deserve all the praise and honor that will be theirs for having proved themselves equal to the occasion.

Surgeons are being called on daily to do more delicate and more difficult operations than was this on the President, but in a patient so illustrious, it required courage in any one who should attempt it. A critical world watched, and the hopes of a nation were centered on this operation, and a false step, or faulty technique in the slightest degree would mean a mighty disaster. Had there been lack of prompt decision to operate, irretrievable damage would have been done, and the tragedy would have been complete.

This prompt decision to operate gave evidence of courage as well as rare surgical judgment. Perforation of the gastro-intestinal tract into the peritoneal cavity is a most serious condition in any case and those who attempt to meet it know that conditions may be revealed when the abdominal cavity is opened that might defy even the surgical skill of the day to overcome. It is for this reason that courage in this case was necessary. When the cavity was opened and the stomach and the intestines had been examined and two openings in the stomach was the sum of the pathological lesions found, the surgeons certainly breathed more freely, for modern surgery was equal to the emergency. If conditions passing surgical skill had been discovered, who can tell what imprecations would have been heaped on those who operated, when death should end the scene!

We repeat: under the circumstances, it required courage for the surgeons to do their duty, but they did it. The medical profession of America is proud of and congratulates the surgeons who worked so faithfully to save the chief magistrate of the Nation. They only did their duty, it is true, and thousands of others might have done as well, but nevertheless praise is theirs and we accord it.

THE METHODS OF THE ANTIVIVISECTIONISTS.

There has just come into our hands a pamphlet entitled "Concerning Human Vivisection, a Controversy," which calls for some notice. It contains the original letter of Mr. James M. Brown, the president of the American Humane Association, to Dr. W. W. Keen and the latter's reply published in The Journal, together with a counter reply or "Review" of the same by an anonymous writer.

It is unfortunate that the American Humane Association can not in its publications give evidence of the truth of the assertion of its president in a recent communication to The Journal that it "can have no quarrel with the medical profession." Its first pamphlet on "Human Vivisection" showed an animus to make the greatest use and widest application of certain alleged facts against the profession generally, not so much by specific statement as by the utmost utilization of illegitimate inference. In the pamphlet just received, the same spirit is manifested. If the Association had really desired to put the matter fairly before the public why did it not include Dr. Keen's last letter? If it had done this the anonymous reviewer would have had an opportunity to point out the "serious misquotations" spoken of by Mr. Brown in his recent communication (August 31), if they existed, a possibility of which we have our doubts. A writer who meets the proven charge of interpolation of whole sentences and ideas foreign to the context in an alleged quotation, as in the Schreiber case, only by admitting a "far too free translation" and who leaves an important term like *carcinoma disséminé* in the original rather than put it into intelligible English, is not one that inspires faith in his criticisms or the accuracy of his assertions.

The subject of human vivisection appears to have been brought up as a side issue to help the general antivivisection crusade, and Dr. Keen's remarks before the Senate Committee that some of the references to the experiments quoted were vague and indefinite, and in other cases that they were garbled, was the starting point of the present controversy. Dr. Keen has fairly proved his statement, as will be admitted by any one who reads his first letter, and it it difficult to conceive how any clear-headed individual can be made to believe the contrary. The attempt to make out a difference of meaning, because in his oral statement he did not use the word "references" but spoke only of experiments, is an unworthy quibble and would not be made except by a quibbler. The context shows that he could mean nothing else, and the quibble is not an answer to the fact that he fully proved their vagueness and indefiniteness as well as the garbling of the quotations.

When a reviewer attempts to excuse the addition of words and sentences to pervert the meaning of an alleged quotation on the plea of the necessity of "brevity of quotation" it is hard to believe he is not conscious of being a humbug. When the original authority is referred to, and in his "review" the anonymous author quotes the original text, the value of the plea of non-responsibility for the "far too free translation" can be properly estimated. The only way one can account for the vagaries of the reviewer in this case is on the theory that he possesses an altogether vicarious conscience that enables him to disregard the ordinary moralities of veracity and the observance of the ninth commandment.

The impression the Humane Association seeks to convey through its anonymous champion is that the medical profession commonly indulges in what it calls human vivisection and that it is generally an apologist and supporter of unjustifiable experiments on human subjects. The fact is there have been a few rare instances of the kind that were promptly condemned by the profession generally, long before the Humane Association ever paid any attention to the subject. The medical conscience is alert on this matter, for if human life and welfare is sacred to any one it is to the physician, and in this he is in bright contrast to the average antivivisectionist. There are other experiments that are questionable in their propriety though their results are not serious, but these also are few and are generally condemned. There are still other cases that are open to misconstruction and misrepresentation; every new operative or therapeutic measure is in its way an experiment, and the venturesome investigator is liable to charges of recklessness and inhumanity by such critics as those of the Humane Association. Ephraim McDowell was in danger of his life from the humanitarians of Kentucky in his day; only his brilliant success saved him, and he was even then under the condemnation of the conservatives of his own profession.

If the antivivisectionists had their way there could be little progress in medicine and surgery; the chance for President McKinley's life is due to the sacrifice of hundreds of lower animals, and the courageous application of the facts thus gained on human subjects falls fairly within what Mr. Brown and his anonymous hack writer would call human vivisection. Twenty-five or even twenty years ago, President McKinley's case would have been hopeless from the start, and if the antivivisection branch of the Humane Association had had its way it would have been so now. Twenty years from now other conditions at present hopeless will probably be within the physician's and surgeon's control, but only through experimentation on the lower animals and the cautious but fearless testing of the results thus gained on the human system.

No one can calculate the beneficial results to mankind of the recent yellow fever experiments in Cuba attended as they were by risk voluntarily assumed and even loss of life. If the justification of such deeds as these is what the Humane Association calls "suggestion of excuses for offenders," they may go on with their threatened exposure of the "crime against civilization" as rapidly as they may desire, only we would suggest to them and their writers that a disregard for truth, not only in direct statement but also in insinuation, is neither advisable nor commendable. So far there seems to have been a very general lack of consideration of this fact in their contributions to the present controversy, especially by their anonymous hack writer.

ACCIDENTAL SERUM DEMONSTRATION.

The Calmette antivenene has, as we learn from the Paris correspondent of the London *Lancet*, been put to the test as regards its efficiency by Dr. Calmette himself on his own person. While handling one of his reptiles the forceps slipped and he was severely bitten in the right hand. He immediately gave himself an injection of antivenene, and though his hand swelled considerably and there was some fever, he was able to attend to business on the afternoon of the same day, and was perfectly recovered on the following one. The serpent was one the poison of which is exceedingly rapid in its action, and the result is claimed as conclusive proof of the protective virtue of the serum. While an experiment like this is hardly to be recommended, the accident was in its way a fortunate one, and was doubtless as satisfactory to Dr. Calmette as if it had been premeditated.

DOG LIVER OIL.

The latest consumption cure—or rather one of the latest, for new ones are bobbing up almost daily—hails from one of our interior cities, and, as given out in one of the dailies of that city, it does not seem an attractive one. The gentleman who has the contract for the removal of dead animals from the streets has found that an oil prepared from the hearts and livers of dogs is a sovereign cure, and a number of cases are named where wonderful results are said to have followed its use. All other seekers for a cure are said to be wasting their time, now that the virtues of the extract from the hearts and livers of deceased canines have been discovered; thus dog liver, not cod liver, oil, is to be the oil of the future. The associations in the account are not exactly such as to make the preparation particularly appetizing, but what does that matter with an infallible cure for such a disease! It finds a utility in even a dead dog, which has heretofore been the very superlative expression of worthlessness.

THE OFFICIAL BULLETINS.

The judicious method of imparting information to the public by bulletins of the President's condition, is a feature that is to be commended. The possibilities of misconstruction of statements and the danger of premature announcements have been very evidently considered. In a case like this, medical secrecy is of course impossible; the people demand information, but it is a matter of some importance that the facts are given out in such a way that they can not be distorted by the imagination of the recipients. The surgeons in attendance on President McKinley have adopted the plan of having every official bulletin signed by the President's secretary as well as by themselves and have, in spite of pressure, apparently refrained as far as possible from any individual expression of opinion. The public can, therefore, feel assured that what it learns is reliable and that there is no confusion of individually expressed opinions or medical gossip in regard to the case. While the President is a public character he has also the rights of a citizen, and it is proper, therefore, that what is given to the public and which in the nature of the case it has a right to demand, should be sent out under official sanction and as it were from the President himself.

INFECTION OF THE URINARY BLADDER.

By reason of the frequent presence of intestinal bacteria, or the colon bacillus, in the bladder, in cases of cystitis, and of the anatomic relations of the rectum and the bladder, it has been thought that under such circumstances direct infection takes place from the rectum. It has, further, been possible experimentally to excite cystitis by inflicting injury upon the rectal epithelium. In order to verify or refute these propositions R. Faltin[1] undertook an experimental investigation, as the result of which it was found that following a lesion of the rectum at the level of the prostate, however profound or extensive, neither cystitis nor the presence of intestinal bacteria in the bladder was observed so long as the latter viscus was uninjured, providing fatal general infection or peritonitis did not occur at the same time as a result of the lesion. Such infection or peritonitis was rather frequent, especially in the sequence of more considerable lesions. Under these circumstances elimination of bacteria through the kidneys may take place and give rise to bacteriuria. In one series of experiments, cystitis developed gradually but once without simultaneous septicemia or peritonitis, and in another series transitory bacteriuria but once. On the other hand, microscopic examination of the rectum and the bladder showed that at times bacteria in large number may invade the rich lymphatic structures between the rectum and the bladder and surrounding the prostate, the seminal vesicles and the bladder beneath the peritoneum, in the sequence of quite inconsiderable lesions of the epithelium. If the bladder is injured in consequence of artificial retention, intestinal bacteria may occasionally find their way from a wound of the rectum along the anatomical paths indicated, with the development of bacteriuria or cystitis.

THE ETIOLOGY OF YELLOW FEVER.

The experiments of Reed, Carroll and Agramonte, while generally accepted as conclusive by the scientific world, are not so accepted by some of the adherents of Sanarelli. One of the most striking attacks on the mosquito theory of the conveyance of yellow fever infection has been made in a paper read before the National Academy of Medicine of Rio Janeiro by Dr. J. B. Lacerda and published in the *Brazil Medico* of August 1. The author rejects the diagnosis of the American physicians because he does not find in their reported cases the characteristic symptoms of yellow fever, the anuria, etc., and all recovered completely in a few days (ignoring the case of Dr. Lazear), and in other ways he deduces that their conclusions are unjustified and fallacious. His great argument, however, is that Sanarelli's bacillus is an established fact, and that it is presumptuous on the part of any one to question it. The clinical picture of yellow fever, he says, is throughout that of a bacillary disease like typhoid or plague, and nothing about it indicates a protozoan origin which he assumes is accepted by Reed and Carroll. Their work therefore is, he claims, unscientific and their attempt to discredit the discoveries and theory of Sanarelli, whether through partisanship or in a general spirit of opposition by unestablished and imaginary findings, is to deliberately seek to obscure the clear facts of science and hinder the onward march of truth! The later results of experimentation must be now known to Lacerda, but in Dr. Caldas, whose serum has failed, he will probably still find an ally in questioning the diagnosis. The paper is, however, altogether too *a priori* and his insinuations of national prejudice, etc., on the part of the American investigators are, to say the least, unscientific. The mosquito origin of yellow fever will be none the less generally accepted, until some stronger points are made against it.

---

[1] Centralblatt f. d. Krankheiten d. Harn- und Sexual-Organe, Band xii, Heft 8, p. 401.

THE PRESIDENT'S CASE AND THE NEWSPAPERS.

The majority of the newspapers of the country have honestly tried to supply their readers with all the facts, and only facts, about the President's case. But the possibilities for the "fake" in yellow journalism were too many to be ignored and consequently these were "extraed" with profitable results to the proprietors. While the bulletins of the attending men repeatedly announced that their patient was resting comfortably, these newspapers contained columns, double-leaded and scare-headed, about the "agony" and the "torture" which the President was bravely bearing, all pure "fake." The "agony" of the operation consisted in the little unpleasantness of the first few whiffs of the ether. Except when the wounds were dressed, the President has had no pain, and the dressing of the wounds probably caused but little suffering, if any. There would be no pain from the wounds in the stomach, and of course none from the abdominal wound, unless vomiting ensued after the anesthetic, which we understand was not the case. As is usual in such cases, a few of the newspapers have been free with advice as to what should and what should not have been done by the surgeons, this supplemented by suggestions from members of our profession in the form of interviews. As a rule, those in attendance on a case know better what are the conditions and how they are to be met than outsiders. This does not seem to be realized by some, who, we are sorry to say, belong to the medical profession. The papers are placing the credit of the successful outcome where it belongs. There is no attempt to belittle the work of the surgeons or to reflect on the good judgment of those in charge of the President's case. The advance of surgery is acknowledged by one paper in the sentence: "The surgery of to-day and not that of twenty years ago was applied to the stricken President." Another says: "The public in its gratitude for the progress made by the president within the most critical period following the operation will not forget the credit due to the surgeons who attended and to the practitioners who during the past half century have worked with such good purpose in securing the wonderful advance of surgical science." And another: "If he should finally recover, as all signs now indicate, it will be justly regarded as the most notable triumph of twentieth century surgery." In similar manner the newspapers are all speaking a good word for modern medicine.

The Shooting of the President.

(From our Correspondent.)

Buffalo, N. Y., September 12.

Within an hour of the infliction of the wounds received by President McKinley, he was operated upon at the Exposition Emergency Hospital. The surgeons present were Drs. Matthew D. Mann, Professor of Obstetrics and Gynecology, University of Buffalo; Dr. Herman Mynter, Professor of Operative Surgery, University of Buffalo; Dr. John Parmenter, Professor of Anatomy and Clinical Surgery, University of Buffalo; Dr. E. Wallace Lee, of St. Louis, Mo., who happened to be on the Exposition grounds; Dr. Eugene Wasdin of the Marine-Hospital Service, and Dr. Presley M. Rixey, physician to the President.

The operation was performed by Dr. Mann; first assistant, Dr. Herman Mynter; second assistant, Dr. John Parmenter; third assistant, Dr. Lee. Dr. Eugene Wasdin gave the anesthetic, which was ether. The operation lasted forty-five minutes. Dr. Rixey arrived at the latter part of the operation. There were two wounds, one about the center of the sternum, the other two and one-half inches below the free costal border on the left side and in the semilunar space. It was this latter wound which necessitated the speedy operation. A five-inch incision was made and the course of the bullet followed up. It was found to have penetrated the anterior wall of the stomach. The opening was small and was sutured with silk. After closing this a search was made of the intestines; the stomach was lifted from its position and a larger perforation was found in its posterior wall. It was over an inch in diameter, jagged and irregular. This wound was sutured with black silk also. Continuous catgut was used for the fascia. The skin was coaptated with six through-and-through silkworm stitches, and interrupted catgut was passed between the silkworm gut. The abdominal cavity was thoroughly irrigated with normal salt solution. There was very little food in the stomach at the time of the shooting; because of the dexterity of the operators and this happy incident no foreign matter entered the peritoneal cavity from the stomach. The wound was closed with catgut, without drainage, and bandages were applied. The bandages were removed at 8:30 a. m. Saturday and showed but little staining.

Before anesthesia had passed off, the President was conveyed by ambulance to the residence of Mr. John G. Milburn, president of the Pan-American Exposition, the emergency hospital being for temporary use only.

There are three nurses and three orderlies in attendance on the President. Dr. Rixey and one of the surgeons are with the President each night, and consultations of all the surgeons are held three times a day. Dr. Roswell Park was at Niagara Falls and came on a special train, and assisted during the latter part of the operation. He is surgeon in charge. Dr. Charles McBurney, New York, was called in consultation on Saturday, and is still here. He is the guest of Dr. Mann.

The surgeons are much inconvenienced by the incessant inquiries from reporters and are very guarded in their remarks.

NURSES ATTENDING THE PRESIDENT.

The male nurses in attendance on the President are from the United States Army Hospital Corps, who were detailed for this duty immediately after the shooting of the President, from the detachment of Hospital Corps men on duty with the Field Hospital Exhibit of the Army Medical Department at the Pan-American Exposition. The men selected for this responsible duty were Acting Hospital Steward Palmer A. Eliot, and Privates Ernest Vollmeyer and John Hodgins. All of these men completed the excellent courses of instruction at the School for Hospital Corps men at the Army General Hospital at Washington Barracks, D. C.; besides which Steward Eliot is a graduate of the Bellevue Hospital Training School for Nurses, and Private Vollmeyer is a graduate nurse of the Presbyterian Hospital of New York City. Private Hodgins is a soldier of nine years' army service and long experienced in military hospitals. Much of the attention required in the President's case is of such nature as can not well be performed by female nurses in attendance, and the efficiency of these men is such as to have elicited much favorable comment from the staff of attending surgeons. Army medical officers are highly gratified that the hospital corps should be officially connected with the President's case and have the opportunity of so publicly demonstrating its professional efficiency and the excellence of its personnel.

The female nurses in attendance on the President are Miss Helen Mohan, a graduate of the Buffalo General Hospital Training School; Miss Conley, a graduate of the Buffalo General Hospital Training School and lately clinic nurse at the German Hospital; Miss Hunter, nurse of Mrs. McKinley, and Miss Grace McCullough, of Baltimore, has been summoned.

As the President continues to improve the excellent judgment and great wisdom in the surgeons who first saw him in treating the President as a citizen and in not being concerned with too much formality or red tape become more and more apparent. The operation from the course of symptoms is to be regarded as an aseptic one. The heat resulting from the discharge of the revolver made the bullet practically aseptic, and the perforations of the stomach wall will heal soon because the sutures passed through normal tissue, and not, as in the case of tumor or ulcer, through diseased tissue. The wonderful dexterity of the operators, Drs. Mann and Mynter, prevented any discharge of stomach contents into the peritoneal cavity; hence no symptoms of peritonitis have or are expected to occur.

It is impossible at the present time to get a more detailed technical description of what was done at the operation than that which I have already given.

One of the surgeons in attendance was asked by a press representative to compare Garfield's case and its treatment with that of President McKinley, and in reply stated that to do so would be to give the history of the progress of twenty years of surgery. Besides, he said, the two cases are entirely different. Garfield's wound was an extremely unfortunate one in every way, hard to get at and difficult to handle. The wound of President McKinley, on the other hand, is in many respects a fortunate one. No comparison is possible.

During Tuesday night two stitches were removed, on account of some perceptible irritation. The wound was cleansed and again closed. It is the belief of all the surgeons in attendance on the President that his recovery is certain. If peritonitis were to have appeared its symptoms would have been manifest long before the time of this writing, and the fact that the kidneys and bowels have been functionating normally since Tuesday showed that the surgeons have good reason to be hopeful. Until early Tuesday morning the President received stimulants only hypodermically, but at that time was given a nutritive enema. In the afternoon beef juice was given by mouth. It is not necessary to give sedatives, for the patient gets four or five hours sleep.

Medical News.

ALABAMA.

Personal.—Dr. Blackshear, of Gordon, has located at Webb. ——Dr. Thomas S. Mitchell, Eufaula, has moved to Pensacola, Fla.

Cornerstone of Colored Hospital Laid.—The cornerstone of the Woman's Mission Congress Hospital for Colored Sick at Birmingham, was laid with appropriate ceremonies, August 29.

CALIFORNIA.

Dr. Benjamin F. Church, Los Angeles, is spending September and October in New York, engaged in special lines of post-graduate work.

Dr. Orville O. Witherbee, Los Angeles, has been elected superintendent of Los Angeles County Hospital, vice Dr. Ernest A. Bryant, resigned.

Lectures at Cooper Medical College.—Dr. Malcolm Morris, London, editor of the *Practitioner*, delivered the Lane lectures on "Affections and Diseases of the Skin," at Cooper Medical College, San Francisco, last week.

Dr. Antrim E. Osborne, Eldridge, for fifteen years superintendent of the Home for the Care and Training of Feeble-Minded Children at Glen Ellen, Sonoma County, has been succeeded by Dr. William M. Lawlor, San Francisco.

Personal.—Dr. Louise M. Richter, Garvanza, who has been ill for six weeks, has gone to Santa Barbara for a month.——Dr. Peter L. Wheeler, Oakland, trustee of the Merritt Hospital, has taken a trip to the eastern cities to study the conduct of hospitals.——Dr. Richard C. A. Urquhart, Los Gatos, has gone to Bolinas Bay for his vacation.

Physicians Warned.—The secretary of the San Francisco Board of Health states that a list is being compiled to include the names of all the physicians in the city who neglect to file certificates of birth as required by law. The law requires the filing of birth certificates just as much as it requires the filing of death certificates, and there is a heavy penalty for failure to observe the law. It is intimated that legal proceedings will be begun against every physician whose name is on the list.

COLORADO.

New Hospital at Victor.—It is rumored that the Victor Miners' Union, the Teller County Commissioners and the physicians of Victor are planning to build an emergency hospital.

On the Trail of Itinerant Physicians.—Dr. Seymour D. Van Meter, Denver, secretary of the State Board of Medical Examiners, is in Colorado Springs, investigating the doctors and alleged doctors who come to Colorado Springs, Manitou and vicinity to practice without license.

"Faith Healer" Yields.—Francis Truth, the "faith healer," who is under indictment for fraud and using the mails to deceive, has retired from business permanently, according to an agreement sanctioned by the attorney general, and has publicly burned all his papers, priestly costumes and healing appliances in the presence of representatives of the United States district attorney.

FLORIDA.

Dr. J. H. Colson, Waldo, has been appointed surgeon to the State Hospital for the Insane, Chattahoochee, vice Dr. Louis De M. Blocker, resigned.

The Pensacola Quarantine Station, which has recently been taken over by the United States Marine-Hospital Service, has been appraised at $20,000.

Personal.—Dr. John C. Bishop, of Aucilla, has moved to Alachua.——Dr. Henry H. Stebbins, Tampa, has been visiting his old home in Central City, Colo.

"Mental Healers" Bonded.—Three leaders of the Mental Science Association of the World, who were arraigned at Jacksonville for using the mails for fraudulent purposes, have been released on bonds of $5000 each. They made a specialty of "absent" treatments, with excellent financial results.

GEORGIA.

New Dispensary.—The Presbyterian Hospital, Atlanta, has opened a free dispensary and clinic at 80-82 Central Avenue.

Augusta City Hospital is now reopened after extensive repairs. The present capacity of the hospital is 75 beds, exclusive of rooms for private patients.

Personal.—Dr. George Brown, Atlanta, on his return from the Tuberculosis Congress in London, was shipwrecked near Boston.——Dr. Marion O. Fulcher, Waynesboro, late acting assistant surgeon, U. S. Army, has returned from the Philippine Islands and resumed practice in Waynesboro.

Competitive Examination.—A commission of physicians, consisting of Drs. William S. Elkin, James B. Baird and Joseph B. S. Holmes, Atlanta, has been appointed to conduct a competitive examination, in Atlanta, October 7, of applicants for appointment on the medical staff of the sanatorium at Milledgeville. This examination required by the laws of the state, is necessary to render applicants eligible for election to any vacancy that may occur on the medical staff, but does not apply to persons now holding office in the sanatorium. All applications must be filed with the chairman of the commission, Dr. William S. Elkin, Atlanta, at least one day before the time set for the examination.

ILLINOIS.

The Norbury Sanatorium Company, Jacksonville, has been incorporated with a capital stock of $9000 by Dr. Frank P. Norbury and others.

Dr. Alanson W. Hawley, of the staff of the Illinois Eastern Hospital for the Insane, has resigned, and will go to Europe to take special work in diseases of the eye and ear.

Vaccination Ordered.—The East St. Louis Board of Health has issued a proclamation enforcing vaccination on all persons, and has also formulated rules for the government of the local isolation hospital.

Sherman Hospital Once More.—Peace has decided not to brood over Sherman Hospital, Elgin, just now, despite the reports noted in last week's Journal. The ladies in charge not only formally accepted the resignations of Drs. Rutledge, Taylor and Bridge, September 2, but also cited them to appear before the next meeting of the hospital board and show cause why they should not be dismissed from the staff.

Personal.—Dr. Roy H. Garm, Beardstown, expects to practice in Rock Island.——Dr. and Mrs. James W. Cormany, Mt. Carroll, have returned from an extended visit in the East.——Dr. Samuel E. Munson, Springfield, who was injured by a runaway team in Rochester, is securely convalescent.——Dr. C. C. Rayburn, Roseville, expects to open an office in Kewanee.——Dr. J. Frank Wilson, Versailles, will locate in Bluffs.——Dr. James E. Woelfle, New Grand Chain, has moved to Paducah, Ky.—Dr. and Mrs. E. W. Weis, Ottawa, are visiting Hot Springs, South Dakota.

Chicago.

Christian Hospital has been incorporated with a capital stock of $25,000 by Dr. Emma M. Moore and others.

Needed Precautions at County Hospital.—Within a year three delirious patients at the County Hospital have escaped from their attendants and leaped or fallen from windows unprotected by bars. Two of them were killed.

Chicago Mortality.—There were 483 deaths during the week ended September 7, this being 32 fewer than during the preceding week, but an excess of 39 as compared with the corresponding period of last year. The reduction in the week's mortality as compared with the week preceding is due chiefly to the lower mortality among children under 5 years of age, and is principally attributed to fewer deaths from the acute intestinal diseases, diphtheria, convulsions and infantile marasmus. The continuance of the remarkably low mortality from diphtheria which has prevailed throughout the summer months still holds good, there having been only 4 deaths recorded as due to this disease during the week. With the reopening of the public schools, however, there has in times past been a marked increase in the contagious disease mortality—especially diphtheria.

Personal.—Dr. Robert C. Wilson has returned from a two-months' vacation at Lake Harbor, Mich.——Dr. and Mrs. George W. Whitfield, who have been spending the summer in Colorado, Utah and California, expect to return to the city September 15.——Dr. and Mrs. B. Brindley Eads have returned from their trip to the Pacific Coast and Yellowstone Park.——Dr. Harry P. Woley and wife have returned from Harbor Springs, Mich.——Dr. G. Frank Lydston has returned from a trip through Colorado and New Mexico, and has moved into his new house on Sheridan Road.——Dr. Charles Gilbert Davis has returned from his summer home, Waunita, Colo.——Dr. and Mrs. E. Perry Rice have returned from a trip on the great lakes and the St. Lawrence.——Dr. and Mrs. John E. Owens have returned from a trip to the Atlantic seaboard and Baltimore.——Dr. Violet H. Palmer, formerly of the staff of the Illinois Eastern Hospital for the Insane, has opened an office at 100 State Street.——Dr. Henry Parker Newman has sold his summer home in Highland Park and moved into his new house in Edgewater.

INDIANA.

Dr. James S. Hinkle, Indianapolis, who was injured a year ago in a street-car accident, has filed suit against the Indianapolis Street Railway Company for $10,000 damages.

An Old Offender.—A "doctor" of Mier has been arrested charged with practicing medicine without a license and with having failed to make a death return. He is reported to have been previously arrested on a similar charge, and also to have served a ninety-day sentence in the Indianapolis workhouse for passing counterfeit money.

Typhoid Fever in a Convent.—The opening of the Academy for Young Ladies at Oldenburg, Franklin county, has been postponed until September 17 by order of the State Health Board. There are many cases of typhoid fever in the mother house of the convent, although but five are considered serious. Examination of the structures on the spacious grounds revealed them to be in perfect sanitary condition, but the fifteen cisterns and four wells upon the place were immediately sealed by the officials and samples of the water reserved for analysis. During the past two months sixty cases of typhoid fever have been reported from the institution, but at present writing there seems to have been no mortality.

IOWA.

Charles Francis, Davenport, has been appointed the civil engineer member of the State Board of Health.

Smallpox was discovered in Finley Hospital, Dubuque, August 21, and the patient removed to the isolation hospital.

Smallpox.—Dr. Heinrich Matthey, Davenport, member of the State Board of Health, discovered four cases of smallpox in West Liberty, August 31.

To Raise Fees.—The Council Bluffs Medical Society has decided to raise fees for night calls to five dollars. It is to be hoped that the members will be able to raise the fees.

Dr. Bernard C. Kelly, Carroll, has been annoyed of late by an unscrupulous individual who has been traveling around Carroll county taking orders for glasses. He offers a reward of $10 for information that will lead to the arrest and conviction of the swindler.

Dr. M. Nelson Voldeng, Des Moines, was elected superintendent of the new State Hospital for the Insane at Cherokee, September 5, by the State Board of Control. Dr. Voldeng was for nine years assistant superintendent of the State Hospital for the Insane at Independence.

Personal.—Dr. McCoy had his leg broken in a runaway accident in Clinton, August 20.—Dr. Anne E. Burnett, for several years assistant physician at the Iowa Hospital for the Insane, Clarinda, has resigned and will go to Scotland for a year of study.—Dr. Edward D. Piper, formerly of Chicago and Wall Lake, has located in Moorhead.—Dr. Charles P. Tillmont has moved to Centerville.

LOUISIANA.

The Orleans Parish Medical Society has appointed a committee to investigate the mosquito in its relation to disease.

Lawrence Gomila, a member of the class of 1901, Tulane University, and an interne student in the Charity Hospital, died from appendicitis, August 18.

Tulane Appointments.—Dr. John Smythe, Jr., has been appointed demonstrator of minor surgery, and Drs. L. C. Chamberlain, C. N. Chavigny and I. I. Lemann have been appointed chiefs of clinic to the chair of gynecology, medical department, Tulane University.

MAINE.

New Physicians.—The Board of Medical Registration at its recent examination held at Portland passed fifty out of the fifty-five applicants.

Dr. Philip H. S. Vaughan, Augusta, who has been assistant physician at the Maine Insane Hospital, has moved to Bangor, where he is to occupy a similar position in the newly-established insane hospital.

Personal.—Dr. C. F. Kendall has opened an office in Biddeford.——Dr. D. W. Wentworth, York, has moved to Sanford.——Dr. John Knowlton has returned from six months of study in Germany, and will practice in Bath.——Dr. M. M. Small, Deer Isle, intends to locate in Gorham.——Dr. P. M. Andrews, Gray, has begun his work as house physician of the Maine General Hospital, Portland.

MARYLAND.

The Howard County Grand Jury has found indictment charging Dr. J. W. Sim with failure to report smallpox cases.

Killing of Flies.—The Lonaconing Health Board prescribes the killing of house flies as a sanitary measure, and an anti-pigeon law will go into effect this fall.

Smallpox.—Several case of smallpox are reported in the southern part of Caroline County (Eastern Shore) near the Delaware line, traced to a negro camp meeting.

Personal.—Dr. Joseph Ennis, Burkittsville, has moved to Waynesboro, Pa.——Dr. Frank Dorsey, Green Spring Valley, Baltimore County, has gone to Butte City, Mont.

Baltimore.

Raising Standard for Nurses.—The Sisters of Mercy in charge of the City Hospital are raising the standard in their school for nurses. The course will be a three-year one, with dietetics in the third year.

Smallpox.—In Baltimore during the past three years there have been 48 cases of smallpox, and in no instance has the disease spread beyond the house in which it was discovered. Slight outbreaks in the counties have been treated almost as effectively.

Personal.—Dr. Isabella K. Godfrey is at Atlantic City.——Drs. George A. Fleming, A. Friedenwald and J. C. Hemmeter have returned from summer vacations.——Dr. Ira Remsen, president of Johns Hopkins University, has been cruising along the coast of Maine in Mr. R. Brent Keyser's steam yacht, and is now at Bar Harbor.——Dr. C. P. Strauss is at Buffalo.——Dr. Alfred Whitehead is at Montreal.——Dr. J. L. Graham is at Boston.——Drs. L. M. Allen and H. A. Naylor sailed for Bremen from this port, September 4.——Dr. Allen will take a special course of studies abroad for a year.

MICHIGAN.

Personal.—Dr. Edward B. Patterson, Manistique, has disposed of his practice to Dr Cole, Traverse City, and will go to Europe for a course of special study.

Dr. Benjamin F. Sheeder, Saline, who has lain unconscious for five months at his father's house, in Springfield, Ohio, as a result of cerebral hemorrhage, is improving so that he now can talk and move his limbs.

W. Fred. Buck, Muskegon, a diplomate of the "Independent Medical College," Chicago, plead guilty of practicing medicine without a license, August 30, and on his promise to abandon practice in Michigan, was fined $15 and costs.

MINNESOTA.

A new contagious ward for the St. Paul City and County Hospital is to be erected this winter.

The Detention Hospital, Benson, was struck by lightning, August 28, and set on fire. Fortunately, no patients were in the building at the time.

A hospital annex to the Minneapolis Home for Children and Aged Women, is to be erected at a cost of $7000. It will accommodate about thirty patients.

The anti-vaccination movement in Minneapolis appears sluggish. At a meeting called, August 28, for the purpose of organizing an anti-vaccine society only two persons appeared, and the matter was postponed indefinitely.

Personal.—Dr. Thomas N. McLean, Fergus Falls, is taking a two weeks' vacation, and Dr. Thomas F. McLean will care for his practice.——Major H. F. Hoyt, formerly of St. Paul, who has been serving in the Philippine Islands, is visiting in Minneapolis on leave of absence.——Dr. H. F. Sterzing, Austin, Texas, has located in Mankato.

MISSOURI.

Dr. J. W. Williams, Bloomington, was fined $50 in Macon, August 29, for practicing medicine without a license. He took an appeal to the Circuit court.

New Dispensary.—Drs. John W. Perkins, B. Clark Hyde and others have established a free dispensary in connection with the North End Day Nursery, Kansas City.

Personal.—Dr. Frank Bleakney has opened an office in South St. Joseph.——Dr. F. H. Randall, house surgeon of the Wabash Hospital, Moberly, has resigned and will study in Vienna for a year.

New Hospitals.—Permits were granted to two persons to conduct private hospitals in Kansas City, on the condition that they care for children only and take no maternity cases.——Jefferson City is to have a new hospital to cost $15,000.

NEBRASKA.

Refrigerator for Creighton.—Creighton Medical College, Omaha, has awarded a contract for a refrigerating plant for preserving its cadavers.

Personal.—Dr. and Mrs. Chester A. Brink have returned to Ord after a visit in Chicago. Dr. J. J. McGirr, Beatrice, has returned from a post-graduate course in Vienna.

Lt.-Col. Charles K. Winne, U. S. Army, has been ordered to Omaha to assume charge of the chief surgeon's office of the Department of the Missouri, relieving Lt.-Col. James P. Kimball.

Smallpox among Sioux Indians has caused the postponement of the council of Sioux Presbyterians and Congregationalists, which was to have convened this month at Santee agency.

NEW YORK.

Quarantine Raised.—The smallpox epidemic in Whitehall, which began in June, is now over, and quarantine has been raised.

Age Disqualifications.—The partial examinations for medical students provided for by the last legislature can not be taken by any person under 21 years old. Many students are thereby debarred from taking the examination, and the relief sought for by the law is nullified.

Dr. C. W. Hoyt, Corning, mysteriously disappeared from a C. & B. steamship while en route from Cleveland, Ohio, to Buffalo. His body was recovered from Lake Erie at Geneva, Ohio. As no money was found on the person of the deceased the first theory that the doctor was robbed and afterward thrown overboard is confirmed.

New York State Population.—According to the bulletin issued by the U. S. Census Bureau, dated August 29, the total population of New York state is 7,268,894, the percentage being 50.3 females to 49.7 males. Of these 26.1 per cent. are foreign born and 1.5 per cent. are colored. The latter class is divisible into 99,233 negroes, 7170 Chinese, 354 Japanese, and 5257 Indians.

Buffalo.

Dr. H. R. Hopkins was seriously injured by a collision with a trolley car.

Dr. George H. Calkins has been appointed assistant surgeon of volunteers, with the rank of captain.

Dr. Irving Phillips Lyon has been awarded the Hartwig prize of $50 for his essay on cancer distribution in Buffalo for the past 20 years, with especial reference to the parasitic theory.

Dr. Preston H. Bailhache, surgeon U. S. A., has been detached as delegate to represent the service at the meeting of the American Public Health Association to be held in Buffalo, September 16-20.

Death Certificate Refused.—The coroner of Erie County has refused to issue a burial permit in a case in which the death certificate was signed by Dr. Ferdinand Simon, because the latter is not registered with the health department.

Dr. Kinyi Ugai, a graduate of Bellevue Hospital Medical College and of the Royal University of Japan, Tokyo, has registered and received a certificate entitling him to practice in the state.

Legacy to St. Luke's Hospital.—The will of the late Louis T. Hoyt provides, after the payment of certain legacies, that one thirty-second part of the residue be given to St. Luke's Hospital for the Treatment of Consumptives.

Bequests to Hospitals.—The seventeen institutions which expected to receive $25,000 each under the provisions of the will of the late Andrew J. Garvey, will now, on account of shrinkage in values and litigation, receive less than $9000 each.

Health of Buffalo.—According to bulletins from the Department of Vital Statistics, Buffalo during the last decade has been the healthiest of the large cities of the country. Buffalo is fortunate in her natural healthy geographical position and in a department of health which has as its director Dr. Ernest Wende.

The Park Avenue tunnel nuisance, which may grow into an issue at the coming autumnal elections, was not taken up at the meeting of the Health Board, as it had sent a mandatory letter, and as the New York Central road had promptly complied with what one newspaper claims to be engineering impossibilities. Smoke is to take the brunt of the battle.

More Accommodations for Smallpox Patients.—At a recent Health Board meeting two more pavilions were voted to be erected on North Brother Island. These are to be wooden structures about 100 by 50 feet and one story high. Each will accommodate thirty patients, the total cost to be $17,000. Strictly speaking, the epidemic has been thus far mild and a comprehensive quarantine has much improved the mortality statistics.

OHIO.

The next regular meeting of the Ohio State Board of Medical Registration and Examination will be held in the new office of the Board in the new State House Annex.

The entrance examination to medical colleges will be held September 27 and 28 in Cincinnati, Cleveland, Toledo and Columbus, under the direction of the examiners residing in these cities.

Personal.—Dr. Myron S. Clark, Youngstown, has been elected supreme medical examiner of the Foresters of America.

——Dr. Henry Baldwin, Jr., Springfield, has resigned from the staff of the Clark County Infirmary.

Cincinnati.

Dr. Clarence J. Beckley, interne to Christ's Hospital, is convalescing from a severe attack of typhoid fever at the home of his parents at Price Hill.

Madam Kelch, a cancer doctor, was found guilty of practicing medicine illegally at Wilmington, Clinton County, on August 30 and was fined $50 and costs.

Cincinnati Teachers' Institute.—At the third day's session, September 5, Dr. W. S. Christopher, Chicago, gave an address, "The Child Study Department in the Chicago Public Schools," and Dr. Carl Ziegler addressed the high-school section on "Physical Training for High School Pupils."

PENNSYLVANIA.

Organize Against Deadheads.—The physicians of Hazleton and vicinity have organized an association having for its object the exchange of deadhead lists among its members.

General Vaccination Recommended.—The Mahanoy City Board of Health has urged the advisability of general vaccination in view of the likelihood of an outbreak of smallpox.

Personal.—Dr. Newton S. Rice, Durham, is in charge of the practice of Dr. H. W. Johnson, Riegelsville, during the absence of the latter at the seashore.——Dr. George B. Goheene has opened an office in Glasgow.——Dr. James Love has located in *Dayton.*

Bequest to German Hospital.—By the will of the late John D. Lankenau, Philadelphia, president of the board of trustees of the German Hospital, $750,000 is bequeathed to that institution and a similar amount to the Mary J. Drexel Home for Aged Patients of the German Hospital.

WISCONSIN.

William Caswell, Hillsboro, who was found *guilty several* weeks ago of violating the state law by practicing medicine without a license, was arrested and brought to Viroqua, August 24, but escaped, and, it is believed, has left the state.

Lumber Camp Inspection.—Dr. Henry J. Connor, West Superior, has been appointed inspector of lumber camps for the State Board of Health. He will attend to the cleansing and fumigation of the camps and will also take charge of any smallpox cases in Douglas County.

Dr. H. Booth Kendall, Menasha, on August 28, was convicted of failing to report a smallpox case to the health authorities, and was fined $75 and costs. He states that he will appeal the case. Dr. Rodermund, the anti-contagion agitator, took the stand in the defendant's behalf.

Personal.—Drs. Ernest Copeland, Henry V. Ogden and Henry B. Hitz, Milwaukee, are taking a hunting and fishing trip in Northern Wisconsin.——Dr. J. E. Metcalf, Platteville, has succeeded to the practice of Dr. Thomas E. McDermott, Fennimore.——Dr. Frank Foley, Montello, intends to locate in Neshkoro.

Sanatorium for Consumptives.—A Milwaukee syndicate has been formed to build a sanatorium for consumptives in the pine woods north of Rhinelander. The project includes the purchase of 12,000 acres of land, and the projectors expect to make an initial expenditure of $100,000. Dr. Ferdinand W. Schultz has gone to look over the ground and report on its hygienic fitness.

GENERAL.

Examinations for Army Medical Department.—The examination of applicants for appointment as assistant surgeon in the army has been resumed in Washington and San Francisco; the Army Medical Boards convened in those cities will remain in session so long as there are candidates to be examined. Seventy-six vacancies in the Medical Department still *remain to be filled*, and as it is desired by the military authorities that the Department be filled up to its full legal limit as early as practicable, all eligible applicants will be afforded opportunity for examination; those found qualified will be commissioned at an early date. For further information see elsewhere in this issue or apply to the Surgeon-General, U. S. Army, Washington, D. C.

CANADA.

Anthrax in the West.—Dr. Hargrove, veterinary for the Department of Agriculture at Medicine Hat, N. W. T., states that anthrax has broken out among sheep at Little Current, and that they are dying at the rate of fifty-six per day. Fourteen thousand doses of anthrax vaccine have been wired for from a Detroit firm.

Anthrax in the East.—The outbreak of anthrax in the eastern townships around Ottawa has taken on a serious and peculiar turn. A large number of cattle were inoculated with antitoxin lymph, and a few days later they began to die off in large numbers. Postmortem examinations have shown large numbers of anthrax germs present.

Smallpox Outbreak.—Smallpox is said to be spreading rapidly in the counties of Ottawa and Labelle, province of Quebec; the disease is of the mildest character, and although there are thirty-five cases to date, no deaths have been recorded. The territory is extensive and sparsely settled, and danger is apprehended, as the shantymen who will shortly be going up the Ottawa river will be traversing the infected district.

Deaths from Consumption in Ontario.—The fight against consumption in Ontario is at last beginning to tell in the vital statistics, so says the provincial Medical Health Officer. During July of this year municipalities containing 91 per cent. of the population of the province registered only 182 deaths from consumption, as compared with 284 recorded in July, 1900, by municipalities containing 97 per cent. of the population. A small but noteworthy decline has thus resulted from the improved methods of isolation and the anti-spitting regulations.

Military Doctors Qualify.—The following-named medical officers, having successfully passed the qualifying examinations, have received certificates of proficiency: Surgeon-Major J. Ross, 77th; Surgeon-Captain R. H. Arthurs, 97th; Surgeon-Major J. M. Piper, 7th; Captain A. T. Hobbs, A.M.S.; Lieut. C. N. Lawrie, A.M.S.; Lieut. D. B. Bentley, A.M.S.; Surgeon-Lieut. Balfour, 1st Hussars; Lieut. Tremayne, A.M.S.; Surgeon-Major D. P. Lynch, 42d: Surgeon-Lieut. J. Macoun, 40th; Lieut. A. R. B. Williamson, A.M.S.; Acting Surgeon-Lieut. P. Maloney, 59th; Surgeon-Lieut. A. V. Roy, 6th C. A.; Surgeon-Lieut. Cote, 61st; Surgeon-Major L. M. Genest, 92d; Surgeon-Lieut. E. Savard, 11th; Surgeon-Major T. L. Brown, 54th; Surgeon-Lieut. H. B. Yates, 3d; Surgeon-Lieut. D. D. McTaggart, 1st.

FOREIGN.

Death of Professor Fick.—The Würzburg physiologist, Adolph Fick, died August 22, in his 73d year. His contributions to scientific literature have been numerous and valuable.

Deaths Abroad.—Dr. Hameau, vice-president of the Medical Association of France; Dr. Hermann von Widerhofer, professor of pediatrics at the University of Vienna; Dr. Steinbrugge, professor of otology at Giessen.

Steffan Is Relieved of His Title.—The title of Sanitätsrath—usually coveted by German physicians—was repudiated by Dr. Steffan, as he had no wish to pay the $75 fees attached to the title. After a year or so of red tape the title has finally been withdrawn. The authorities do not state, however, whether the fees are to be repaid or not.

Prohibition of Prescribing by Mail in Germany.—The German authorities are on the point, it is said, of prohibiting "distance treatment," that is, treatment exclusively by correspondence. The kingdom of Saxony was the first to move in the matter, and the Imperial Council of Health has indorsed the proposition, although distance treatment in thinly settled districts can not always be avoided by regular physicians. The measure is to apply exclusively to "mail order" prescribing.

The German Hospital Year for Medical Graduates.—The Prussian "Medicinalministerium" has announced the particulars of the "practical year" in some hospital henceforth to be exacted of all medical graduates before they are inscribed as fully entitled to the degree of "approbirte" physician. The list of hospitals includes only those with fifty beds at least, and the "Praktikants" are assigned one to each twenty-five beds. The list includes all the public and general hospitals, except the plague hospitals and the convalescent homes. All the institutes for special research in anatomy, physiology, pathology, pharmacology, hygiene and legal medicine are included, although not estimated as equivalent to the general hospitals. Only a certain proportion of the time spent in them will be applied on the "practical years." Such institutes, to be eligible, must possess an established scientific reputation and dispose of sufficient material, with resources sufficient to occupy the "Praktikants." The "Landrath," with the assistance of the district physician, will compile the list of eligible establishments for each region.

Married.

John F. Doudna, M.D., Lake City, Mich., to Miss Jessie Ross, of Saginaw, August 21.

S. Charles Mish, M.D., to Miss Wanda Shirek, both of San Francisco, Cal., August 25.

Samuel Mowbray Hammond, M.D., New Haven, to Miss Katherin Dayton, of Torrington, Conn., September 5.

Thomas W. Keown, M.D., resident physician at St. Agnes Hospital, Baltimore, Md., to Miss Edith Livingston, at St. Albans.

John H. Gibbon, M.D., Philadelphia, to Miss Marjorie Young, daughter of Major General S. B. M. Young, U. S. Army, at San Francisco, Cal., September 2.

Deaths and Obituaries.

George William Wells, M.D., Bellevue Hospital Medical College, N. Y., 1868, of Richmond Hill, Queen's County, N. Y., died September 2, aged 57. He was a member of the Kings County Medical Society (N. Y.) and also of the Association of Medical Directors of Life Insurance Companies. He was the editor of the *Medical Examiner and Practitioner*, and was also medical director of the Manhattan Life Insurance Co.

Gates B. Bullard, M.D., Dartmouth Medical College, Hanover, N. H., 1855, one of the best known physicians of Northern New England, died at his home in St. Johnsbury, Vt., September 4, aged 72. He served as surgeon of the Fifteenth Vermont Infantry in the Civil war; later on was made surgeon-general of Vermont, served in both houses of the legislature and was a commissioner for the insane.

William M. James, M.D., College of Physicians and Surgeons, New York, 1862, died at his home in Whitesboro, Utica, August 26, from heart disease and dropsy, after an illness of seven months, aged 62. He served as examining surgeon of recruits and as acting assistant surgeon during the Civil war, and thereafter practiced in Whitesboro and Utica.

Adolph Aronstein, M.D., University of Munich, Germany, 1860, a prominent physician of San Francisco and consulting physician to Mount Zion Hospital, died at his home in that city, August 28, after a lingering illness, aged 66.

William Barnsmore Pape, M.D., Medical College of Alabama, Mobile, 1882, died in that city, August 30, aged 51. He began a career as pianist at the age of 13, but afterwards gave his time to the practice of medicine.

Abner Franklin Bliss, M.D., Castleton (Vt.) Medical College, 1851, who had practiced for thirty-five years past in Wardsboro, Vt., died at his home in that place from pneumonia, August 13, aged 72.

Alexander Bulla, M.D., University of Wooster, Cleveland, Ohio, 1881, who had practiced medicine in Davidson County, N. C., for forty-five years, died at his home in Jackson Hill, August 20, aged 75.

R. T. McMorrine, M.D., McGill University, 1893, died suddenly at his home in Richmond, Que., September 4, aged 34. He was at one time house surgeon at Bellevue Hospital, New York City.

Clyde W. Crumrine, M.D., Western Pennsylvania Medical College, Pittsburg, 1895, of Charleroi, Pa., died at the Allegheny General Hospital, August 29, from nervous prostration, aged 32.

Lawrence Miller, M.D., McGill University, Montreal, for many years a citizen of Bellevue and Dubuque, Iowa, died after a lingering illness, August 27, at his home in Bellevue, aged 73.

John D. Kielty, M.D., College of Physicians and Surgeons, Boston, Mass., 1883, of Fitchburg, Mass., died at his summer home, East Princeton, August 27, from asthma, aged 43.

William Platt McLaury, M.D., College of Physicians and Surgeons, N. Y., 1875, long a resident of Catskill, N. Y., but more recently of New York City, died August 30.

John S. Combs, M.D., Medical College of Ohio, Cincinnati, 1850, of Owensville, Ohio, died at his home in that place, August 21, after a protracted illness, aged 80.

Daniel T. Taylor. M.D., New Orleans (La.) School of Medicine, 1859, for sixteen years a resident of Hot Springs, Ark., died at his home in that city, August 29.

John F. Baughman, M.D., Starling Medical College, Columbus, O., 1851, died, after a prolonged illness, at his home in North English, Iowa, August 29.

William S. Little, M.D., a resident of Cynthiana for fifty-one years, died from heart disease, August 21. He had been an invalid for about five years.

Robert L. Luckett, M.D., Tulane University, New Orleans, La., 1891, of Alexandria, La., died suddenly at his home in that place, August 29, aged 36.

Richard D. King. M.D., University of Nashville, Tenn., died at his home in Bells, Texas, August 19, after an operation for appendicitis, aged 37.

Frank H. Ravenscroft, M.D., Kentucky School of Medicine, 1893, died at his home in Friendsville, Md., August 19, from typhoid fever, aged 31.

Junius D. O'Brien, M.D., New York University, 1858, of Christian County, Ky., died suddenly at his home in Hopkinsville, August 23, aged 70.

Societies.

COMING MEETINGS.

American Public Health Association, Buffalo, Sept. 16-20, 1901.

American Association of Obstetricians and Gynecologists, Cleveland, Ohio, Sept. 17-19, 1901.

Medical Society of the Missouri Valley, St. Joseph, Mo., Sept. 19, 1901.

Nevada State Medical Society, Reno, Sept. 21, 1901.

Medical Society of the State of Pennsylvania, Philadelphia, Sept. 24-26, 1901.

American Electro-Therapeutic Association, Buffalo, Sept. 24-26, 1901.

Oregon State Medical Society, Portland, Sept. 25-27, 1901.

Utah State Medical Society, Provo City, Oct. 1-2, 1901.

Idaho State Medical Society, Pocatello, Oct. 3-4, 1901.

Tri-State Medical Society of Alabama, Georgia and Tennessee, Nashville, Tenn., Oct. 8-10, 1901.

Wyoming State Medical Society, Evanston, Oct. 8-9, 1901.

Vermont State Medical Society, Montpelier, Oct. 10-11, 1901.

New York State Medical Association, New York City, Oct. 21-24, 1901.

Vermont State Medical Society.—The place of the next annual meeting of this Society has been changed from Bellows Falls to Montpelier. It will occur October 10 and 11.

Omega Upsilon Phi Fraternity (Medical).—The fifth annual convention of this body was held August 29 and 30 at Buffalo, N. Y. Dr. Edward M. Thompson, New York City, was elected president, Dr. Dean O. Thompson, Hornellsville, N. Y., secretary, and Dr. George H. Minard, Lockport, N. Y., treasurer. The next convention will be held in New York City in September, 1902.

Reading (Pa.) Medical Society.—The annual meeting of this Society was held August 26. The following officers were elected: Dr. Irvin Hartman, president; Dr. Seymour T. Schmehl, vice-president; Dr. Louis L. Thompson, secretary; Dr. Oan J. Thompson, treasurer; Dr. W. Murray Weidman, librarian; Dr. M. Le Roy Wenger, curator, and Drs. M. Le Roy Wenger and Fremont W. Frankhauser, censors.

New Hampshire Surgical Club.—The sixth annual meeting of this organization was held at Ben Mere Inn, Lake Sunapee, N. H., August 29. The attendance was good and the program carried out in full. The following officers were elected: Dr. John M. Gile, Hanover, president; Dr. Arthur C. Heffenger, Portsmouth, vice-president, and Dr. Nelson W. McMurphy, Concord, secretary-treasurer.

Tri-State Medical Society of Alabama, Georgia and Tennessee.—The next annual meeting of the Tri-State Medical Society of Alabama, Georgia, and Tennessee will be held at Nashville, Tenn., October 8, 9 and 10. An interesting feature of the meeting will be a series of papers on sociological questions. The following papers have been promised: "Syphilis in the Male as a Social Question—Its Prevention," Dr. Julius A. Childs and W. Leon Champion, Atlanta; "Gonorrhea in the Male as a Social Question—Its Prevention," Dr. W. Frank Glenn, Nashville; "Gonorrhea in the Female—Its Results," Dr. Walter J. Bogart, Chattanooga; "Syphilis in Relation to Diseases of the Eyes," Dr. Alexander W. Stirling, Atlanta; "Tuberculosis—Its Prevalence and Prevention," Dr. J. Dawkins Cromer, Atlanta; "Suppression of Consumption," Dr. Richard C. Bankston, Birmingham; "Marriage and Heredity in Relation to Insanity," Dr. T. O. Powell, Milledgeville, Ga.; "The Development and Control of the Sexual Instinct," Dr. John W. Macquillian, Chattanooga; "Legislation and Its Limitations in the Prevention of Crime and Disease from a Legal Standpoint," "Heredity and Acquired Characteristics as Social Questions," Dr. Rufus R. Kime, Atlanta, and Report of the Sociological Committee through Dr. Rufus R. Kime, its chairman.

CANADIAN MEDICAL ASSOCIATION.

The Thirty-fourth Annual Meeting, held at Winnipeg, Manitoba, 28-30, 1901.

There were in attendance over 175 members from all parts of the Dominion, the second largest gathering in the history of the Association. There were several visiting physicians from the United States.

Dr. H. H. Chown, of Winnipeg, the president, occupied the chair.

The Question of Medical Defense.

Dr. Russell Thomas, of Lennoxville, Que., had been delegated by the St. Francis District Association to present this subject. He made a strong plea for the formation of a medical defense union and thought that all were agreed of the necessity for such. He supported his contentions by citing two or three cases already well known to medical practitioners in Canada, and after showing that such defense unions were a success in England, he concluded by outlining the plan of medical defense already in vogue and supported by the St. Francis District Medical Association which he was authorized and prepared to hand over entire to the Association. The discussion of this important matter was deferred until later.

The Question of Medical Education.

Dr. J. R. Jones of Winnipeg delivered the address in medicine. In opening his remarks he referred to the unsolved problems of medical education, the importance of which were especially manifest in view of the establishment of a Dominion Medical Board. Uniform or equivalent curricula, he thought, would greatly facilitate paving the way for the accomplishment of this object. He thought that the great aim of the Association should be to create a Dominion Medical Board upon such a sound and enduring basis that the qualifications could be registered in every province of the Dominion. They should not only be Canadian, but imperial, capable of registration in Great and Greater Britain. There should be no special education for the profession of medicine and the defect in the preliminary education of medical students should be corrected. The standard is not high enough. Many students came into the medical colleges, their minds totally unprepared, undisciplined, not competent to engage in the different studies of a profession with advantage. He quoted from two eminent authorities who favor the retaining of "classical education" as training for professional studies, Dr. Alexander Hill, a member of our own profession and Master of Downing College, Cambridge, and Professor Jebb of Dublin. He referred to medical matriculation examinations and deplored the lamentable defects in the English paper, the most neglected subject in our primary schools. From an experience of many years as an examiner at the University of Manitoba Dr. Jones has concluded that the teaching of English takes a very subordinate position in our schools. The defect was a universal one; and it was obvious that if English should become a prominent subject of medical matriculation examination every student ought to be able to express his thoughts coherently and intelligently. The didactic lecture came in for adverse criticism, and defects and useless wastes of time, which could be more profitably employed, were pointed out. Persistent work in the dissecting room under the guidance of an experienced demonstrator who will describe, discuss, and constantly orally examine the student, is a rational and effective method of teaching anatomy. Medical jurisprudence and sanitary science were not properly taught.

Dr. Jones supported the "case" method of teaching; and from personal experience he favors the English system of clinical clerkships and dresserships as the most feasible, practical and thorough for the development of medical teachings. He referred to the question of Dominion registration and pointed out two serious objections to Dr. Roddick's Bill: 1, the great number of the representatives of the council, entailing expenses beyond, at least, our immediate resources; and 2, the fact that one of the contracting parties to Dominion registration may secede and the elaborate fabric, the work of many years, tumble to the ground.

Dominion Registration.

Dr. T. G. Roddick, of Montreal, who has so long and so ably advocated this much-to-be-desired measure, ably reviewed the subject of Inter-Provincial registration from the time of its inception to the introduction of his Bill at the last session of the House of Commons. The special committee appointed on this subject had not yet reported, so the discussion was postponed until that committee had a chance to meet and report later on in the session. Dr. Roddick now seems to hold to the opinion that the suggestion of Dr. Britton of Toronto, that representation by population, for Ontario at least, would be advisable.

Infectious Pneumonia.

Dr. W. S. Muir, Truro, Nova Scotia, reported four cases, all of which had occurred between April 1 and 13 of this year, in the same house and in the same family. The first occurred in a child of 10 years, the disease terminating by crisis on the sixth day, the child making a good recovery. A sister, age 14 years, contracted the disease; terminated by crisis on the ninth day, but followed two days after by left-sided pleuro-pneumonia. This proved fatal. The third occurred in a sister of 15 years of age, beginning with a pain on the left side and terminating on the tenth day by crisis and recovery. Number four developed pneumonia, but recovery was quick, the patient being about in two weeks. There was no influenza in the town at the time.

President's Address.

Dr. H. H. Chown referred to the work performed in Winnipeg for the purpose of making that city a healthy one, and in spite of the level nature of the land, an excellent system of sewers had been introduced through all the streets; and efficient arrangements had been made for regular flushing of the sewers by means of tilting basins at the upper end of each main sewer. As Winnipeg has two rivers at her door the problem of removing sewage was easily and safely solved. Dr. Chown then referred to the question of tuberculosis and thought that Koch's tentative denial of the oneness of tuberculosis of man and cattle still needs the proof of non-inoculability from cattle to man. He instanced cases of young farmers free from tuberculous taint living in newly-built houses harboring no bacilli and separated by long distances from their neighbors, in whom tuberculosis constantly makes its appearance; and we have here an experiment on a wide scale, and if you can eliminate heredity, house infection and contagion from other cases, to what cause can you describe the origin of these outbreaks?

Epidemic Cerebrospinal Meningitis.

Dr. James McKenty, Gretna, Manitoba, presented this paper, which gave an account of an epidemic occurring in North Dakota during the winter and spring of 1893, within an area extending 50 by 20 miles and was comparatively definitely limited. About 70 persons were seriously ill, and almost as many others suffered from mild manifestations of the disease. Of the 70 cases 25 ended fatally, a mortality of about 35 per cent. In the practice of Dr. McKenty there occurred some 30 cases, a brief record of 22 of these being kept. The average age was 17 years; the youngest fifteen months; the oldest 38 years. The duration of the illness extended from twelve hours to fifteen weeks. No postmortem was made in any case. Dr. McKenty then described in detail the clinical aspects of several cases.

Splenic Anemia, with Case.

Dr. A. J. Macdonnell, Winnipeg, contributed this paper, with the history of the case. In 1898 the number of cases recorded did not exceed thirty, but since that time there have been fifty additional cases reported. Patient aged 27 years; born and lived all his life in Manitoba; family history good; environment good; has never had malaria; habits and mode of life good; positively never had syphilis. The present illness began in August, 1899. Felt heavy on the right side, with a feeling of fulness and weight. In January, 1900, gave up work on account of muscular weakness. There was no vomiting. The patient consulted Dr. Macdonnell in March, 1900, walking into his office with considerable difficulty. There was no enlargement of lymphatic glands. Enlargement of the stomach could never be percussed or palpated. Liver dulness was practically normal. There was no jaundice or pain in the liver region. The patient succumbed to the disease, but no postmortem was held.

Report of Cases Treated with Super-Heated Dry Air.

Dr. W. H. Pepler of Toronto briefly described the apparatus and the method of treatment. It only takes twenty minutes to reach a heat of 300 degrees F. The average duration of the application of the heat is forty-five minutes. The physiological and therapeutical effects noticed were referred to, as dilatation of blood vessels, etc. He administers the treatment one hour after meal time, with due regard that there shall be as little excitement and exertion as possible. He has not seen any ill effects from the treatment. He first gave notes of the case of a patient, a man aged 35 years, who had suffered for some time from varicose ulcer of the right leg, with considerable pain. This patient had a treatment of thirty-five minutes' duration and was able to walk home with very little discomfort. After three times, in ten days, the ulcer was very much reduced in size. The second case was a patient, 22 years of age, who had been troubled with rheumatism for two years past. A temperature of 320 degrees was employed with good satisfaction. Several cases of rheumatism and eczema were reported. The treatment in each case proved highly satisfactory, patients never complaining of any discomfitures and all expressing satisfaction with the treatment. Dr. Pepler subjects a considerable portion of the patient's body from a temperature of 280 to 320 degrees F. The results are often not apparent for some time after treatment.

Orthopedic Treatment of Deformities and Disabilities Resulting from Diseases of the Nervous System.

Dr. B. E. McKenzie of Toronto spoke of disabilities and deformities resulting from paralysis, some of which were commonly regarded as hopeless; but the conditions of a great majority of them were remediable and should receive a considerable amount of attention. He was at some pains to explain the respective motion of joints, particularly the ankle joint and knee joint, especially calling attention to the normal conditions of equilibrium, and then showed how the muscles of some of the groups at times become paralyzed and the balance and equilibrium thereby destroyed. Mechanical treatment was often necessary and often efficacious as well; massage and electricity had their respective places, but he made particular reference to the method of treatment that had been in vogue for twenty years and had been introduced on this continent by Dr. Parish of Philadelphia.

Mild Smallpox.

Dr. G. A. Kennedy, McLeod, Alberta, dealt with the recent outbreak of the disease in the Northwest Territory, an outbreak which was widespread and which had existed for some time before its true nature was recognized. Dr. Patterson, Quarantine Officer for the Dominion Government, was satisfied that there had been 1500 cases. A noteworthy fact was that the greatest number of cases occurred among the French halfbreeds, who had never been vaccinated, and, further, Indians on reserves had not suffered to any great extent, as annual vaccination is the rule. Fifty per cent. of all cases were extremely mild in character; 40 per cent. were cases of typical varioloid; 10 per cent. were severe, almost confluent. The mortality was slight, only thirteen deaths occurring; and the disease prevailed fully as much amongst adults as amongst children.

At the close of this discussion the following resolution was moved by Dr. R. S. Thornton, seconded by Dr. J. L. Bray, and unanimously adopted: "Resolved, That in view of the general prevalence of smallpox throughout the continent, this Association desires to urge upon the profession and the public generally the necessity of vaccination and re-vaccination."

Chronic Ulceration of the Stomach Simulating Cancerous Disease.

Dr. J. F. W. Ross, Toronto, described the case of a woman of 20 years of age, the condition of whose stomach had been bad for three years. She was a nurse in the training school of a hospital and her gastric conditions grew gradually worse. Dr. Ross was asked to see the patient by Dr. E. B. O'Reilly, Hamilton, in December, 1899. He found her emaciated with the opium habit already formed. In January, 1900, rectal alimentation was being persevered in with considerable benefit. In March, 1900, she was discharged from the hospital and remained well for two weeks. As soon as food passed into the stomach great rigidity of the right rectus muscle was noted. When the patient came under Dr. Ross's attention she weighed about 75 pounds. As malignant disease of the stomach is rare at this age of life, it was difficult to diagnose the tumor as such, and the symptoms pointed to the pyloric end of the stomach. It was not possible to say whether cancerous or not. The symptoms pointed to the presence of ulcer, but the thickening easily made out led to the belief that malignant disease had been grafted on to the ulceration. Some dilatation also could be made out, but the rhythmic muscle waves so characteristic of pyloric obstruction could not be found; but large growth was found at the pyloric end. The case was looked upon as hopeless and decision was arrived at not to remove the growth, but to give temporary relief by gastroenterostomy. This was done and the patient made an uninterrupted convalescence. Eleven months after the operation the patient weighed 140 pounds and looked the picture of health. On examination of the abdomen no mass could be felt and the patient was not suffering from any gastric symptoms at all.

Medical Defense.

The report of the Committee on Medical Defense was here presented by W. S. Muir of Truro, Nova Scotia. It reported favorably on the formation of a Medical Union, and the organization thereof was immediately perfected. It will be known as the Medical Protective Association, will be incorporated, and will have for its object the protection of the character and interests of medical practitioners in Canada. It will further promote honorable practice, will aid in suppressing or prosecuting unauthorized practitioners, and will seek to advise and defend or assist in defending members in cases where proceedings involving questions of professional principle or otherwise are brought against them and other like matters. Dr. R. W. Powell of Ottawa was elected president; Dr. McKinnon of Ottawa, secretary, and Dr. James Grant, Jr., of Ottawa, treasurer.

Report of Committee on Dominion Registration.

It is proposed to secure an amendment to the B. N. A. Act, or, to take advantage of section 91 of that Act, and under it obtain legislation from the Dominion parliament, by which the profession in Canada might form a Dominion Council which could be supplemented by legislation by the various provinces recognizing any certificate of standing issued by the Dominion Council as entitling a holder to practice in such provinces. Dr. Muir approved of Dominion registration and spoke for the province of Nova Scotia. Dr. Jones voiced the sentiments of the profession for Manitoba. Drs. A. A. McDonald and J. L. Bray endorsed the scheme for Ontario. Dr. Russell Thomas spoke for Quebec. Dr. Christie said that New Brunswick was in favor of Dominion registration. Dr. Lafferty said the Northwest Territories were favorable.

Varieties and Distribution of Bacillus Diphtheriae and Their Clinical Significance.

Dr. F. F. Westbrcok of the University of Minnesota presented a paper on this subject, primarily from the laboratory point of view. He exhibited a carefully prepared chart showing in tabulated form the results of numerous examinations in schools and stated the conclusions which he deducted from these facts. Formerly, it was believed that the bacillus remained localized at its point of entrance, but now within recent years, however, careful observations have shown that the toxins had been distributed throughout the body and the bacillus itself found in organs far removed from the atrium. From evidences of 230 cases of diphtheria at autopsy, observers had called attention to the frequency with which the bacillus of diphtheria was found in the organs of the body. The bacillus and its toxins have been shown to be capable of producing lesions which differ greatly from each other, as in ulcerative endocarditis, meningitis, etc.

Hairy Tumor from the Stomach Weighing 23 Ounces. Specimen. Recovery.

Dr. H. A. Bruce, Toronto, described this case, a woman aged 26; she had been married six years and had two children. A lump was noticed in the abdomen two months previous to the birth of the last child. Patient had no symptoms. The lump was about 5 inches in width and it could be lifted forwards. It reached to within 3 inches below the umbilicus. It gave the patient no special discomfort, there being absolutely no symptoms present. Dr. Bruce advised exploratory incision. This was done on July 22 last at St. John's Hospital, Toronto. On opening the abdomen in the middle line the spleen and kidneys were found in a normal condition, but there was a large mass in the neighborhood of the stomach. The surgeon could make out the mass lying free in the stomach, a portion extending through the pyloric end of the stomach. An incision was made into the stomach and the tumor removed. After removing the mass of hair, the opening of the stomach was closed in the usual way. Hot salt solution was given for two hours and nutrient enemata for six hours. Twenty-three hours after the operation sips of hot water were given by the mouth. Forty-eight hours after operation patient was given one-half ounce of milk and lime water every hour. She left the hospital on the twentieth day. The tumor was entirely of hair exactly the same color throughout, and the same color as the hair on her head. It was about 24 inches in length, being about 2 inches in diameter at one end and gradually tapering down to a point at the other. Dr. Bruce offered no solution as to how the hair got into the stomach. There were no evidences of hysteria present in the patient. There are some specimens of hairy tumors in the McGill Museum at Montreal.

Case of Transplantation of the Ureter for Cure of Uretero-Vaginal Fistula.

Dr. A. Lapthorn Smith, Montreal, related the case of a married woman, 34 years of age, who came to him on July 1, 1901. During parturition, forceps were employed and the vagina lacerated and ever since there has been a constant flow of urine by the vagina. Operations for her relief had been performed in England without success. Dr. Smith had seen Sanger perform an operation of this character in Leipsic when he was there three years ago, namely, to open the peritoneum running over the large vessels at the brim of the pelvis and to feel for the artery, see the vein and pick up the third tube, which was the ureter. The operation was done in the highest Trendelenburg posture. A very small incision was made in the peritoneum lining the pelvis in the line of the ureter, a silk ligature was passed around it and then the ureter was severed a little above the ligature. The end of the ureter was split open to a distance of a third of an inch. A slit was then made obliquely into the right upper corner of the bladder and the ureter stitched into it, the mucous membrane of the ureter to the mucous membrane of the bladder with very fine chromicized catgut. This is the first time this operation has been done in Canada, and Dr. Smith stated that not a drop of urine had passed through the fistula since.

Syphilis as Seen by the Ophthalmic Surgeon.

Dr. F. Buller, Montreal, said that it often falls to the lot of the ophthalmic surgeon to discover the presence of active syphilitic virus where the disease had long been considered cured, or that the subject cherished the belief that there was no more to fear from it. The ophthalmic surgeon is scarcely, if ever, called upon to treat the disease in the primary stage. The largest share of his work is in connection with the tertiary period, and in this class of cases the disease has been apparently cured for a long period of time. Discussing medication, Dr. Buller does not believe that the protiodid of mercury, at least as ordinarily administered, is a reliable anti-syphilitic. He appears to favor the inunction method first and then gray powder.

The Present Outbreak of Smallpox in America.

Dr. H. M. Bracken, Minnesota, outlined the origin and traced the course of many outbreaks in various parts of the state of Minnesota, with a total of 9429 cases, and the disease has still many centers in that state. It is impossible to locate positively the source of the present widespread epidemic farther than that it spread from the Southern and Southwestern states into North Dakota, Minnesota, Nebraska and Montana. He suggested that it was probably imported into the United States by Cuban refugees before war broke out. Vaccine was frequently spoilt by not being kept in proper temperatures, as it was frequently being shipped in cans which were too hot and subsequently kept in warm offices. The health commissioner of Minneapolis kept all his vaccine in an ice-box, but, of course, not frozen, and had obtained good results. Replying to a question in regard to isolation Dr. Bracken favored eighteen days' quarantine.

Necessity of a Recognition and Isolation of Trachomatous Patients in Canada.

Dr. W. Gordon M. Byers, Montreal, in his paper, recited the history of a young girl from Glengary county, Ontario, who came to the clinic at the Royal Victoria Hospital, Montreal, with a most intense condition of granular lids. She had been unable to open her eyes properly for months past, and her vision was reduced to the counting of fingers. The seriousness of her disease had not been recognized at home, as she mixed freely with other members of the community. Another case was referred to in the County of Leeds, and in this case as well no precautions had ever been taken to prevent the spread of the disease. Dr. Byers believes that there are many unrecognized and untreated cases scattered here and there throughout the Dominion. The disease is said to be prevalent in districts of Manitoba and certain centers in the eastern counties of Ontario and others in Quebec. The trachoma problem has had to be faced by one government in Europe, and the matter has been brought to the attention of the Dominion government, which has not yet taken any action in the matter. Dr. Montizambert stated that the question of exclusion of trachomatous immigrants had been under consideration by the government for some time. He considered these people somewhat undesirable immigrants.

On the Treatment of Typhoid Fever.

Dr. J. L. Bray of Chatham discussed this subject under medicinal, dietetic and hygienic headings. The first he thought might be eliminated except in cases where complications arise, and he thought a certain amount of medicinal treatment useful during the initiary stages. He was in the habit of employing calomel. Tympanites could be avoided to a great extent by a proper diet. In feeding he now gives very little milk, but that little always peptonized. He believes in making the patient drink two or three quarts of pure water in the twenty-four hours. Albumin water with sugar may be given from the first; after the first two weeks he gives liquid peptonoids, or some of the numerous preparations of beef, jellies, mutton broth or a soft-boiled egg.

The Address in Surgery.

Dr. O. M. Jones, Victoria, B. C., opened his address with a reference to surgical diseases in Western Canada as compared with those in the East, and stated that he had often found Western sufferers more impatient, which often demanded severer methods.

A Surgical Procedure for the Relief of Ovarian-Tension Pain.

Dr. Henry Howitt, Guelph, Ontario, read this paper. Is not pain frequently, if not usually, caused by tension on some nerve filament? In Dr. Howitt's opinion the answer should be in the affirmative. The operation Dr. Howitt employs is quite simple. The ovary is exposed and then a number of cross-sections are quickly made through the tense capsule in such a manner as to divide it. Then the larger Graffian follicles are opened. These are merely touched with carbolic acid. If the capsule is thickened a portion should be removed. Hemorrhage has never been troublesome. Adhesions give rise to no complications. Dr. Howitt recited the histories of two or three cases in support of the operation.

Symposium on Tuberculosis.

Prof. Russell of the University of Wisconsin introduced this subject in a paper on human and bovine tuberculosis and their inter-relation. The rapid extension of the disease among cattle within the last few decades has forced upon breeders and dairymen the necessity of considering this subject whether they desire it or not. It is customary in many quarters, even yet, to decry all consideration of this matter as unnecessary, inexpedient, and harmful to the dairy interests. But as is too frequently the case, the motive for such action rests upon a financial foundation, and many breeders are averse to a calm, judicious discussion of the matter simply because it may mean financial loss to them.

The slow, insidious nature of the disease that characterizes it in the human is also to be found in the cattle, and not infrequently an animal may be infected with the seeds of the disease for a considerable time—even a year or so—without showing in any degree physical symptoms that are manifest to even the animal expert. Such animals are not diseased in the ordinary term, i. e., they are not capable of transmitting the disease, either directly or indirectly, through their milk supply or meat. The affection in such cases is latent, generally confined to various lymphatic glands; but animals so affected are, however, potentially dangerous, for the latency of the disease may be overcome through the operation of various factors, and the chronic type may thus be awakened into an acute phase. It is in this way that the disease spreads slowly and unperceived through a herd. Before it has made such inroads as to cause actual death of any considerable number of animals, many more have acquired the trouble, at least in the earlier phases. Necessity of controlling its spread and eradicating it is evident for the sake of the herd itself, if from no other point of view.

Dr. A. J. Richer of Monreal contributed to the next paper on the "Sanitarium Treatment of Tuberculosis." The treatment is made up of rest, outdoor life, overfeeding and medical supervision. This latter was described as the keynote to success in phthisical treatment. Overfeeding was also emphasized.

Dr. Gilbert Gordon of Toronto referred to the "Etiology and the Early Diagnosis of Pulmonary Tuberculosis." He spoke of the early stages of the disease, and thought that we ought to be able to diagnose it before the appearance of the bacilli in the sputum. Direct inheritance he considers very rare. The inhalation of dried sputum is the most direct cause. Dr. Gordon considered that people are woefully behind in Canada in fighting this plague, and more money should be spent by governments and philanthropic individuals in fighting this disease. He went carefully into the symptoms of the pre-tubercular stage and considered that a persistent cough was a very dangerous symptom.

Election of Officers.

These officers were elected for the ensuing year: President, F. J. Shepherd, Montreal; vice presidents: For Prince Edward Island, S. R. Jenkins, Charlottetown; for Nova Scotia, T. F. Macdonald, Hopewell; for New Brunswick, Wm. Christie, St. John; for Quebec, J. Alex. Hutchison; for Ontario, Bruce L. Riordan, Toronto; for Manitoba, A. J. Macdonnell, Winnipeg; for Northwest Territories, H. G. McKid, Calgary; for British Columbia, J. M. Lefevre, Vancouver; general secretary, George Elliott, Toronto; treasurer, H. B. Small, Ottawa. Montreal was selected as the next place of meeting.

Therapeutics.

[It is the aim of this department to aid the general practitioner by giving practical prescriptions and, in brief, methods of treatment for the diseases seen especially in every-day practice. Proper inquiries concerning general formulae and outlines of treatment will be answered in these columns.]

Acne Vulgaris (Blackheads).

According to Dr. E. M. Alger, in *New York Med. Times*, the choice of a local application in the treatment of the foregoing depends largely upon the condition present. Where blackheads are numerous and but few pustules are present the following is recommended by him:

℞.	Hydrarg. bichloridi	gr. ii		12
	Resorcin	ʒiss	6	
	Aq. rosæ q. s. ad	℥iv	128	

M. Sig.: Apply to the face several times daily.

The above should be applied often enough to cause considerable exfoliation of the epidermis, without producing inflammation of the true skin to any extent.

In cases where pustulation is the important feature for treatment, he regards sulphur as far more useful than resorcin. He, under such circumstances, advices the following, the strength of which may be varied to suit the conditions in each individual case:

℞.	Sodii hyposulph.	ʒiv	16
	Sulphuris	ʒi	4
	Aq. rosæ	℥iv	128

M. Sig.: Apply externally as desired.

Caution is given not to use the bichlorid and the sulphur on the skin at the same time. He further states that individual lesions can often be aborted in their infancy by passing into the follicle a blunted needle dipped in carbolic acid, or by painting with pure ichthyol over night. If after this treatment the skin remains rough and dry the following should be applied:

℞.	Resorcin	gr. xx	1	*33*
	Olei theobrom	℥i	32	

M. Sig.: Apply locally at night.

Salve to Remove Corns.

The following combination in the form of a salve is recommended for the removal of corns:

℞.	Pulv. plumbi acetatis		
	Pulv. myrrhæ		
	Pulv. camphoræ		
	Plumbi oxidi āā	ʒi	4
	Olei olivæ		
	Petrolati āā q. s. to make paste.		

Misce. Sig.: For local application; or:

℞.	Acidi salicylici	ʒss	2
	Acidi lactici	ʒss	2
	Ext. cannabis indicæ	ʒiv	16

M. Sig.: Use as a local application in treatment of corns.

Treatment of Scarlatinal Nephritis.

Dr. Charles G. Kerley, as noted in *Med. News*, states that every case of scarlatina, whether mild or severe, ought to be treated as if nephritis were to be expected. A child with scarlet fever is to be considered ill for five or six weeks, even if no complications are present. The nephritis, if present, is too often overtreated by the physician. He deprecates the heroic use of drugs like digitalis and pilocarpin, which are too often indiscriminately prescribed, as well as irritant cathartics and the diuretic salts of potassium. He recommends, first of all, a light diet, the relief of constipation with small doses of calomel; small doses of aconite, ¼ minim of the tincture every two hours to a child of 3 years, to promote diaphoresis and diuresis. He also recommends colonic flushings, employing the normal saline solution at a temperature of 110 F. A child of 3 years should be given 16 to 24 ounces of the solution, to be retained and repeated every six or eight hours. The child should be kept in bed until the urine has been normal for two weeks.

Camphor in the Treatment of Varicose Ulcers.

Attention has been called to the value of camphor dressings in promoting cicatrization of varicose ulcers of the legs by the *Med. Press;* especially is this dressing adaptable in ulcers which are very refractory to treatment. An ointment made up similar to the following is recommended:

℞.	Pulv. camphoræ	gr. v		30
	Zinci oxidi	gr. l	3	30
	Adipis q. s. ad	ʒiv	16	

M. Sig.: Apply locally.

If this should be found to be too irritating the following should be applied in its stead:

℞.	Camphoræ	gr. vi		36
	Zinci oxidi	ʒii	8	
	Olei olivæ	ʒiiss	10	

M. Sig.: Apply locally.

An alternative application is a solution of camphor in spirit, but this should be applied only after the ulcerated surface has been thoroughly cleaned of scabs and crusts by poultices. It is asserted that complete healing of the ulcer will take place within three weeks.

For the Obstinate Diarrhea of Tuberculosis.

The following combination containing ichthoform is recommended in the treatment of tubercular diarrhea:

℞.	Ichthoformi	gr. v		33
	Tannalbin	gr. x		66
	Bismuthi subgal.	gr. x		66
	Codeinæ	gr. ¼		015
	Olei menth. pip.	m. ¼		015

M. Ft. Chart. No. i. Sig.: One such powder every two to six hours.

Treatment of Cystitis.

Howland, in *Med. News*, states that cystitis is always caused by the presence of micro-organisms, chiefly the colon bacillus, streptococcus pyogenes and staphylococcus pyogenes. In the treatment of acute cystitis, he advises rest in bed, the use of opium and belladonna, either by the mouth or in the form of a suppository. In severe cases he instils into the deep urethra a few drops of a 4 per cent. solution of cocain. He does not recommend any local treatment to the bladder. In the chronic form he irrigates the bladder daily with solutions of salicylic acid, nitrates of silver or mercury bichlorid. Internally he employs urotropin in 7-grain doses as an antiseptic.

Alcohol Compresses in Appendicitis.

Prof. Filatoff, in *Rev. de Ther.*, has used with success alcohol compresses in appendicitis. A gauze compress folded four times and large enough to cover the whole abdomen is soaked in a 95 per cent. solution of alcohol and lightly squeezed before being applied to the abdomen. When applied, a piece of flannel should cover the gauze and an ice bag placed over this. The gauze compress should be changed when the alcohol has evaporated. Opium should be given internally at the same time.

Treatment of Acute Eczema.

Dr. R. Lederman, in *Kan. City Med. Rec.*, states that the best results are obtained by the free application of dusting powder during the erythematous and early papular stages. He considers zinc, bismuth, aluminum and dermatol as the best. For the itching he recommends a lotion similar to the following:

℞.	Thymol	gr. i		06
	Aq. rosæ	℥i	32	

M. Sig.: Apply locally before using the dusting powder.

When crusts have formed he uses a paste of salicylic acid in olive oil or, what he considers even better, the following:

℞.	Zinci oxidi	ʒss	2	
	Bismuthi subnit.	ʒss	2	
	Ung. aq. rosæ	ʒii	8	
	Ung. simplicis	ʒii	8	

M. Sig.: For local application.

For the chronic form, salicylic acid should be used in the form of an ointment of 5 or 10 per cent. strength.

Treatment of Acute Coryza.

The *Archiv. fur Laryngologie* recommends orthoform as a valuable drug in abating the symptoms and cutting short the attack. The following combination is used in the form of an insufflation:

℞.	Orthoformi	ʒii	8	
	Sodii-sozoiodol	ʒii	8	

M. Sig.: Use in the form of an insufflation to cover the membranes of the nasal fossæ and posterior nares.

This should be repeated several times a day until the local symptoms have subsided. The effect of the orthoform is to produce a certain amount of anesthesia of the membranes and to reduce the congestion. In this way the local inflammation may be aborted. The sooner the treatment is begun the better.

Treatment of Paralysis Agitans.

The cure of paralysis agitans is hopeless, but Dr. R. L. Williamson, in *Med. Chronicle*, considers a number of methods he has tried for the relief of the more pronounced symptoms. He has found no virtue in any treatment by drugs, except in the use of hyoscin hydrobromate, duboisin sulphate and hyoscyamin hydrobromate. He recommends that the first of these preparations be used in doses not to exceed grain 1/150 each, dissolved in aqua chloroformi. The dose may be increased to 1/100 grain in some cases, when no toxic symptoms have appeared. If hyoscin fails to relieve the tremor he suggests the use of duboisin sulphate, which as a rule is not so efficient as the former.

The following is employed hypodermically by M. Bourneville in the treatment of paralysis agitans:

R.	Liq. potass. arsenitis	ʒii	8	
	Glycerini (neutral)			
	Aq. destil. āā	ʒi	4	

M. Sig.: Inject fifteen minims hypodermically.

Treatment of Tuberculous Peritonitis.

I. Burney Yeo, in *New York Med. Record*, states that he has seen good results follow the internal administration of iodoform gr. ¼ and creosote m. ½ and the application to the surface of the abdomen of an ointment as follows:

℞.	Ung. iodoformi (10 per cent.)			
	Olei morrhuæ āā	℥i	32	

M. Sig.: Apply locally to the abdomen twice daily.

He states that the best results are obtained in the early stages and in those where there is more or less ascitic fluid. In the advanced chronic cases with induration of the various intestinal coats, adhesion of the coils of the bowel to each other, large caseous mesenteric glands, neither surgical nor medical treatment offer much. He believes, however, that if iodoform is rubbed into the skin of the abdomen in a young person, it rapidly enters the circulation and is eliminated and detected in the secretions including the secretions of the serous cavities and therefore reaches the location and seat of the tubercular deposit.

To allay the pain and irritation of the bowels a mixture containing the following was prescribed:

℞.	Bismuthi salicylatis	gr. xv	1
	Spts. chloroformi	m. xv	1
	Tinct. card. comp.	ʒi	4

M. Sig.: At one dose to be repeated in six hours.

Treatment of Meningitis.

Dr. Daniel R. Brower, in an article on treatment of tuberculous meningitis, gives most satisfactory results obtained from the use of the following:

℞.	Iodoformi	ʒi	4
	Lanolini	℥i	32

M. Ft. Ung. Sig.: Apply locally to the scalp.

Before applying this ointment the head must be closely shaved and the ointment thoroughly rubbed in, after which the ice-cap can be applied. The iodin reaction in the secretions can be obtained within a very few minutes after the ointment has been applied. His percentage of recoveries indicates that there is virtue in this method of treatment.

Medicolegal.

One Thousand Dollars for Breaking of Leg.—The Supreme Court of New Jersey holds, in the case of Wiezynski vs. the American Sugar Refining Company, that an award of $1000 for the breaking of the leg of an employee, a Pole, who was engaged in receiving bags of crude sugar thrown down to be loaded on trucks, was not unreasonable.

Twenty-Five Thousand Dollars Too Large an Award.—The Supreme Court of Mississippi holds it impossible to sustain a verdict for $25,000 in the appeal of the Cumberland Telephone & Telegraph Company vs. Pitchford. Here a lineman, 22 years of age, was thrown to the ground by coming into contact with a live wire while up a telephone pole. His spinal column was fractured, and he was paralyzed from the waist down. The attending physician stated that he found him in a condition of profound shock, and that he suffered considerably up to within 24 hours of his death, which occurred two weeks after the accident. The court holds $12,500 to be a sufficient amount of damages to allow in the case.

Data Required to Recover for Medical Services.—In St. Louis Southwestern Railway Company of Texas vs. Stonecypher, an action brought by the latter party to recover for personal injuries, it was averred that it had been necessary for him to incur an expense of $100 for doctors' bills and medical treatment; $40 to one physician named, and $60 to another, and that the amount charged by each of the physicians was a reasonable charge for the services. Exception was taken because the dates and place at which the alleged services were rendered were not also stated. But the Court of Civil Appeals of Texas sees no error in the overruling of the exception. It says, that the party was suing for the amount that the company had caused him to pay for doctors' bills and medical treatment, and it was not incumbent upon him to more specifically set out his claim. He was not suing on account, where he had performed services at different times and places, but was suing for an amount that he was compelled to pay by reason of the company's negligence. The case would have been different had the doctor been suing to recover the amount of his bill. In such case it would have been necessary for him to have itemized his account.

Statements of Injured Persons as to Past Suffering.—The Court of Civil Appeals of Texas says, in St. Louis Southwestern Railway Company of Texas vs. Martin, that the declarations of a person suffering pain are admissible in evidence, but must be expressions or complaints made at the time, and the natural and instinctive manifestations of pain and suffering. But the same principle does not apply to statements made to an attending physician, because he testifies as an expert, and his opinion must be based upon data furnished him. Again, it says that statements made to a physician as to symptoms and past suffering are no more admissible as evidence in favor of the injured party in a personal injury case than if they had been made to some other person. They are only admissible for his information, in order to enable him to form an opinion. If they are made to him in the course of treatment, they come within the exception. But, when the physician has been employed by the plaintiff to make the examination for the purpose of testifying in the case, such statements, it holds, should not be admitted.

Liability for Injury of Property by Pest House.—The Court of Appeals of Kentucky holds, in City of Paducah vs. Allen, that, where a city or other municipality erects and maintains a public institution, such as a hospital for the treatment of smallpox or eruptive diseases, which, by reason of its nature, endangers the lives or health of the occupants of adjacent premises, as by subjecting them to contagious or infectious diseases, it is not only a nuisance, but it is such an invasion of the property rights of such adjacent holder or holders as amounts both to an injuring and a taking of property, under the provision of the state constitution which requires that just compensation must be made for private property taken, injured, or destroyed, for public use. The measure of damages to which an adjacent owner will be entitled, if the establishment of such a hospital or pest house is permanent, the court holds, will be the amount that the market value of his property is impaired thereby. Nor does the court consider that it will be rendered otherwise by the fact that medical witnesses testify that there is no actual danger of the disease being contracted by persons on such adjacent property. For example, it holds in this case that there was such an invasion of the property rights of an adjoining owner as to entitle him to recover for the depreciation of the market value of his property, although the hospital or pest house in question was located about 250 yards from his fence, and about one-half mile from his residence.

Board of Health Can Not Be Controlled by Injunction.—The Supreme Judicial Court of Massachusetts holds, in the case of Stone vs. Heath, that the board of health of a town can not be restrained, either under the general equity power vested in the Superior court, or otherwise, from entering on premises where it has adjudged that a nuisance exists, and abating the alleged nuisance, if the owners of the property do not abate it as ordered, and that it can not be restrained from instituting proceedings against such owners on account of their failure or neglect to comply with the order of abatement. The jurisdiction conferred by the statute, it says, is summary in its nature, and the objects to be attained by its exercise would be defeated in many, if not most, cases, if the orders of boards of health were subject to judicial examination and revision at the instance of parties affected by them before they could be carried into effect. The decision of the board of health is not, however, in such cases final and conclusive to all purposes in regard to the parties interested on the question whether the thing complained of was a nuisance. It establishes, for the time being, that there is a nuisance, and those who act under the orders of the board of health in abating it are protected thereby while engaged in the performance of the duty thus imposed. But they act at their peril if it turns out in subsequent proceedings that there was in fact and in law no nuisance. And the question whether there was a nuisance, or whether, if there was one, it was caused or maintained by the parties charged therewith, may be litigated by such parties in proceedings instituted against them to recover the expense of the abatement, or may be litigated by the parties whose property has been injured or destroyed in proceedings instituted by them to recover for such loss or damage, and may also be litigated by parties charged with causing or maintaining the nuisance in proceedings instituted against them for neglect or failure to comply with the orders of the board of health directing them to abate the same. A board of health having adjudged that a nuisance exists, the question of what influences or motives may have set the board in motion, the court holds, is immaterial.

AMERICAN.

1. **Metastatic Choroiditis.**—The disease, as presented in the six cases here reported, is characterized by pain in the head and eyes, intense vascular congestion, and the usual symptoms of choroiditis and irido-choroiditis, and results in a rapid and total loss of sight. Severe headaches and fever may precede it, and the intraocular tension is at first increased, but subsequently sinks much below normal, even when no perforation of the eye-ball occurs. The course of the disease is from three to six weeks, and the prognosis is always bad, the case ending in total blindness with sunken eye-ball. Enucleation is not advisable in the acute stage, especially if Tenon's capsule and the orbital tissues are involved. Bull discusses the theories of this metastasis, especially referring to Goh's article on the subject, and he doubts whether the occurrence of metastatic ophthalmia signifies a particularly severe type of the general disease causing it, since as a symptom it has not the prognostic significance for the original condition that would, in such cases, be expected.

2. **Protozoal Life in the Blood.**—Overholzer reviews the various facts in regard to the appearance of the lower forms of animal life in human and other blood, with special reference to malaria. He makes the practical point that in his section of the country, the so-called intestinal colic of babies under six months and older, is often more benefited by quinin than by all the food modifications or remedies that have been suggested. He has no doubt but that in these cases microscopic examination of the blood would show the true etiological factor of the condition.

3. **Infant Feeding.**—The subject of infant feeding is discussed by Kerley, who criticises the use of set formulæ, as they do not make distinction as to the food strength in different seasons of the year. In the hot months the infant's digestive capacity is lessened. There is but one substitute for breast milk, and that is cow's milk, and the important point is to combine it in such a manner as to give the strength of fat, sugar and proteid normally found in mother's milk. He says: Beginning with the feeding of the child at birth, for the first three days one-half per cent. of sugar-water mixture is given; after the third day a milk mixture containing 1. of fat, .4 proteid, 4.5 sugar; after the tenth day 1.5 fat, .7 proteid, 5. sugar; after the twenty-first day 2. fat, .8 proteid, and 5. sugar. The increase is very gradual, so that when the average child is six months old he will receive .3 to 3.5 of fat, 1. to 1.5 of proteid, and 7. of sugar. A very weak strength is given at first, which is increased if the child thrives. The baby is weighed every two or three days, and the stools are examined daily for signs of indigestion. The fat, proteid, and sugar are independently increased or diminished as may be indicated by the stools and the condition of the patient. When this method of low feeding is followed at birth, it is, with very few exceptions, followed by success. The usual error is in beginning with too strong a mixture, and in inattention to the case. For aiding in the digestion of casein, two methods have their advocates. One is the peptonizing of the milk, and the other the use of cereals. The former in his hands is of no value except when completely peptonized milk is introduced directly into the stomach or rectum. Partially peptonized milk is an impossibility. Cereals he finds valuable as diluents and for the nutrition they furnish, but he has never been able to increase the proteids in a case of proteid incapacity. He gives details of the management of difficult cases and reports two cases of the rare condition of idiosyncrasy where cow's milk can not be borne at all.

4. **Intestinal Obstructions.**—This not infrequent condition is treated of by Lilienthal, who attributes part of its increase to the increased frequency of abdominal section, but thinks also that true ileus is often due to appendicitis. He cautions against mistaking the expulsion of air introduced by enema for the expulsion of flatus and suggests that the physician himself conduct the administration of the enema for this reason. Sudden abdominal cramp-like pain with vomiting but no fever, should be treated by enema and in the adult by a small dose of morphin (Treves). If permanent relief does not follow, the case is a suspicious one, and operation is indicated. The medical treatment of intestinal obstruction is safe no longer than until the diagnosis is made. After that, the earlier the operation, the better the chances. Some interesting recoveries, however, have been reported with the use of atropin, which may have its utility as an antispasmodic, and a tonic in paralytic obstruction. The suggestion of Vidal of the serum treatment is mentioned, but Lilienthal thinks that its utility must be limited to cases where operation has been already performed, and the symptoms have not subsided. This treatment should never supersede surgery. He advises washing out the stomach before the operation, and in desperate cases abstinence from general anesthesia. The incision should be small at first, and enlarged if necessary. If strangulation exists, it must be relieved before the patient leaves the table, and the possibility of more than one obstruction should be kept in mind. Enterostomy or colostomy should be performed when a prolonged operation would entail the gravest danger of death. In making an artificial anus, one must be sure that the opening is above the occlusion. Gangrenous intestines must be at once resected. When there is great distension of the small intestines, a number of small incisions opposite the mesentery should be made for evacuation of the gut, before searching for the obstruction. The author has practiced this for four years, and feels justified in continuing it. There is rarely, if ever, any advantage in the administration of a cathartic after the strangulation has been relieved. Surgery, and surgery alone, he believes can logically furnish relief in acute intestinal obstruction.

5. **Antitoxin.**—Rupp's article is an unfavorable criticism of the antitoxin therapy, which, he thinks, has a very limited utility.

7.—See Journal, July 7, p. 135.

8. **Saddle-Nose.**—E. J. Senn prefers an external excision in the treatment of saddle-nose, refracturing the bones at a definite point, and removing any excess of callus in traumatic cases. He advises the following operation: A vertical excision one and a half to two inches in the middle line of the nose over the depression, carefully dissecting back the skin and soft structures. With a narrow chisel, the nasal bones are frac-

tured at the point where they join the nasal process of the superior maxillary, care being taken not to injure the mucous membrane. A Kocher director, covered with gauze, is now passed into each nostril alternately, the fragments mobilized and the nose molded into the proper shape. A straight needle, armed with a medium-sized silver wire, is passed through the nose transversely underneath the fragments. Lead discs are placed at each end. The wire is tightened and fixed on the discs, thus supporting the fragments, and also narrowing the nose to any desired degree. He suggests the use of cork instead of lead to avoid pressure necrosis. Next, rubber tubes of the desired caliber are placed in the nostrils to facilitate breathing and to act as an intra-nasal splint, retained by adhesive strips fastened to the cheek. A plastic splint is made to conform the new bridge, with hygroscopic gauze and plaster-of-Paris, molded to the nose and held there until it sets. It should reach from the root of the nose to the lower border of the nasal bones, and should be retained by adhesive strips. After the operation the patient should be watched carefully, the tubes frequently removed and the cavities cleansed. The silver wire should be removed at the end of five or six days, the tubes and casts in fifteen to eighteen days. He gives illustrative cases showing the success of the operation.

9. **Pulmonary Tuberculosis in Life Insurance.**—The following conclusions are offered by Greene: 1. The present requirements of a majority of our insurance companies and the usual methods of insurance examiners are not sufficient to exclude persons suffering from incipient or arrested tuberculosis. 2. Improper preparation of the patient is a fertile source of error, and should be covered by specific instructions and direct inquiry, as is now done in but few instances. 3. Light weight in an applicant should lead to a careful scrutiny in every case, and suggests an afternoon appointment for temperature determination. Many accepted as sound light weights are actually cases of incipient or arrested tuberculosis. 4. Heavy weights can not be accepted at their face value. 5. Recent loss of weight is suggestive and important. It is important that the "best" weight should be stated. No blank known to the writer contains the latter inquiry. 6. Hoarseness should arouse suspicion, and be met by postponement until recovery. 7. The determination of the body temperature is extremely important and its present neglect inexplicable. 8. The physical signs of tuberculosis are obscure and require skill and judgment, both in their detection and the weighing of their importance. The proper attitude, viz., demonstration of the normal, greatly simplifies matters. Hence: 9. A knowledge of the normal chest is all important. 10. Unilateral hyperresonance is as important as unilateral dulness, and absence of the normal breath sounds no less significant than the presence of abnormal sounds. 11. Broadly speaking, the examiner must rely more upon auscultation than percussion. No one sign available to the insurance examiner is pathognomonic, and hasty conclusions are deplorable and disastrous. 12. The tuberculin reaction and demonstration of tubercle bacilli in sputum are impracticable measures, save in the case of substandard lives. 13. Greater stress should be laid upon the question of direct infection, and specific questions in relation to environment should be inserted in every medical blank.

10. **Antitoxin in Diphtheria.**—The subject of antitoxin and its value in diphtheria is noted by Griess, who offers the following in conclusion: 1. Antitoxin should always be given as soon as the diagnosis is made with certainty. 2. Children require larger doses, as their natural resources for fighting disease are always less than those of adults. 3. In mild cases of diphtheria 2000 units should be given as an initial dose, and if no improvement takes place within 12 hours, it should be repeated. 4. All laryngeal cases, or cases in which prostration is severe, should have 4000 units as an initial dose, and 2000 units in 8 or 12 hours if there is no marked improvement. 5. Intubation in children should be practiced before the child becomes exhausted, and if it is not successful, no time should be lost in making a tracheotomy. Before performing either of these operations, however, a stimulant should be administered as the shock during these operations is very great. More than one child has been saved by a hypodermic injection of ether, injected when the patient was apparently dead, after the trachea had been opened; this, together with artificial respiration, caused the child to soon show signs of life. 6. The results to be expected from antitoxin depend especially upon two things: When used in the course of the disease (late or early), and in what type or class of cases it is employed.

15. **Gastric Ulcer.**—Cabot reviews the surgical treatment of gastric ulcer and its present status, which he states as follows: 1. Acute hemorrhages should rarely be treated by operation; the results of interference have not been good, while the results of medical treatment have been satisfactory. When, however, a hemorrhage frequently repeats itself, even if severe in amount, it will demand operative treatment as soon as its recurrent character is plain. 2. Small, frequent hemorrhages, threatening anemia, give a clear indication for operation. 3. Perforation of the stomach, either acute with general peritonitis, or chronic with surrounding adhesions and perigastritis, demands instant operation. 4. When an ulcer runs a chronic course with a strong tendency to recurrence, and gradually diminishes the patient's capacity for work and for the enjoyment of life, an operation is indicated, especially when the patient is so situated as to be dependent on his daily work for support and unable to closely regulate his diet.

16. **Intestinal Cancer.**—The operations indicated for intestinal cancer are stated by Lund as follows: Operation is indicated absolutely in all cases in which the tumor is suspected of being a cancer of the intestines after careful eliminative diagnosis. If a benign tumor or obstruction is found, so much the better. It is also indicated when the symptoms point to the possibility of stenosis, whether it is palpable or not. Exploratory operation is indicated whenever vague intestinal symptoms, associated with a loss of weight, in persons past middle life suggests intestinal cancer. Exceptions should be made of cases of general peritoneal metastases, hepatic cancer, etc., where no radical operation can be performed, and only palliative measures are suitable. In regard to the nature of the operation, this has to be determined in each individual case. Excision of the growth and immediate union of the ends of the bowel is the ideal.

17. **Hip Disease.**—A case of acetabular disease of the hip, in which amputation of the joint seemed indicated, but was refused, was treated by Bradford by throwing the head of the femur out of joint by an incision similar to that for excision and placing it on the dorsum of the ilium. A free incision was made, allowing drainage from the acetabulum, which was found perforated. A celluloid drainage tube one inch in diameter was inserted to a sufficient depth and secured by a stitch. The base of the acetabulum was touched with carbolic crystals and washed off with alcohol. The limb was fixed in flexion and adduction by a plaster-of-Paris spica. Marked improvement followed. Drainage was kept up for six months, and then the boy was allowed to go about. The tubercular osteitis of the acetabulum has been healed and a future operation may correct the present deformity.

19. **Sweat Baths, Etc.**—Friedlander has experimented on himself and others with various forms of sweat baths, and baths that increase bodily temperature, such as the Russian steam bath, and gives the indications for either variety as follows: He prefers [illegible] baths. 1. In combating infectious an[illegible] acute and subacute diseases due to exposure, catarrh of the upper respiratory passages, fresh rheumatic affections of the muscles and joints, and also in other infections, the onset of which is not characterized by high fever and in which individual conditions render an increase of the fever permissible and desirable for the course of the pathological process. Furthermore in syphilis, and in a general gonorrheal infection. 2. When an intense increase of metabolism is indicated from other causes, such as autointoxication, and in conditions affecting metabolism, like gout.

On the other hand, he favors sweat baths: 1. When a cure by means of free diaphoresis is contemplated; in exudations and transudations, in nephritis with edema, in hydremia and chlorosis, in metallic poisoning, and in obesity as an adjunct to other methods of treatment. 2. When chronic inflammatory processes are to be influenced by peripheral hyperemia. In chronic and especially rheumatic affections of the muscles, joints and nerves, in the residual conditions of acute articular rheumatism, in chronic muscular rheumatism and arthritis deformans, in neuritides, and in tubercular arthritic affections.

22. **Formic Aldehyde in Tuberculosis.**—Formic aldehyde has been employed by Muthu in two ways, by the dry method, in which the tabloids are placed over a methylated spirit lamp and volatilized, and the moist method, in which, together with this, there is steam mixed with the formaldehyde vapor, rendering it more diffusible and efficacious. The gas is used either by suffusion throughout the atmosphere, or when in the aqueous solution, it is employed in an inhaler or nebulizer. He has used it with 15 patients from three to five months. Five, all men, were completely cured; seven, six men and one woman, were almost cured, that is, though the symptoms did not completely disappear, and a few bacilli remained, they have been able to go back to their former occupations. and have been in good general health; one, a woman, was slightly benefited, and in the remaining two there was no effect. Of the five who were completely restored, three had affection of one lung, one had a large cavity in one lung, and the other had marked signs of breaking down in both lungs. Of the seven nearly cured, two had cavities in one lung, and consolidation of the other; one had empyema complicating pulmonary tuberculosis, and the rest had more or less extensive affections of both lungs. He believes that the treatment should be given a fair trial in every sanitarium, systematically and persistently used by some one who is careful and enthusiastic.

24. **Cystitis Pyelitis and Pyelonephritis in Women.**—From a study of the pathology, bacteriology and symptoms of cystitis, pyelitis and pyelonephritis in women Brown comes to the following conclusions: 1. The great majority of cases of pyelitis, pyelonephritis, and cystitis are due to infection with various micro-organisms (of which the colon bacillus is the commonest) which may reach the kidney or bladder either exogenously or endogenously. 2. In the majority of cases the condition either can be prevented or can be cured if the conditions underlying its development are recognized and understood, and the correct measures inaugurated. 3. There are various conditions, such as urinary hyperacidity, which may simulate almost exactly true vesical infections, and yet in which misinterpretation and improper treatment may lead to the development of a true cystitis and its deplorable consequences. 4. In no condition is prophylaxis more essential than in that of the infections of the urinary tract, while to be able to prevent such conditions, we must have constantly before us the danger of the development of infection in all cases associated with conditions which tend to lower the general resistance of the patient, and also those which render the bladder susceptible to infection, especially by the trauma of an operation or catheterism. 5. While an absolute diagnosis of renal infection can be made only by ureteral catheterism, in the majority of cases a very probable diagnosis may be arrived at by a consideration of the relation between the grade of albuminuria and pyuria and by careful cystoscopic examination of the bladder, especially that portion about the ureteral orifices, and the character of the urine *flowing therefrom*. 6. Contrary to the opinion expressed in the majority of textbooks, a great majority of the infections both *of the bladder* and of the kidney are associated with acidity of *the urine*—that is, are due to micro-organisms which do not split up the urea. 7. Probably *in the* majority if not in all the cases of renal infection due to a urea-decomposing micro-organism, after the condition has lasted for a certain length of time, a stone is formed by the decomposition of the precipitated salts about the bacteria as a nucleus. 8. To be able to thoroughly understand the cases of cystitis, pyelitis, and pyelonephritis, to make the proper diagnosis to inaugurate and carry out a rational line of treatment, to be conversant with the proper means of prophylaxis, and to give a correct prognosis, a careful chemical, microscopical, and bacteriological study of the urine is absolutely essential. See also 53.

25. Eskridge's article is to be continued, and will be noted later.

26. **Esophagometer, or the Intragastric Whistle.**—After first noticing the variations of the estimates of the length of the esophagus and the position of the cardia, which are quite noticeable, Spivak gives his reasons for assuming a practical value in ascertaining these data. It is important to know how much rubber tubing should be allowed to enter the stomach in severe gastric lesions, and the diagnosis of gastrectasis and gastroptosis largely depends on the proper location of the cardia. He then describes his instrument, which consists of a stomach tube, provided at the proximal end with a whistle, which is inserted in such a way that the opening through which the air is blown in looks towards the distal end, and the opening at which the air makes its exit is in apposition with the side opening of the tube. The tube is introduced into the esophagus and air blown in. As long as the whistle traverses the esophagus, no sound is heard, but as soon as the cardia is reached, a distinct whistle is heard. In this way the exact length of the esophagus is ascertained. The advantages of the device are given as follows: 1. Precision in measurement not attainable by any of the other methods, except by that of Purjesz. 2. Cheapness. The materials necessary for manufacturing this instrument are a stomach tube, whistle, and a piece of thread. It does not take more than two minutes to insert and secure the whistle in the tube. 3. No special instrument is needed. It is an esophagometer only when used for the purpose of esophagometry. In the twinkling of an eye the component parts are separated and the stomach tube and whistle are ready for other uses.

27. **Dupuytren's Contraction of the Palmar Fascia.**—Noble Smith discusses the etiology of Dupuytren's contraction, and reports a case in which he believes he observed it in its very early stages. In a man aged fifty a small nodule developed subcutaneously at the base of the ring finger on the left hand. The first symptom was pain, and was followed by the characteristic slight contraction of the palmar fascia. There was no history of gout in the family, but a slight tendency to muscular rheumatism and to bilious attacks, so-called. A full dose of Pil. cathart. comp. U. S. P. was given, followed by relief of the pain and subsidence of the nodule. After several repetitions of the treatment it entirely disappeared and there has been no apparent tendency to recur.

28. **Nasal Stenosis.**—Porcher calls attention to the varied symptoms from nasal stenosis, and reports several cases of cough, deafness, abscess of the ear, etc., apparently relieved by nasal operation. He also refers to still more extraordinary reflex phenomena reported by Schiff and Gomperz, already abstracted in The Journal.

29. **Atrophic Rhinitis.**—From his studies on the subject Seiler finds atrophic rhinitis most frequent in American-born males of Irish parents, next in Irish born, then Italian born, French and German, while the smallest contingent is furnished by the negro race. He also finds that occupation seems to have very little to do with its occurrence, excepting in special case of employes working in chemicals. The treatment which he finds best has been the removal of the dried secretions by gradual solution and loosening with liquid solvent, to which should be added some of the ethereal antiseptics, the formula for which is embodied in the Seiler antiseptic tablets. After removing the scabs and ozena, he employs the Goldstein cotton nasal plug, with the nitrate of silver and stearate of zinc.

31. **Gastrectasis.**—The deductions which Cordier draws from the study of the operative treatment of gastrectasis are, that cancer of the pylorus, even though removed, returns quickly, and is always fatal and that pylorectomy is attended

by high mortality and is not a justifiable procedure in advanced pyloric carcinoma. Gastrectasis, due to a malignant closure of the pylorus, is best treated by gastro-jejunostomy, according to Woelfler's or Von Hacker's method. It is not necessary to twist the bowel in making the anastomosis to prevent the bile from entering the stomach. The anastomotic opening in the stomach should be at the most dependent point of the dilated organ. The operation is attended by a low mortality, and should be performed whenever marked dilatation of the stomach, with emaciation, pain and invalidism is present. Relief follows at once, and the patient gains in weight, and, if no malignant disease is present, is restored to former health.

32. **Tracheal Injection.**—Thompson has found special benefit from tracheal injections and has come to use them largely in his practice. The technic is as follows: The larynx is illuminated as usual. The patient holds his own tongue while the physician guides a properly curved laryngeal syringe back over the glottis. Then, while the patient takes a slow full inspiration, the medicine is injected between the cords and into the trachea. It is not necessary to touch any part of the larynx, and if the patient will follow directions, the operation is easy. It is only with a few who have very little self-control that this method is impossible. The advantages are the direct local action of the medicine, and its quick constitutional effect from being injected directly into the lungs. It also undergoes no chemical changes before it reaches the spot. He advises this method in the late stages of bronchitis, in chronic bronchitis, asthma, pulmonary emphysema and chronic inflammation of the trachea. The most effective medicines are those that are volatilized slowly by the temperature of the body, such as menthol, camphor, creosote and guaiacol carbonates and chlorophenol. He says the longer he employs the method, the greater is his opinion of its value.

34. **Blood Examinations.**—The value of blood examinations in surgical diagnosis, the leucocytosis of shock, and the necessity of a careful blood examination before general anesthesia are first noted by Bloodgood. The blood-count may enable us to detect and gauge a hemorrhage, and he finds that the dangers from an anesthetic are greatly increased with a hemoglobin estimate below 50 per cent. There is need of more study as regards post-operative leucocytosis; a sudden rise may indicate complications. The most certain value is in the early recognition of intestinal obstruction, in which there is always a rise of usually over 20,000. In a few cases of post-operative phlebitis there was a rise in the leucocytes ranging from 15,000 to 20,000. This has been frequently observed in typhoid phlebitis, but, on the whole, the observations of the changes in the leucocytes after operation are not well established. The principal theme of the paper, however, is the importance of the leucocyte-count in the early recognition of acute abdominal lesions, *appendicitis, etc.* A tabulated statement of the counts in different phases of the conditions, acute, chronic, abscess, etc., is given and several cases illustrating certain points are reported in detail. While there is need of more observations before definite conclusions can be reached, these are enough to make a careful surgeon insist on a blood-count in every case of acute abdominal lesion, and even every four to six hours during the first two days. He says, "A rapid rise in the leucocytes, especially above 18,000, should be a sufficient indication for exploration, even in those cases where the local symptoms are very slight. In the few exceptions in which the local symptoms are sufficiently distinct to indicate an operation, a low leucocytosis should not influence as to delay operation." The article concludes with remarks on the leucocytosis of intestinal obstruction and cholecystitis, in both of which there is a significant rise.

35. **Hysteria.**—Ullman recognizes a special susceptibility to hysteria in certain races, especially the Jews; the Latins and Slavs are also to be regarded as hysterical. It appears to be frequent in the negro, and under civilization is appearing in the North American Indians. He concludes that no race is free and its greater frequency in some is attributable rather to environment than to special racial peculiarity.

40. **Medical Education in Japan.**—The medical universities of Japan are described by Ikeuchi. The medical education is given in that country by the Tokyo and Kioto Imperial universities, the medical departments of the high schools in five provinces, the Kioto, Osaka, and Aichi provincial medical schools, and two private medical colleges. Besides these are the Naval and Army medical academies in Tokyo, which do not educate the student, but instruct the surgeon-probationers and surgeons who are put on service out of easy reach of the scientific world. The first two are government institutions with a medical course of four years, ample clinical advantages and post-graduate courses. The medical departments of the five high schools differ more or less. They also have four-year courses. He gives a summary of the physicians at present in Japan: 1. Graduates of the universities, 1514, with the title of Igakushi. 2. Graduates of the higher schools, 2329, with the title of Tokugyoshi. 3. Graduates of Saisei and Charity Hospital Medical Schools, 10,779, with the title of Eishi. 4. Those qualified in foreign medical schools, 94. 5. Practitioners before the present regulations went into force, and who received license without examination, 21,940. The first four classes are physicians who were educated under modern systems; the rest are Chinese physicians, including bonesetters, shampooers, administerers of acupuncture, etc. Therefore, in Japan, as he says, many physicians are really ignorant of modern medicine, and better medical education in Japan is demanded.

41. See abstract in Journal, xxxvi, p. 1491.

46. **Veratrum Viride.**—This article is given up to the replies that have been received by the editor of the *Therapeutic Gazette* from various prominent obstetricians as to the value of veratrum viride in puerperal eclampsia. J. Clifton Edgar believes it invaluable in cases where we have to use temporizing means until we can secure dilatation of the cervix. It is second in efficiency only to chloroform. It diminishes the pulse rate and convulsions are almost unknown when the pulse is 60 or under. He gives 10 to 20 minims of the fluid extract or one-half that quantity of Norwood's tincture subcutaneously, and repeats until the pulse continues below 60 to the minute, keeping the patient in the recumbent position. Richard C. Norris finds that the cases suitable for veratrum viride are those in which bleeding is often indicated. It can be employed sometimes when bleeding is not possible. A knowledge of the proper dose is essential. He nearly lost a patient from a hypodermic dose of 20 drops of the fluid extract. Smaller doses at frequent intervals are better, the interval being determined by the effect produced by the drug. Beginning with an initial dose of 8 minims he has repeated the administration in 5 minim doses as soon as the effect of the first dose did not appear in fifteen minutes or had begun to pass off. Barton C. Hirst has employed it for some twelve or fifteen years and has great confidence in its efficiency. It is most valuable in asthenic conditions; he would not use it in asthenia. Edward P. Davis expresses a similar opinion. Drs. George M. Boyd, W. Reynolds Wilson, Whitridge Williams, and Edward Reynolds have either had very little experience with it or consider it of slight value or even dangerous. Dr. Wilson thinks that it may possibly interfere with active uterine contractions which are Nature's means of removing exciting causes of convulsions.

47. **Gelatin in Hemorrhage.**—As a result of an analysis of the literature Sailer thinks the following conclusions are reasonable: 1. Gelatin increases the coagulability of the blood, whether applied locally, taken internally by the mouth, or injected subcutaneously or intravenously. 2. Applied locally it is usually harmless, and may, as Carnot suggested, aid in healing by improving the nutrition of the cells, although he regards this as doubtful. It may be injurious by promoting bacterial growth, and should probably always have some antiseptic added to it. 3. Injected subcutaneously or intravenously it is entirely harmless, and when the technique is perfect, practically painless. The solution should be thoroughly sterile; the dose employed should vary from one to three

grams of pure gelatin. 4. When administered by the mouth from 1 to 300 grams or perhaps more, should be employed daily. 5. It is of advantage in any form of local hemorrhage, such as epistaxis, hemorrhoids, or injuries. 6. It checks certain forms of internal hemorrhages such as hemoptysis, hematemesis, metrorrhagia, melena neonatorum. 7. It appears to be the best remedy at our command in the treatment of hemophilia, and to be of great advantage for purpura hemorrhagica, and in hemorrhagic forms of infectious disease. 8. At present it appears to be contra-indicated in only one condition, viz., acute nephritis.

48. **Pilocarpin in Eye Disorders.**—Hansell finds the effect of pilocarpin is of value in certain cases of inflammation of different structures of the eye. His method is as follows: A convenient hour is chosen, usually 3 p. m., and the patient is put in a hot bath ranging from 106 to 110 F.; during the bath he drinks a cup of tea. After twenty minutes immersion he is put into bed and receives a hypodermic injection of 1/12 to 1/8 of a grain of pilocarpin muriate. The sweating begins in a few minutes and is encouraged by hot bottles and blankets for two hours or more. If it should become slight or insignificant during the two hours, a glass of ice water is given, when the glands take on renewed activity. After the sweating, the wet blankets are removed, clean bed clothing substituted and the patient is allowed to remain quietly in bed until the next morning, when he may get up and dress until time for the next bath. If exhaustion follows the bath, a hypodermic injection of strychnin is given one-half hour before the next bath. The diet should be largely fluid and whatever local eye treatment is called for, is of course, administered and is not interfered with by the sweats. He refers to a number of cases in his practice and suggests that his own experience and that of some others who have tried it. has been so favorable that he feels he can recommend it in all chronic deep-seated inflammations of the eye that are not amenable to the usual remedies.

50.—See abstract in The Journal, xxxvi, p. 1725.

53. **Cystitis, Pyelitis and Pyelonephritis in Women.**—From a study of the results obtained in his investigation, Brown concludes: 1. The direct cause of the infection of the urinary tract in women is the invasion and multiplication of some form of micro-organism. 2. The commonest cause of these infections is the B. coli communis, which a consideration of the cases of acute cystitis definitely proves can and does in a large number of cases set up a true infection without the aid of any other micro-organism. 3. Marked variations are seen in the virulence of this micro-organism and in its pyogenic properties. 4. Other micro-organisms frequently found are the tubercle bacillus, various staphylococci and the B. proteus vulgaris; while numerous varieties of micro-organisms have been less frequently and occasionally met with, as the B. pyocaneus and typhoid bacillus. 5. The proportion of cases of infection due to the B. coli communis is greater in women than in men, probably due to the close proximity of the female urethra to the anus. 6. Besides the entrance of the micro-organisms, other factors are in most cases essential to the development of a cystitis; chief among these factors are anemia, malnutrition, trauma and pressure upon the bladder, congestion of the bladder and retention of urine. 7. In cystitis the chief mode of infection is by the urethra, although one must also consider as possibilities a descending ureteral infection from an infected kidney, pyogenic metastasis by means of the blood and lymph currents, and direct transmission of the micro-organisms from the intestinal tract, or from some adjacent focus of infection. 8. In pyelitis and pyelonephritis the usual modes of infection are along the ureter from an infected bladder, and by means of the blood and lymph currents; in the author's cases these modes of infection were found about equally represented. 9. In the great majority of cases of cystitis, both acute and chronic, and in the majority of cases of pyelitis and pyelonephritis, the urine is acid. 10. In the cases in which the urine is ammoniacal, the infection can be produced without the aid of any of the accessory etiological factors mentioned above, the irritation of the ammoniacal urine apparently being sufficient to render the bladder susceptible to infection. 11. In the case of infection of the kidney due to urea-decomposing micro-organisms, a stone is very likely to be present if the case is at all chronic. 12. Certain conditions exist which present most of the symptoms of cystitis but no infection; the most difficult of which to diagnose is probably urinary hyperacidity of neuropathic origin, the successful treatment of which depends upon the successful recognition both of its urinary features and its general basis. 13. Although the diagnosis of renal infections can be made with absolute certainty only by ureteral catheterization, a probable differentiation between renal and vesical infections can be made by a careful study of the urine alone. 14. Tuberculous infections of the urinary tract frequently occur with no other demonstrable tuberculous lesions elsewhere in the body. Probably a tuberculous gland would be demonstrable postmortem in most of these cases. 15. The colon bacillus seems to be the commonest cause of pyelitis, while the B. proteus vulgaris and members of the staphylococcus group are also found less frequently. 16. And finally, to be able to thoroughly understand the cases of cystitis, pyelitis and pyelonephritis brought to our notice, to make the proper diagnosis, to inaugurate and carry out a rational line of treatment and to give a correct prognosis, a careful chemical and bacteriological study of the urine is absolutely essential." See also 24.

54. **Strongyloides Intestinalis.**—Strong reports cases of dysentery with ulcer of the large intestine and abscess of the liver and retroperitoneal abscess in which there was an intestinal infection of the strongyloides intestinalis. The kidneys were degenerated and the liver, also the heart muscle. A thorough postmortem examination was made, and a description of the parasite is given with a historical review of the literature in the pathology. From a study of the microscopical sections of two fatal cases and from observations made upon five clinical cases he cannot consider the parasite harmless, nor does he regard it as a direct danger to man. He believes that it can produce an intermittent diarrhea with intestinal disturbances, and anatomically, a catarrh of the small intestine. The parasite certainly causes some injury from its rapid mechanical movement, but whether it produces any chemical substance harmful to man has yet to be proven. Moderately severe infections probably cause only slight injuries. The milder cases of infection generally yield to large doses of thymol, with general tonic treatment. It may be necessary to repeat the treatment at intervals. In very severe infections neither male fern nor thymol are of any apparent value in curing the disease and ridding the patient of the parasite.

61.—This article has appeared elsewhere. See The Journal of August 10, title 60, p. 406.

70. **Malignant Neoplasms.**—Currier favors the non-surgical treatment of cancer, pointing out that many cases treated by quacks recover. He has watched them for years. He resolved to know the value of these methods so he has been studying general and local medication. For the general medication to assist nature in her endeavor to relieve herself, he believes in the free use of phosphates, protonuclein, thyroid extract, the iodids to stimulate glandular activity, which in many cases is the most important thing to do, Chian turpentine, which he thinks has good results when properly administered, phytolacca, sulphur, echinacea, and conium. For local treatment he believes that electricity will be an agent of great value, though it has failed in private practice. Cataphoresis is opening up a field of vast possibilities. Arsenious acid, which has been much used, is an excellent thing, though quite painful unless prepared with some local anesthetic, such as cocain or eucain B. Chromium chlorid should be used in cases of scirrhus situated deep in the cellular tissue with the skin intact. It has the same selective action as arsenious acid when the strength is properly regulated and its action can be guided in any direction. It is best to commence by removing the cuticle over the most prominent part, and he says one who has never tried it would be surprised to see how quickly the tumor contracts and how smoothly it separates

from the parts around. Salicylic acid with lactic acid makes a desirable application for disease on the accessible mucous surfaces other than the mouth. It must be applied freshly prepared each day. If persevered in it will cause the diseased mass to separate in from five to ten days. He reports good results with formalin. As soon as the line of separation commences it should be filled in once or twice a day with protonuclein special. Eucain B. or cocain is the best local anesthetic where there is pain. The general edema being so great that no tumor can be discovered, he uses resorcin and phytolacca ointment which soon outlines the growth. He reports three cases, one of epithelioma, the second and third of cancer of the breast, and the second with enlarged axillary glands, in all of which there was good recovery.

83. **Puerperal Eclampsia.**—The remedy here recommended for puerperal eclampsia is veratrum viride with which Gordon has treated four cases, all of which recovered. In no case was there a convulsion where the pulse was held below 60. In the most recent case there were six convulsions before veratrum viride was used, under the administration of chloral, chloroform and morphin, while 10 minims of fluid extract of veratrum hypodermically brought the pulse down to 50, made it soft, and convulsions ceased. The uterus was emptied in all of these cases out of regard for the general opinion of the profession, and not from a lack of confidence in the medication. He holds that there is ground for some conservatism in this matter when we consider the twenty-six successful cases thus treated by Dr. Newton without interference with pregnancy. He thinks 10 minims the proper initial dose, with 5 minim doses at intervals of one-half hour until the pulse comes down to 60 or below. It is not often necessary to give a second dose, as the first is generally efficient.

84. **Retroflexions.**—Gellhorn recommends a method of vesico-fixation invented by Mackenrodt in 1895 for retroflexion of the mobile uterus and describes the operation. For the details of this the reader is referred to the article. A number of cases are reported. The advantages claimed are the restoration of the physiological situs in the pelvis as much as possible. The peritoneum being shortened by loosening up the bladder and sewed high up to the fundus on a line between the tubes, and a serous connection between uterus and bladder being thus established. The second part of the operation consists in sewing the vesico-vaginal septum to the anterior surface of the womb, thereby the bare posterior wall of the bladder becomes attached to the anterior wall of the uterus, which is covered with peritoneum, thus forming a sero-fibrous connection, sufficiently strong to hold both organs in place, but not so rigid and unyielding as to interfere with the development of the womb in case of a later pregnancy.

86. **Cystocele.**—In Sutton's operation "the incision is made around the cervix extending to the lateral sulci, forming the base of a triangle the apex of which is at the meatus, the sides of which take in sufficient of the anterior wall when edges reunited will completely retain the superimposed bladder; denudation made as one flap. Amputation of the cervix, or repair of the cervix, as the case may require, being performed at the time of the first incision, and dissection of the tissues from the anterior surface of the cervix sufficiently to allow the easy repositing of the uterus. Sutures introduced in front of the cervix may be continuous catgut or interrupted silk as the surgeon desires. Buried sutures not necessary, wound closed; result is a lengthening of from two and a half cm. of the vaginal wall with repositing of the cervix into the hollow of the sacrum, where it properly belongs, out of the reach of the patient who usually informs me after the operation that she can no longer feel the womb. This operation, of course, being supplemented with repair of the posterior wall of the vagina and perineum. When performed in this manner suspension of the uterus or shortening of the round ligaments intra-abdominally can be dispensed with, as the organ assumes its natural position in consequence of the lengthening of the anterior vaginal wall." He has performed this operation a number of times, and the results are uniformly as stated.

87. **Electricity in Gynecology.**—Walling recommends the use of electricity by galvanization, faradization and static spark in amenorrhea, dysmenorrhea, ovarian neuralgia, delayed menstruation, erosions, metritis and endometritis, pyosalpinx, subinvolutions and fibroids.

88. **Gold-Beater's Skin Court-Plaster.**—Day recommends gold-beater's skin court-plaster as having the following advantages as a surgical dressing when prepared by the cumol process: "1. It is aseptic, antiseptic, and impervious to germ life. 2. It is thin and pliable. 3. It is transparent. 4. It is fibrous and adherent. 5. It forms a light and comfortable dressing. 6. It is readily removed by the application of moisture."

89. **The Dry Method in Surgery.**—Walker advocates the use of the dry method in surgery as meeting all the requirements and favoring infection less. He has performed by the dry method 262 operations on 234 patients with a mortality of 5. One of these fatal cases was a suppurating fibroid, and the patient had been septic for weeks, and it was done *in extremis;* another was a resection of the pylorus and one-third of the stomach for cancer; the third was a resection of the sigmoid flexure for malignant disease, and the fourth, an infected urachus. In the fifth, death occurred forty-eight hours after a prostatectomy. Of the total number 163 were clean cases, and in 2 there was a suppuration in the wound. The remainder were absolutely aseptic in healing. The infected cases were 71 in number, of these there was no suppuration afterward in 47; 24 were septic after the operation. Some were emergency cases and the preparation not as good as it should have been. Of the total number 72 were laparotomies.

96. **The Brain and Its Evolution.**—The special point in Woodruff's article is that civilization and brain development have gone hand in hand, and that the lower races that have not taken part in it are forever unfitted for the former, the more so the earlier "they escaped from the factory of brain." He holds that the negro is unsuited for civilization, and must necessarily become extinct; that change of climate must necessarily be accompanied by change of type; that religion is purely a matter of brain evolution and race; that evolution is still a constant effective factor, and that efforts to modify it by checking or preventing degeneration are futile. We are now passing through the critical period, separating the earlier era of savagery and the future one of specialists.

99. **Dispensary Treatment of Mental Diseases.**—Channing gives an account of the methods of treating out-patient cases of mental disorder in the Boston dispensary. Many of them were developed cases of insanity, unrecognized or otherwise. Others were incipient cases in which the attack was checked by the treatment received, or cases that were prevented from developing into insanity. Still others were epileptics, cases of simple depression, or were defective children, susceptible of amendment under proper treatment. Some cases were benefited by being sent to the hospital in time, others they were able to prevent from going there. The clinical advantages are also discussed.

100. **Dementia Precox.**—Browning's article is a translation from the German of Kraepelin.

101. **Chloretone.**—Nine cases of the continued use of chloretone are reported by Dunton; in all but one unfavorable action on the heart, kidneys, etc., was observed. He thinks the main disadvantageous action is on the heart and that it is depressant in character. The total amounts given in each case ranged from 200 or 300 to 1100 grains. The latter amount was reached only in the patient who showed no bad effects.

102.—This article was noticed in The Journal in the issue of July 20, page 218.

Treatment of Wounded in Naval Actions. Fleet-Surgeon Gilbert Kirker, M.D.—The author discusses the subject under these heads: 1, the surgeons' station; 2, the time of treatment; 3, the conveyance of the wounded. As regards the first, modern ships of war have not the old cockpit; Kirker thinks an operating room should be provided, protected in time of action, so that the experience of the Japanese ship *Hujei*, where all medical supplies were destroyed and the whole medical force was put hors de combat by a shell, should not be repeated. As regards time of treatment it seems to be generally held now that any elaborate surgical work during action is impracticable; but naval actions are liable to be quickly over. The men should receive instruction as to first aid, and stimulant and restorative drinks be provided. For the conveyance of the wounded, a ship ambulance should meet several indications; it must retain its occupants safely in all positions; it must be able to slide down steep ladders, at any angle, be short enough to go around corners, in confined spaces, and where two men can not move it well in confined spaces it should be transportable by one. He mentions certain appliances, among them one of his own device, an "ambulance sleigh," which is now under trial.

The Disposal of the Wounded in Naval Actions. SURGEON F. H. A. CLAYTON, R. N.—This article reviews the conditions rather more in detail than does Kirker, pointing out the necessity of safe storage of the principal medical supplies, having dressing stations only on deck with first aid appliances, mattresses, etc. On ships where a protected operating room is unavailable several localities may be selected, in case any one is liable to be wrecked, and utilized at the earliest opportunity. Sterilized clothing for the men to be put on before action is suggested, and the desirability of a good and always ready application for burns. The picric acid treatment suggests itself from its simplicity and the infrequency of needed changes of dressing. The importance of ambulance drill and instruction is dwelt upon.

Floating Hospitals. INSPECTOR-GENERAL BELGRAVE NINNIS, R. N. (retired).—The points emphasized as of supreme importance by the author are the following: 1. That the ship should be of metal, cased on the outside with wood, thus combining the cleanliness of metal with the coolness and nonconductibility of wood, and that there should be no possibility of communication between the bilge and the wards. 2. That the wards should be absolutely without communication one with the other, and that each should have direct and independent air communication with the upper deck. 3. That the portion of the main and middle decks appropriated to the waterclosets should extend across the deck, so that a through current of air could be secured. 4. That the watercloset when in use should be absolutely cut off from this space. 5. That the platforms fitted outside the main and middle decks be of such a size as to accommodate a stretcher or lounge, and the parts leading on to them be in such a position as to give easy passage to a stretcher or carrying chair. It is most essential that in these ships lighting should be by electricity, as the power required for producing this would be utilized for various other purposes, as is done in our larger passenger steamers.

Healthfulness of Modern Warships. STAFF-SURGEON W. E. HOWE, R. N.—Howe shows from official tables that the earlier ironclads were healthier than the old wooden ships, and that the more modern vessels are better still than these. The requisites for a healthy ship are given by him as follows: "1. Have certainly not less than 120 cubic feet of space for each man, and more in the tropics. 2. Have uptake ventilators from every compartment, opening as near the top as possible. These should be so constructed as to be capable of being cleaned by a brush pulled through. 3. Cowls and air-shafts are needed to be supplemented in all favorable weather by a windsail for each hatchway and wind scoops for each port or scuttle in the side. Artificial ventilation is required for every space in which men live (only to be used on the main deck in bad weather). 4. She should be warmed and kept dry by steam radiators. In 1888, the *Alexandra* having been fitted with electric light and being now kept drier by the heat radiated from the boiler always alight, had less than half as many cases of Malta fever as she had had in each of the four preceding years. 5. Whenever decks are washed, the last washing over should be done with a 1 in 1000 solution of perchlorid of mercury or another antiseptic. The mess tables and stools are similarly washed. This reduces the liability of casual wounds to inflame. I would like also to spray the beams overhead witth formalin solution once a week in order to diminish the occurrence of sore throats and other septic diseases. But I quite believe the best general antiseptic on board a ship to be fresh dry air in plenty. 6. There should be a drying room for the wet clothes and bedding of the ship's company."

The Theory of Air-Borne Typhoid in Armies. H. E. LEIGH CANNEY, M.D.—From a consideration of the conditions under which typhoid originates and spreads in armies in India, South Africa, and Egypt, which he reviews in detail, including those of the camps of workmen at the Assouan dam, Canney concludes: 1. That the evidence of air-borne typhoid recorded in Indian military experience is not established. 2. That in South Africa and Egypt the evidence is opposed to this theory. 3. That in India, South Africa, and Egypt the immense weight of evidence and probability is in favor of a water-borne origin and spread. 4. That the evidence from Egypt proves that if the avenues to man by means of water be protected, all other avenues are powerless to originate and spread typhoid in large bodies of men. There is strong evidence to suppose that the same methods would bring about like results in India, South Africa, and other countries. 5. That the origin and spread of typhoid by means of flies and dust being theory only, can only be discussed as such in relation to certain laboratory experiments, and that in practice it is unjustifiable to hold this theory, if it should deter, delay or hinder the adoption in armies of the most vigorous, and comprehensive measures against water-borne typhoid. The laboratory research, he holds, proves: 1. That in soils in which it might be expected it is never found. 2. That it is extremely difficult for the typhoid bacillus to live in soil, and that, if much moisture exists and a temperature above 66, it will only live some hours. 3. That the action of light and total drying on the superficial layers of infected dust are so specially deadly to the typhoid bacillus as to account for the fact that, though it may be partly dried in the laboratory, it has not been driven through the air and recovered. 4. That its recovery from water is difficult, and failure to recover it does not show either that it was not there at the time of examination, or at any previous time. It is interesting to find that the conclusion arrived at in the study of the natural experiments or epidemics coincides closely with the facts which laboratory research has established. Enteric fever will have to be met in all parts of the world on the water-borne theory mainly, though every other avenue must be guarded. His conclusions were combated in the discussion following by Lieut.-Col. Giles, I. M. S., who criticised his deductions from India where air-borne and fly-borne typhoid was a frequent mode of infection and the water-borne theory failed to account for many attacks.

The Lancet, August 24.

How Can the Tuberculin Test be Utilized for the Stamping Out of Bovine Tuberculosis?—SHERIDAN DELEPINE, M. D.—Delepine finds from his investigations that: 1. Tuberculin is an almost infallible test of the presence of tuberculosis in animals under seven years of age when this fluid is used with proper care. In older cattle clinical methods are more reliable than the tuberculin test as used at present. (The use of larger doses than the usual ones may, however, be resorted to with advantage in these cases.) 2. It is possible by the use of tuberculin and thorough disinfection of cattle-sheds to stamp out tuberculosis from a herd in the course of one year. 3. Cases of infection which may accidentally occur after this preliminary removal of tuberculous cattle can be easily and economically detected by periodical use of tuberculin. 4. Tuberculous animals between two and three years of age can be disposed of on the meat market without serious loss. 5. The slaughter of cows in calf or of milch cows not in an advanced stage of tuberculosis involves a serious loss to the farmer, and so long as tuberculosis is as prevalent as it is at the present time it is doubtful whether the measures necessary for the extirpation of tuberculosis can be left to private efforts without state help. 6. To remove the chief sources of infection immediate slaughter should be resorted to in the case of all animals in a state of advanced tuberculosis, and of all cows with tuberculosis of the udder. 7. Milch cows and cows in calf in which tuberculosis is not very advanced should be isolated and slaughtered only after they have been suitably prepared for the butcher. The milk of tuberculous cows should invariably be sterilized by boiling. 8. Valuable breeding animals free from advanced tuberculosis or tuberculosis of the generative organs should be isolated; and they can be kept for a time for breeding purposes, provided the calves are isolated and fed on sterilized milk. 9. Measures which do not provide for the removal of all tuberculous animals from a district, for the disinfection of all cattle-sheds in that district, for the periodical testing of all the animals within the district, and which do not give the means of preventing the importation of tuberculous animals can not be expected to yield satisfactory results. On the basis of these conclusions he advises dividing the country into administrative and inspection districts; marking and registration of all cattle and isolation of tuberculous animals, and disinfection of sheds where they have been; immediate slaughter of all advanced cases, and fattening for the market of those less advanced, the slaughter to be done in public abattoirs to insure proper meat inspection. He would have compensation for condemned animals allowed for a year or two; after that, the finding of an advanced case to subject the owner to a penalty. He advises the testing of all introduced cattle to prevent fresh sources of disease; no cattle over six years old should be imported. All milk from tuberculous cattle should be boiled before used, and control of imported foreign dairy produce to insure equal standard of purity as with home produce. In order to prevent disturbance in the dairy business he would enforce these rules gradually, first in one, then in another part of the country, taking five or six years to make them complete and uniform.

The Treatment of Melancholia. L. C. Bruce and H. de Maine Alexander.—The authors say: "We believe melancholia to be a disease of disordered metabolism and that treatment should be directed towards increasing the excretion of waste products of this metabolism through the channels of the urinary and integumentary systems, and we mechanically accomplish this end by administering to our patients an abundant fluid dietary. By means of this treatment the blood gets rid of its overcharge of waste products and the arterial tension falls. We assist digestion by giving milk frequently, and in small quantities, as it is the most easily assimilated food. We consider the forcing of solid food (or such as custards) upon a patient suffering from acute melancholia just as injudicious treatment as would be the feeding of a patient suffering from typhoid fever exclusively on beef-steaks." They give charts illustrating the progress of the treatment in four cases; also a weight table of the last eight cases treated. They believe that thus managed, melancholia is a disease very amenable to treatment.

The Conditions of the Blood in Scarlet Fever. F. Percival Mackie.—From the examination of the blood in twenty-five cases of scarlet fever of varying degrees of severity, and at various stages of the disease, Mackie found that moderate anemia was a constant feature. In half the cases the red cells numbered between 3,500,000 and 4,000,000 per cubic millimeter; the highest count was 4,170,000. The percentage of hemoglobin was in direct ratio to the number of red cells, so that the individual corpuscular richness kept him very nearly normal. All the cases were accompanied by leucocytosis to a pathological degree, that is, over 10,000 per cubic millimeter. This leucocytosis seems to bear no direct ratio to the temperature, but varies rather with the severity of the throat lesion, and to a less extent with that of the rash. In most cases the increase of leucocytosis began about 24 hours after the appearance of the rash, and reached a maximum after the subsidence of the general symptoms, and at times varying in different cases from the third to the tenth day. Mild cases show a maximum increase about the fourth day after the appearance of the rash, and therefore generally not less than 24 hours after the complete disappearance of the rash. In the presence of septic complications the duration and intensity of leucocytosis naturally depends upon the intensity and duration of such complications. In anginal cases the leucocytosis may be very high (93,300 in one case), and in the one fatal case it diminished as the disease became more severe. This seems analogous with the blood condition in pneumonia, where a decrease of leucocytes in a severe case is looked upon as a bad sign. Percentage enumeration of white corpuscles was only carried out in a few instances, but in these the chief increase of eosinophile cells was present (5 or 6 per cent.). These results agree in the main, as he shows, with those of other observers. They also tend to bring the question of leucocytosis in scarlet fever into line with that found in other diseases, notably pneumonia, and indicate that this leucocytosis is a favorable sign, perhaps having some relation to acquired immunity. Its absence, on the other hand, especially in a severe case, is of bad import, and the same is true of a sudden drop in a case of increasing severity. It is of further value in his experience as indicating septic complications such as deep suppuration in the neck or obscure middle ear disease not revealed by the temperature. The condition of the throat has much to do with the leucocytosis which is not excessive when the discharge is free. Contrary to Cabot's experience, Mackie found no leucocytosis until the rash had appeared for twenty-four hours. He remarks that the increase of eosinophile cells is interesting and supports the theory of their having to do with the production of antitoxin, though unfortunately it does not hold good in other diseases where antitoxin is produced. He is inclined to think that these cells are in some relation to skin conditions, as they are increased in many skin diseases. He has not, however, been able to determine any relations between them and the scarlet fever rash or between the leucocytosis and the kidney complications. The deficiency of red blood cells indicates rational use of iron medication, except possibly in cases with arthritic complications.

Annales de l'Institut Pasteur (Paris), July.

Importance of the Micellae in the Chemistry of the Cell. S. Posternak.—Posternak describes a series of comprehensive researches on the structure and changes in colloid substances. He has become convinced that the different groups can be differentiated by the elective character of the adhesive affinity of their micellæ. The adhesive affinities of the micellæ are distinctly elective and specific, like chemical affinities. As protoplasm is made up principally of colloid matter—whose micellæ do not become dissociated without the intervention of a chemical reaction—the most important factor in the structure of the cell may prove to be the elective affinities of the micellæ. The chemistry of the cell is something more than merely molecular; it is evidently to a large extent, micellar.

Annales des Maladies des Org. Gen.-Urin. (Paris), June.

Indications for Nephrectomy in Renal Tuberculosis. F. Legueu.—Patients are frequently treated for tuberculosis of the bladder when the real trouble is incipient renal disease. Nephrectomy is indicated when the tubercular lesions are progressing and causing emaciation. Hemorrhage and pain are secondary indications. Emaciation progressing in spite of medicinal measures clearly indicates nephrectomy. Tubercular infection of the bladder or lungs is not an obstacle to nephrectomy. It is frequently remarkably benefited by it. The ureter must be resected also, if very much affected. The upper end alone may be removed, leaving the rest to atrophy. When the kidney is removed before the appearance of other manifestations of tuberculosis, permanent cure may result. One patient with tuberculosis of the lung, kidney, one ureter and bladder, gained fifteen pounds after the infected kidney was removed.

July.

Pathology of the Seminal Vesicles. R. Duhot.—Acute and chronic inflammation of the seminal vesicles is much more frequent than generally supposed, Duhot asserts as the results of extensive clinical and experimental research. Gonorrhea is not the sole cause—any of the pyogenic microbes may induce it. Chronic spermatocystitis is especially frequent. It may be consecutive to chronic gonorrhea or merely the consequence of repeated inflammations in the neighboring organs. The changes induced in the vesicles by inflammation are both numerous and severe, interfering with the functions of the organ and inducing sterility by altering the composition of the sperm and killing the spermatozoids. The changes from amyloid degeneration and acute diphtheritic inflammation of the seminal vesicles in two cases are illustrated.

Treatment of Contusion of the Kidney. P. DELBET.—The 320 cases collected from the literature include Fenger's, published in THE JOURNAL in 1889. Delbet's conclusions from this review, from one personal case and considerable experimental research, are that the treatment of renal contusion is of necessity purely symptomatic. Immediate intervention is indicated on suspicion of intraperitoneal hemorrhage. Hematuria alone does not justify it. Secondary operation is indicated only in case of symptoms and gradually increasing subperitoneal hemorrhage, anuria or persisting hematuria. Intervention, however, is formally indicated in case of secondary hematuria. The operation should be as conservative as possible, unless the kidney has been torn from its pedicle, or is crushed completely or has the "dead leaf" color; any of these conditions demand nephrectomy. Otherwise the kidney should be merely exposed, tamponed and the wound left open. In the personal case described a young man had fallen from a second story. The kidneys showed no signs of injury at first, but suddenly hematuria and a swelling in the region developed, apparently cured by nephrotomy and suture. Five months later, however, the symptoms recurred, and notwithstanding attempted nephrectomy, death occurred in a few hours.

Technique of Suturing the Urethra. J. ZADOK.—The healing of an incision or wound in the urethra is much facilitated by the technique which Zadok has practiced on fifteen patients with brilliant success. The urethra alone is sutured. The wound in the soft parts is merely extensively drained through the gaping lips. This technique is indicated in all cases in which the urine is septic or there is suppuration of the meatus or perineum at any point. The permanent sound should be changed on the third day, and removed on the fifth to eighth day at latest, and progressive dilatation commenced.

Presse Medicale (Paris), August 7.

Transmission of the Meningococcus by the Respiratory Passages. BUSQUET.—Nasal mucus from patients with epidemic cerebrospinal meningitis was placed in the nose of guinea-pigs. All the inoculated animals became infected and the meningococcus was cultivated from the cerebrospinal fluid of those that died. Other animals inoculated with nasal mucus from the infected animals also died. Nasal mucus from the infected animals was placed in the nose of other animals of the same species, and the latter likewise succumbed to the infection. Cerebrospinal fluid from patients dying from the disease was placed on the nasal mucosa of animals with like positive results.

August 14.

Forceps for Simultaneous Hemostasis and Suturing. J. C. LIMA CASTRO.—The upper surface of the forceps is cut in a series of deep, parallel, transverse grooves. The side view of the blades of the instrument resembles an arc of a cogwheel. The forceps are applied for hemostasis as usual, and the stitches of the suture are taken through the tissues squeezed flat between the blades, one stitch at the bottom of each groove in turn. The forceps was designed especially for use in hemorrhoids, but has proved valuable in many other operations.

Revue de Chirurgie (Paris), August.

Radiography in Surgery of the Lungs. T. TUFFIER.—Operations on the lungs in which the lesion was accurately diagnosed beforehand were successful in 71 per cent., that is, the mortality was only 29 per cent., while the mortality was 60 per cent. in the cases in which there was a mistake in the diagnosis. In 300 cases which Tuffier has collected, the lesion had been incorrectly diagnosed in 48. In 9 cases the lesion was supposed to be in the lung when it was in reality in the pleura, liver or kidney. Tuffier's personal experience now includes 25 operations on the lungs. He was able to apply radiography in 8. In 5 the results were extremely satisfactory; in 3 they were negative. He urgently advises radiography and especially stereo-radiography, in all cases before operating on the lung. When the radiographic findings contradict those obtained by percussion and auscultation, the latter should be neglected and the radiographic indications followed. The *x*-rays, however, are liable to fail in case of living hydatids, and they are unable to afford information in regard to the multiplicity of the foci. The results are liable to be negative when the lesion is on the left side, as the shadow of the heart may cover it. In two cases gangrenous abscesses in the lower lobe of the right lung cast distinct shadows, enabling them to be promptly evacuated with rapid recovery of the patients. In another case the entire left lung was opaque, but the shadow was a trifle denser in the lower third, where the dulness was most marked, where the focus was found. In a fourth case, radiography located the lesion toward the base of the lung while the stethoscope indicated a higher site. The incision was made at the latter point, with negative results even after resection of the rib. The rib below was then resected, and the pleura was found adherent with the lung sclerosed and hard, and a series of pockets in the bronchi were discovered at the points indicated by the *x*-rays. In the three negative cases, the lesion was on the left side.

Laceration of the Vessels in Fractures of the Clavicle. E. GALLOIS.—Laceration of the vessels is a very serious complication of simple fracture of the clavicle. Only 2 patients recovered in the 11 cases collected. The successes recently obtained in operation on the vessels of the neck, justify the assumption that improved technique will reduce the mortality of these injuries of the vessels from fragments of the fractured clavicle. Free incision must be made and the entire clavicle resected if necessary. Wounds of the veins seem generally less serious than those of arteries. Gallois' experiments on the cadaver and clinical experience have shown that the subclavian vein is always injured at the point back of the inner third of the clavicle, and the internal jugular, several centimeters above the sterno-clavicular articulation. Compression or ligature has great possibility of success under these circumstances. There is no danger connected with the interruption of the circulation of the large veins at the base of the neck. A diffuse aneurysmal hematoma from the subclavian is more serious. All the patients have died, irrespective of the method of treatment adopted. In a personal case reported, the indirect fracture of the right clavicle was followed by an arteriovenous aneurysm. An injection of gelatinized serum was made, but the results were deplorable. Suppuration at the point of injection followed, with consequent inflammation of the aneurysmal sac, requiring operation to forestall pyohemia from perforation of an abscess into the large vessels. The wall of the sac had become weakened by the suppuration, and ruptured. Gelatin treatment should be reserved for internal aneurysms in which surgical interference is impossible. It should be absolutely rejected in all cases amenable to operation. In the case of the aneurysm mentioned above the inner fragment of the clavicle was removed and the incision carried along the entire margin of the sterno-cleido-mastoid muscle.

Anuria in the Course of Carcinoma of the Uterus. PATEL.—Anuria may appear as the first symptom of malignant disease in the uterus, or it may appear suddenly in the course of recognized carcinoma, or may develop progressively. The latter most frequently occurs. Nephrostomy by the lumbar route is the operation of choice, except in advanced stages of malignant disease. If the general condition is good, the operation should be performed promptly, to forestall or cure the resulting uremia. In two ureterostomies and six nephrostomies that have been reported in France, the patients survived several months after the latter operation, but death followed in a few days after the operations on the ureters.

Traumatic Rupture of the Spleen.—Two cases of rupture of the spleen from the kick of a horse were related at a recent meeting of the Société de Chirurgie. There were no signs of internal hemorrhage until twenty-four hours afterward, when splenectomy was performed. Only one patient recovered. The other succumbed to septicemia the sixth day. The only signs of the injury at first were pallor, vomiting once, and rigidity of the contracted abdominal wall.

Semaine Medicale (Paris), August 14.

Clinical Utilization of the Dosage of Iron in the Blood. L. Bard.—According to Bard's belief, all the tissues of the organism are constituted on a common plan, and comprise a fundamental species of cell, which ensures their special existence, but has nothing to do with their physiologic activity, and, on the other hand, one or more derived substances, formed by the cells in their protoplasma or outside, which are the only substances endowed with the physiologic function. In the blood, for instance, the fundamental cell is represented by the leucocytes, while the hemoglobin and the serum are the derived substances. According to this theory, the hemoglobin is not a stable substance, with the definite composition usually attributed to it. It varies according as it is freshly formed or ripened, and these variations cause the relations between the hemoglobin and the color of the blood to be modified under diverse circumstances. For example, the iron is increased in proportion to the color, that is, the amount of iron is increased more than the color has changed, in comparison with normal blood, in all cases of simple anemia with normal blood-producing and blood-regenerating powers. On the contrary, the amount of iron is less, in proportion to the color, in all cases in which the regeneration of the blood is defective from cachexia or serious organic disease. In certain affections the diagnosis is uncertain owing to the impossibility of determining whether the accidents observed in chlorosis, for instance, are due to the intensity of the latter, or whether the chlorosis itself is caused or maintained by some organic affection of heart or lungs. Dosage of the iron will promptly decide the question. In simple chlorosis, before it is improved by treatment, the proportion of iron surpasses the color by 10 to 20 per cent. on an average. When the chlorosis is complicated by tuberculosis, the inverse proportion prevails and the iron is 10 per cent. behind the color. The same phenomenon is noted in anemia symptomatic of tuberculosis, with or without chlorosis. This comparative dosage of the iron may also serve to solve some of the problems of the effect of altitude on the blood.

Berliner Klin. Wochenschrift, July 29.

Chronic Pentosuria. F. Meyer.—A patient was treated at Leyden's clinic for chronic pentosuria. The symptoms were extreme emaciation and neurasthenia with rebellious neuralgia. The tolerance for carbohydrates and food rich in nuclein was remarkable. The patient rapidly improved on a mixed diet.

August 12.

Subcutaneous Injections of Gelatin for Hemostasis. Grunow.—Twenty-seven cases of severe internal hemorrhage were treated at Quincke's clinic by the subcutaneous injection of gelatin, with only one death. In 7 cases the hemorrhage was from the lungs, including one of gangrene consecutive to injury from swallowing lye. Five days after the first injection, a quantity of clots was expectorated, with 380 c.c. of blood. Four days later another mass of clots was expelled with less blood. The largest clot was the size of the finger, with distinct ramifications. In fifteen days the sputum was quite free from blood. The patient died a week or so later from the consequences of an abscess, not from hemorrhage. In 8 cases the hemorrhage was in the intestines; 6 in the course of typhoid, 1 in leukemia and 1 in purpura hemorrhagica. In 7 the hemorrhage was from the stomach; from ulcer in 5, carcinoma in 1 and hemophilia in 1. Twice the hemorrhage was from the bladder, twice from the kidney and once from an aneurysm. In the overwhelming majority of cases the hemorrhage was arrested, transiently or permanently. The failures were probably due to inadequate dosage. As the hemostatic influence of the gelatin is transient, it is administered daily as long as necessary, injecting 2 gm. of gelatin in each thigh, dissolved in 100 gm. of salt solution, using a bulb instead of a syringe, with the air filtered through cotton. The apparatus is kept always ready for immediate use. Other hemostatics were applied at the same time, but the recurrence of the hemorrhage when the amount of gelatin was reduced, and the expulsion of large, tough coagula, indicate that the gelatin was principally responsible for the hemostasis. The gelatin is useless unless a sufficient quantity is injected, and repeated as long as the tendency to hemorrhage persists, and for a few days afterward. There are no contra-indications. The temperature commences to rise a few hours after the injection in nearly every instance, sometimes accompanied by a chill, and may reach 102 or 103, or even to 104 F., but is lower at each succeeding injection. In one case a 3 per cent. solution was used, and three tumors developed under cool skin, quite tender, but subsiding in a couple of days. Urticaria was observed several times in one case. These by-effects are disturbing to nervous patients, but their inconveniences are not sufficient to prohibit the use of the gelatin in case of severe internal hemorrhages. The degree of pain of the injection is proportional to the tension of the tissues. The gelatin is absorbed in a few minutes to twenty-four hours or longer. Absorption is more rapid in lean patients with loose subcutis and in patients who have lost much blood. The needle should be pointed in various directions to distribute the gelatin as much as possible. The urine was free from blood in eight days after commencing the injections in a case of acute hemorrhagic nephritis. In a case of aneurysm of the pulmonary artery, systematic injections were followed by the retrogression and final disappearance of all the symptoms of perforation, including a palpable, fluctuating tumor under the skin.

Centralblatt f. d. Grenzgebiete (Jena), August 10.

Surgical Treatment of Essential Epilepsy. A. Pilcz.—An array of 105 communications on the surgical treatment of essential epilepsy, is reviewed in this article, including Beck's and Laplace's articles in The Journal in 1897 and 1899. Pilcz concludes that on the whole we may safely assume that operation is useless. Neither sympathectomy nor craniotomy is capable of insuring a permanent cure nor even a lasting improvement. He personally considers these operations as more serious than usually accepted. Graf, for instance, reports a mortality of 6.1 per cent. from trephining. Three cases of death after sympathectomy have recently been reported, including two reported by Braun, out of nine in which he had operated without a single success.

Muenchener Med. Wochenschrift, August 20.

Stab Wounds of Diaphragm. C. Schlatter.—Frey collected 33 cases of stab wounds of the diaphragm, all fatal but 4, generally from incarceration of the protruding intestine. Schmidt, on the other hand, collected 43 cases in which operation resulted in the recovery of all but 6. When death occurred it was always in the first few hours. These figures indicate the necessity of operative treatment, and the danger of delay. They justify Postempski's recommendation of investigating the wound in the diaphragm with the disinfected forefinger, enlarging the external wound for the purpose if necessary. Schlatter reports 2 cases of stab wound in the lower portion of the thorax, with evidences of hemorrhage into the pleural cavity. The symptoms of marked anemia—scarcely to be attributed to a hemorrhage from the lungs on account of the limited area of dulness—and the vomiting, suggested injury of the diaphragm. The dyspnea and results of percussion and auscultation were not pathognomonic. In one of his cases, a rib had been cut by the blow and he surmised deep injury. He, therefore, resected the ninth rib and enlarged the wound found in the diaphragm from 3 to 8 cm. Blood poured out from the abdomen. The forefinger introduced through the diaphragm revealed an incision 2.5 cm. deep in the edge of the liver and another, shallower, lower down. The bleeding was checked by compression, when it was found that the kidney had also been incised to a depth of 8 cm. and more. The wounds in liver and kidney were disinfected with small gauze sponges, and the incision in the kidney was sutured with 5 stitches taken deep in the parenchyma. The larger incision in the liver was sutured with 4 stitches through the parenchyma and capsule, and the smaller, with a single stitch. The bleeding was immediately arrested. The abdominal cavity was then cleansed of the accumulated blood with gauze sponges, and the wounds in the diaphragm and pleura sutured with silk. The wound in the skin was then sutured without drainage and the patient rapidly recovered with no symptoms of any reaction on the part of the peritoneum or pleura. He left the hospital in thirty days and continued his mountain climbing without the slightest inconveniences. This patient was a printer, 24 years old. The second patient was 17, and the stab wound was in the seventh interspace, and extended into the pleural cavity. The eighth rib was resected and an incision 3 cm. in length discovered in the diaphragm. A sound introduced failed to demonstrate any opening in the peritoneum. A vessel in the wound in the diaphragm was bleeding profusely. This was ligated and the wound in the diaphragm closed by four silk stitches. After removal of the blood clots from the pleural cavity the wound was sutured, leaving a gauze drain. The cyanosis and dyspnea seemed somewhat intensified by the operation, but soon subsided. Slight temperature was observed the third day, but otherwise recovery was uneventful and rapid. The patient was dismissed in thirty-three days completely recovered. Schlatter observes that the immigration of Italian laborers may increase the frequency of such wounds, as almost all of the 89 cases of stab-wounds of the diaphragm on record were inflicted by Italians. In a case he published a few years ago, a portion of the omentum, the size of a fist, protruded from the wound in the pleura. He was able to reduce the hernia and suture the diaphragm with six silk stitches and patient recovered.

Thrombosis of Left Innominate Vein with Pericarditis. P. v. Zezschwitz.—A case is described of thrombosis of the left innominate vein from compression, the consequence of a pericardial exudate superposed on a pleuritic effusion. The latter alone had been diagnosed, and the unilateral hydrothorax of 5 liters was a surprise, also the condition of the heart, which was found small, but intact. Immediately after evacuation of the pleural effusion by puncture during life, the hitherto inaudible heart sounds became distinct, but they disappeared again as the pleural area of dulness increased.

Tracheal Hemoptysis. G. Avellis.—Obstinate constipation and hemorrhoids with violent straining at stool for years, resulted in a varicose condition of the veins in the anterior upper space between the rings of the trachea in a case described. The consequences were occasional hemorrhage from the dilated veins. The cause of the hemoptysis was surmised by Avellis from theoretical study of the conditions, and on examination the varicose veins were discovered at the point where he had anticipated finding them. Cauterization of the dilated veins soon cured the tendency.

Medicinal Phosphorus Poisoning. Nebelthau.—A child of 2 years took 3 mg. of phosphorus in the course of sixty hours, combined with cod-liver oil in the usual proportions. The child was well-nourished, but showed symptoms of rachitis. Symptoms of rapidly fatal phosphorus intoxication developed, confirmed by the pathologic changes in the organs. In future, Nebelthau proposes to reduce the proportion of phosphorus from .01 to .001 per cent., a teaspoonful twice a day, not increasing the dose until convinced of its harmlessness.

Wiener Klinische Wochenschrift, August 8.

Collateral Arterial Circulation after Complete Obliteration of all the Arteries at the Arch of the Aorta. W. Tuerk.—The origins of all the large arteries in the arch of the aorta were completely obliterated by an endo-arteritis on a basis of lues. The clinical picture was the exact reverse of what is observed in stenosis of the isthmus of the aorta. The patient was a baker's assistant, 44 years old. All the arteries in the trunk, head and extremities were almost if not entirely pulseless, while the cervico-abdominal aorta and the femoral arteries pulsated vigorously. The entire trunk, especially the back, was covered with dilated, tortuous and strongly pulsating arterial vessels, with an upward current. There was also a small aneurysm on the arch of the aorta compressing the left recurrent laryngeal nerve. The right coronary artery was also occluded. The only symptoms had been occasional pains, as from pressure, in the extremities and weakness, with slight transient vertigo on exertion. The arms toward the last became easily fatigued and the patient became emaciated, with symptoms indicating the small aneurysm. The remarkable feature of the case was that the symptoms were so few and slight when the supply of blood to the brain, neck and arms had been completely cut off for a long time, without essential functional disturbances.

August 15.

New Blotting-Paper Test of the Blood. S. Pertot.—The factors that enter into the absorption of fluids by a porous substance are both physical and chemical. Pertot suggests a new method of clinical diagnosis of the blood at the bedside, which is based on absorption, and is so simple and inexpensive that it is within the reach of every one. All that is required is a square of good blotting paper about the size of a playing card. A small amount of blood is aspirated in a pipette and mixed with water, in the proportion of 2.5 cm. to 1 cm. The blotting paper is placed on a sheet of glass and the pipette is placed inverted upon it, held perpendicularly in a small standard, just touching the paper. The fluid is slowly absorbed by the paper, and forms rings of various hues, the tints and size of the rings characteristic of the different composition of the blood. Two pipettes are always used, in one the blood is diluted with water from the faucet and in the other with distilled water, as the resulting pictures differ with these media, probably owing to the presence of salts in the undistilled water. Pertot has made hundreds of these blotting-paper pictures of the blood, and found them invariably identical under the same conditions of health and disease. The color fades in time, but the rings are still perceptible. The clearest pictures were obtained with the blood of new-born infants; their blood contains a larger proportion of reds than that of adults. Paper treated with dilute hydrochloric acid exhibits a picture resembling a narcissus flower.

Operative Evacuation of Mastoid Abscess with Schleich's Local Anesthesia. G. Alexander.—Eleven cases are described in which general narcosis was contra-indicated on account of pregnancy, pleuritis, nephritis, severe anemia, or other cause, and the operation was performed under local anesthesia alone in Politzer's clinic. The conditions of success are that the patient retain the same position throughout the entire operation and if pain is experienced, that he announce it to the operator without immoderate manifestations. These conditions were fulfilled in all but one case, and in this, the operation was successfully concluded in spite of the patient's restlessness. The ear affection had lasted from three weeks to eight months in the various cases. The amount of fluid used varied from 35 to 70 c.c., corresponding to 7 to 14 cg. of cocain, but as most of it is evacuated at once by the operation, very little can be absorbed. Each step of the operation is preceded by thorough infiltration of the soft parts down to the bone, especially of the attachment of the sterno-cleido-mastoid muscle, which is pushed back to expose the bone completely. The deeper portions of the bone are injected merely to anesthetize the granulations and swollen endostium. Solid bone is not sensitive. Chiseling the process is felt as a mere pounding, disagreeable, but not painful. The noise is reduced by covering the face of the mallet with gauze, and the patient's attention should be diverted at first by conversation with an attendant. The analgesia is not so complete as in general narcosis, but the superior advantages in certain cases are so marked that the method is recommended for all tranquil, trusting patients. Even nervous, excited patients may become tranquil during the operation. All the patients made a normal recovery. In five cases no pain was experienced and the patients had appetite for lunch. In the others, there was moderate pain in the wound or head. In two cases the patients vomited several times, and in one, radiating pains were experienced in the upper jaw for a time.

Xeroderma Pigmentosum. A. Halle.—Only two cases of complete recovery from this affection are on record, although a few authors have reported long survivals. Most of the subjects die in youth, generally from carcinoma cachexia. A personal observation is described in detail. On the basis of this case and those in the literature, Halle is convinced that the influence of sunlight in this affection has been exaggerated, and that it is a factor only in the initial erythema. The succeeding manifestations, the pigmented hypertrophy, the atrophy of the skin, the tendency to malignant proliferation of the epithelium, suggest the assumption of premature senility as a more plausible explanation of the cause of the disease.

Vratch (St. Petersburg), August 3.

Peritoneal Adhesions. E. Y. Katunsky.—Peritoneal adhesions in general, and especially the typical adhesion described by Gersuny, afford very important information in regard to abdominal affections and the organs of the abdominal cavity, including the female internal genital organs. It is of the greatest importance to determine the presence or absence of peritoneal adhesions before operating, and even before deciding on the method of operation. The existence of peritoneal adhesions—even if merely suspected—is an argument against the vaginal route. Much research is needed to establish the typical objective signs of various peritoneal adhesions, the origin, the clinical picture and the appropriate operation. Among the cases cited is that of a boy who was suddenly seized with vomiting spells eleven months after contusion of the abdomen. The appetite was good and there was no nausea, but pains appeared in the epigastric region four or five hours after eating. This region was also abnormally protuberant. The laparotomy showed that the upper surface of the transverse colon was adherent to the peritoneum and small intestine its entire length. In another case, in which the liver, gall-bladder and transverse colon were connected by peritoneal adhesions, the symptoms had been oppression and pains in the epigastric region after eating, nausea, vomiting, occasionally hemorrhagic, eructations with the odor of rotten eggs, and constipation. The patient was an adult with a history of contusion of the abdomen fifteen years before. The lesion had been diagnosed an ulcer of the stomach before operating.

[Gersuny's typical adhesion, described in the *Arch. f. Klin. Chir.* lix, p. 102, was discovered in twenty-one cases, all characterized by an identical clinical picture. The pseudo-membranous band is about 4 cm. long by 2 or 3 wide, and runs parallel with the outer layer of the mesocolon, from the point where the latter is attached to the intestine to its origin in the parietal peritoneum. The band may be adherent to the mesocolon or stretch above it like a bridge. In either case it prevents any movement of the intestine from the lateral abdominal wall toward the median line, and may cause volvulus, or invagination of the sigmoid flexure into the rectum, according as the sigmoid mesocolon is abnormally long or short. In other cases, the symptoms are constant pain in the lower abdomen, with violent pain in the left side just before defecation, and generally chronic constipation. The appendix was palpable and tender, and the left side still more sensitive at a symmetrical point. The pains were usually increased by movements, and consequently the working capacity was much diminished. According to the patients' stories there was no preceding illness, and the pains maintained their characteristics in spite of all kinds of treatment, for years, unmodified. In 2 cases there was a history of perityphlitis; in 1 an intestinal catarrh, and in 1 the pains were first noticed after lifting a heavy weight and persisted unchanged for six years until operated on. All but 3 were women, and Gersuny is inclined to attribute the adhesion to some effusion of blood into the peritoneum, occurring without symptoms, during menstruation or from trauma, in a certain proportion of the cases, which may likewise explain the etiology of appendicitis. Inflammation may develop secondarily to the formation of the adhesion and restriction of the movements of the appendix. The adhesion is not found unless carefully sought for, lifting up the colon and tracing the sensitive region inward from the anterior iliac spine. Irrigation and abdominal massage may be required to complete the cure. All Gersuny's patients were cured or very much improved by the operation.—Ed.]

Queries and Minor Notes.

CHAPARRO ARMAGOSO.

Cameron, Texas, Aug. 29, 1901.

To the Editor:—In reference to the query of S. A. F., in The Journal of August 24, I beg leave to submit the following:

Chaparro Armagoso is Spanish for bitter chaparro, a thorny bush that grows in Southern Texas and Northern Mexico. Synonym; armagoso; chaparro bush; goat bush.

Part used: bark of root. Natural order: Simarubaceæ. Properties: tonic, astringent, and somewhat antiperiodic.

It is much used in this section for chronic dysentery, and is an excellent remedy in doses of 30-60 minims of fluid extract. The history of its use is about as follows: It has long been used by the Mexicans in the form of a tea made from the root. A physician of Southwestern Texas, seeing the success attending its use, sent the root to one of the manufacturers, who prepared from it a fluid extract. It is prepared by Parke, Davis & Co., and perhaps by others. Respectfully, R. L. Jones, M.D.

TREATMENT OF TUBERCULOSIS WITH TUBERCULIN.

Denver, Sept. 2, 1901.

To the Editor:—In The Journal of July 13, page 151, there is a paper copied from a German medical journal, "Treatment of Tuberculosis with Tuberculin," by Dr. Goetsch. I am most anxious to get some of the tuberculin used by him for the treatment of cases now under my care. Could you tell me in next issue of The Journal or as soon as convenient where and how it may be obtained? And much oblige, Yours, etc., A. E. F.

Ans.—Koch's tuberculin T. R. can be obtained from Victor Koechl & Co., New York City. Dr. Goetsch used both the old and the new tuberculin. The original article was published in the *Deutsche Med. Wochenschrift*, June 20.

STATISTICS IN REGARD TO TYPHOID FEVER.

A correspondent is anxious to get the following statistics in regard to typhoid fever: 1. Number of cases that occur annually. 2. Number of deaths annually from typhoid. 3. Percentage of deaths from hemorrhage and perforation, respectively.

X-RAY DERMATITIS.

Waycross, Ga., Aug. 23, 1901.

To the Editor:—Can you advise me where I can get literature on constitutional effects (if any) of *x*-ray burns? I have a case in which the patient has developed various nervous troubles. I would also be pleased to have your opinion in regard to after-effects from *x*-ray dermatitis, and death of soft parts from same cause; does sloughing take place shortly after burn is received, or at a remote period? Thanking you in advance for courtesy,

Yours truly, R. P. I.

Ans.—Some cases are on record in which exposure up to an hour with non-focused tubes produced no inflammation of the skin, but accumulative effects from numerous exposures are to be borne in mind and feared. Single exposures of much less duration with focused tubes have been followed by severe burns of *x*-ray dermatitis. The symptoms of the mild form consist of inflammation, hyperemia, papules, vesicles, itching with marked pigmentation, loss of the fine lanugo hairs, and marked diminution of sweat and sebaceous secretions. This in turn may be followed by the graver condition characterized by sloughing of greater or less degree, dependent upon individual peculiarities. Dermatitis may appear any time from three to fourteen days after exposure, and sloughing may occur either during this or at a later period. A year or more may be required for recovery in the graver cases, and is accomplished usually either by skin grafting or cicatrization. The following references may be consulted: *Deutsche Medicinische Wochenschrift*, 1896, No. 30, p. 481 (Marcuse); ibid., No. 41, p. 665 (Sehrwald); ibid., No. 42, p. 681 (Marcuse); ibid., 1897, No. 7, p. 105 (Forster); ibid., No. 26, p. 417 (Mies); *Berliner Klinische Wochenschrift*, No. 23, 1898 (Behrend); *Johns Hopkins Bulletin*, February, 1897, 23 cases by Gilchrist. See various articles and abstracts in The Journal.

Books Received.

TRANSACTIONS OF THE MEDICAL ASSOCIATION OF GEORGIA. Fifty-second Annual Session, 1901. Cloth. Pp. 436. Atlanta, Ga.: Published by the Association. 1901.

THE ELEVENTH ANNUAL REPORT OF THE EYE, EAR, NOSE AND THROAT HOSPITAL, of New Orleans, La., *Jan. 1, 1900, to Dec. 31, 1900.* Paper. Pp. 53. New Orleans: L. Graham & Son, Ltd. 1901.

THE FOOD VALUE OF MEAT. FLESH FOOD NOT ESSENTIAL TO MENTAL AND PHYSICAL VIGOR. Illustrated. By W. R. C. Latson, M.D., editor of Health-Culture. Cloth. Pp. 72. Price, 50 cents; paper, 25 cents. New York: The Health-Culture Co.

THE [illegible] (Remittent) MALARIAL FEVERS. By Charles [illegible] Acting Assistant-Surgeon, U. S. A. Illustrat[illegible] and 21 Clinical Charts. Cloth. Pp. 221. Price, $2.50. New York: William Wood & Co. 1901.

PRACTICAL FIRST PRINCIPLES. Simplifying the Study of Normal and Abnormal Structure and Function, and Aiding *Diagnosis.* Designed for the Use of Students and Practitioners of Medicine. By A. H. P. Leuf, M.D., Associate Editor of the *Medical Council.* Cloth. Pp. 105. Price, $1.00 net. Philadelphia: The Medical Council. 1901.

THE READY REFERENCE HANDBOOK OF DISEASES OF THE SKIN. By George Thomas Jackson, M.D., Chief of Clinic and Instructor in Dermatology, College of Physicians and Surgeons, New York. With 80 Illustrations and 3 Plates. Fourth Edition, thoroughly revised. Cloth. Pp. 642. Price, $2.75. New York and Philadelphia: Lea Brothers & Co. 1901.

New Patents.

Patents of interest to physicians, issued August 20 and 27:

680,689. Device for distributing odors. Charles T. Bradshaw, Philadelphia.

681,100. Disinfectant holder. Daniel N. Calkins, Rochester, N. Y.

680,723. Depurator. Ruth J. Maurer, La Crosse, Wis.

680,936. Bristle probang. Richard P. McCully, Brooklyn, N. Y.

680,814. Invalids' bed. Patrick C. Smith, Indianapolis, Ind.

680,898. Machine for impregnating thread with virus. O. Thomas, Verdun, France.

681,174. Treating curvature, etc. K. Wegner and E. Repke, Berlin, Germany.

681,010. Vaginal syringe. Frank Y. Wilhoft, New York City.

34,964. Design, electrotherapeutic device. B. G. Stauffer, Harrisburg, Pa.

681,664. Exercising apparatus. John S. Addleman, Cleveland, Ohio.

681,387. Speculum and medicine distributor. Martin Bohlig, St. Paul, Minn.

681,494. Chin rest for ophthalmometers. John E. Chambers, Chicago, Ill.

681,622. Respirator. Harvey S. Cover, South Bend, Ind.

681,498. Separator for cellulose. Robert Dietrich, Merseburg, Germany.

681,631. Bath cabinet. Warren A. Durrin, Woodville, Wis.

681,483. Sterilized surgical dressing. Henry C. Lovis, New York City.

681,568. Making ammonium ichthyol sulfonate. A. C. McLaughlin, Austin, Tex.

681,505. Quinin methyl-dihydrazin perchlorate and making same. Max Meyer, New York City.

681,331. Combination massage roller and exerciser. Geo. W. Milkman, New York City.

681,333. Spitting pot. John F. T. Mjoen, Christiania, Norway.

681,338. Ether inhaler. Gustav Otto, Jersey City, N. J.

681,463. Apparatus for treating diseases. H. E. Waite, New York City.

681,289. Apparatus for rendering water pure. J. S. Wrightnour, Oil City, Pa.

34,994. Design, inhaler. Moriz Bauer, Vienna, Austria-Hungary.

34,995. Design, bag for ice or water. C. W. Meinecke, Jersey City, N. J.

The Public Service.

Army Changes.

Movements of Army Medical Officers under orders from the Adjutant-General's Office, Washington, D. C., August 22 to 28, 1901, inclusive:

John R. Clark, contract surgeon, from duty at the General Hospital, Presidio of San Francisco, Cal., to his home in New York City, for annulment of contract.

Guy L. Edie, major and surgeon, U. S. A., sick leave extended.

William R. S. George, contract surgeon, to proceed to Ponce, P. R., for duty during the absence on leave of Captain Benjamin Ten Eyck; on completing this duty he will rejoin his proper station, San Juan, P. R.

William O. Owen, major and surgeon, U. S. A., leave of absence granted.

James Reagles, contract surgeon, leave of absence from the Department of the Columbia extended.

Roy A. Wilson, contract surgeon, previous orders requiring him to proceed to San Francisco, Cal., en route for duty in the Philippines revoked.

Navy Changes.

Changes in the Medical Corps of the Navy, week ended Aug. 31, 1901:

P. A. Surgeon R. M. Kennedy detached from the *Bennington* when placed out of commission, and ordered home.

P. A. Surgeon D. H. Morgan, detached, from the *Monongahela, and ordered to the* Naval Hospital, Newport, immediately, for treatment.

Asst.-Surgeon R. T. Atkinson, detached from the Washington Hospital, and ordered to the *Wabash,* immediately.

Asst.-Surgeon A. W. Balch, detached from the *Wabash* and ordered to the *Monongahela,* immediately.

Medical Inspector D. N. Bertolette, detached from the *New York and ordered to the Brooklyn* as Fleet Surgeon.

Surgeon J. E. Gardner, detached from the *Brooklyn* and ordered to the *New York.*

Asst.-Surgeon J. M. Brister, assigned to the Marine Brigade, Asiatic Station.

Marine-Hospital Changes.

Official list of the changes of station and duties of commissioned and non-commissioned officers of the U. S. Marine-Hospital Service, for the seven days ended Aug. 29, 1901:

Surgeon Preston H. Bailhache, detailed as delegate to represent the service at the meeting of the American Public Health Association, to be held in Buffalo, N. Y., September 16-20.

P. A. Surgeon A. C. Smith, granted leave of absence for one day, Aug. 21, 1901, under paragraph 181, Regulations, U. S. Marine-Hospital Service.

A. A. Surgeon W. C. Todt, granted leave of absence for 14 days *from August 18.*

Hospital Steward F. S. Goodman, granted leave of absence for thirty days from September 1.

Hospital Steward C. A. Warhanik, granted leave of absence for thirty days from September 4.

Hospital Steward L. P. Hall, relieved from duty at Boston, Mass., and directed to proceed to Vineyard Haven, Mass., and report to medical officer in command for duty and assignment to quarters.

RESIGNATION.

Hospital Steward C. A. Warhanik resigned, to take effect Oct. 4, 1901.

Health Reports.

The following cases of smallpox, yellow fever, cholera and plague have been reported to the Surgeon-General, U. S. Marine-Hospital Service, during the week ended Aug. 31, 1901:

SMALLPOX—UNITED STATES.

California: San Francisco, Aug. 11-18, 1 case.

Illinois: Freeport, Aug. 17-24, 1 case.

Maine: Aroostook County, Aug. 2, present.

Massachusetts: Boston, Aug. 17-24, 5 cases, 2 deaths.

New Jersey: Newark, Aug. 17-24, 5 cases, 2 deaths.

Pennsylvania: Philadelphia, Aug. 17-24, 7 cases, 1 death; Pittsburg, Aug. 19-24, 1 death.

Wisconsin: Green Bay, Aug. 18-25, 3 cases.

SMALLPOX—FOREIGN.

Brazil: Rio de Janeiro, July 14-28, 64 deaths.

Canada: Woodstock, District, Aug. 2, 80 cases.

Colombia: Panama, Aug. 12-19, 7 cases.

Ecuador: Guayaquil, June 12-22, 3 deaths.

Great Britain: London, Aug. 2-10, 11 cases, 1 death.

India: Bombay, July 23-30, 2 deaths; Calcutta, July 20-27, 4 deaths; Madras, July 20-26, 3 deaths.

Italy: Messina, Aug. 3-10, 5 cases, 2 deaths; Naples, Aug. 4-11, 123 cases, 26 deaths.

Japan: Osaka and Hiogo, July 22-27, 1 case.

Netherlands: Rotterdam, July 27-Aug. 10, 3 cases.

Spain: Malaga, July 1-31, 2 deaths; Valencia, July 27-Aug. 3, 11 deaths.

Straits Settlements: Singapore, July 13-20, 1 death.

Uruguay: Montevideo, July 6-20, 43 deaths.

YELLOW FEVER.

Brazil: Rio de Janeiro, July 14-20, 7 cases.

Cuba: Havana, Aug. 10-17, 1 case, from Fincia Riquena.

Mexico: Tampico, July 26-Aug. 2, 2 cases, 1 death; Vera Cruz, Aug 10-17, 6 cases, 2 deaths.

CHOLERA.

India: Bombay, July 23-30, 5 deaths; Calcutta, July 20-27, 22 deaths; Madras, July 20-26, 1 death.

Japan: Yokohama, July 31, 1 case.

Java: Batavia, July 13-20, 10 cases, 6 deaths.

PLAGUE—INSULAR.

Philippines: Manila, July 6-13, 12 cases, 10 deaths.

PLAGUE—FOREIGN.

Brazil: Rio de Janeiro, July 20-28, 3 deaths.

India: Bombay, July 23-30, 113 deaths; Calcutta, July 20-27, 16 deaths; Karachi, July 21-28, 5 cases, 7 deaths.

A METHOD OF TEACHING RELATIONAL ANATOMY.*

C. M. JACKSON, M.S., M.D.
ASSISTANT PROFESSOR OF ANATOMY, UNIVERSITY OF MISSOURI.
COLUMBIA, MO.

For many centuries the science of anatomy has been universally recognized as the foundation for the study of medicine. It is, therefore, evident that the best method of studying and teaching this fundamental subject is a problem of great importance. To anatomy belongs the credit of being the first science to adopt the objective, or laboratory method of study. Anatomists long ago insisted that the only way to gain real knowledge of anatomy is by dissection. The art of dissection has therefore been diligently cultivated for many centuries, and the practical limit of its development was reached nearly one hundred years ago. Indeed, the anatomists of the present day are perhaps inferior in the art of dissection to those of the previous generation. This is undoubtedly due to the increased attention paid in recent years to the related subjects of comparative anatomy and embryology, and to the new world of facts revealed in microscopic anatomy or histology. The effect of these studies has been to revolutionize the science of anatomy, so that its present scope and significance are perhaps better expressed by the more comprehensive term, morphology.

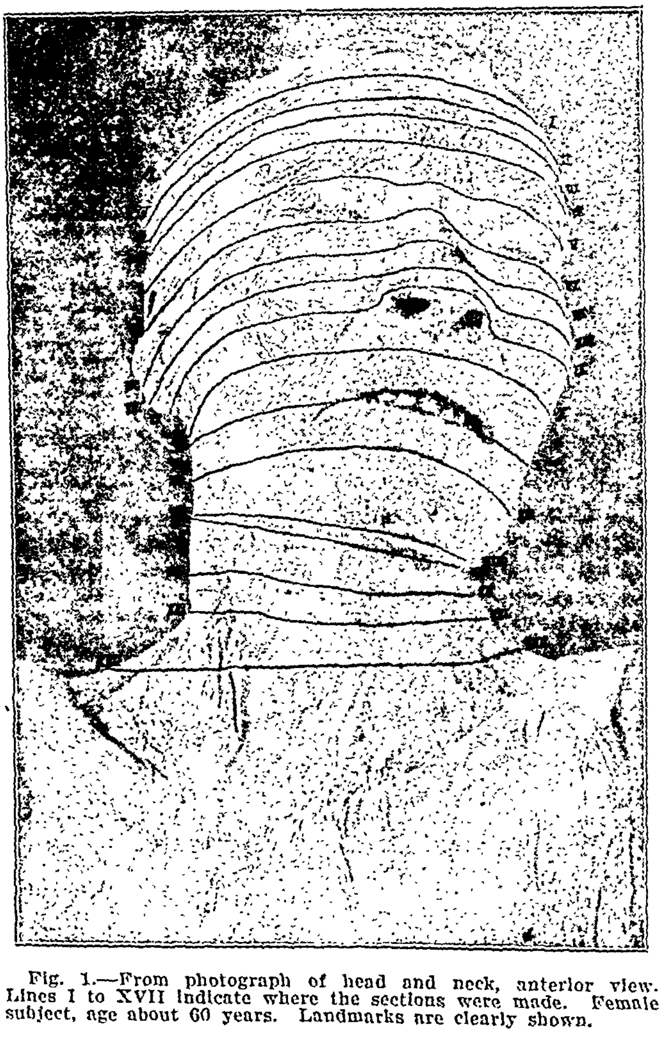

Fig. 1.—From photograph of head and neck, anterior view. Lines I to XVII indicate where the sections were made. Female subject, age about 60 years. Landmarks are clearly shown.

Yet, with all the time spent in dissection, and in spite of the flood of light thrown upon the subject by recent advances in comparative and microscopic studies, we still fail to accomplish the desired end. The ambition of the student of anatomy is, or should be, the ability to *see through* the body, perceiving in the mind's eye all the structures included therein, and their complicated relations to each other. This ability the student must gain somehow, if he is to achieve real success in medicine or surgery; for upon this knowledge are based both physical diagnosis and surgical procedure.

Bearing this in mind, and also the fact that the average medical graduate is very deficient in his knowledge of anatomy from this standpoint, it must be admitted that there is something wrong with our present and past methods of teaching the subject. Wherein do we fail? The reason, it seems to me, lies in the fact that in all the time we devote to the study of the various branches of anatomy—comparative anatomy, osteology, dissection, descriptive anatomy, histology, embryology, etc. — in all these branches we spend practically our entire time upon the study of the individual organs and organ-systems, while practically no time is spent in considering the anatomical relations of these organs to each other, and to the surface of the body. To me it seems clear that so long as this is true, the student's knowledge of anatomy, at least from the standpoint of medicine, must necessarily remain incomplete and unsatisfactory.

This being true, the question arises: What method can we use to study what we may term the relational anatomy of the various organs? Take the liver, for example. How shall we proceed to study the exact spatial relations of the liver to the neighboring structures, such as the stomach, kidneys or lungs; and how shall we determine its relations to the surface of the body? It is evident that the ordinary methods of dissection give us very imperfect knowledge in this regard, for in the very act of dissection we must necessarily remove those surrounding structures whose relations it is so important to determine. There is, I believe, only one way in which relational anatomy can be thoroughly, systematically and satisfactorily studied; and that is by means of sections made in various planes in the different regions of the body. Only by this method are the organs made visible in their actual spatial relations to each other. This is by no means a new method of investigation. It has long been used in histology and embryology, where objects are too small or too delicate to be studied otherwise. It has also been applied, to a very limited extent, to the gross anatomy in a few special regions of the human body.[1] But on account of certain difficulties in the application of the method, it has never come into general use. The method which I have to present, therefore, while old in principle, is new in its application; since, so far as I am aware, in no other laboratory of anatomy is it made a regular part of the system of instruction.

---

* Read at the Fifty-second Annual Meeting of the American Medical Association, in the Section on Surgery and Anatomy, and approved for publication by the Executive Committee of the Section: W. J. Mayo, H. O. Walker, and A. J. Ochsner.

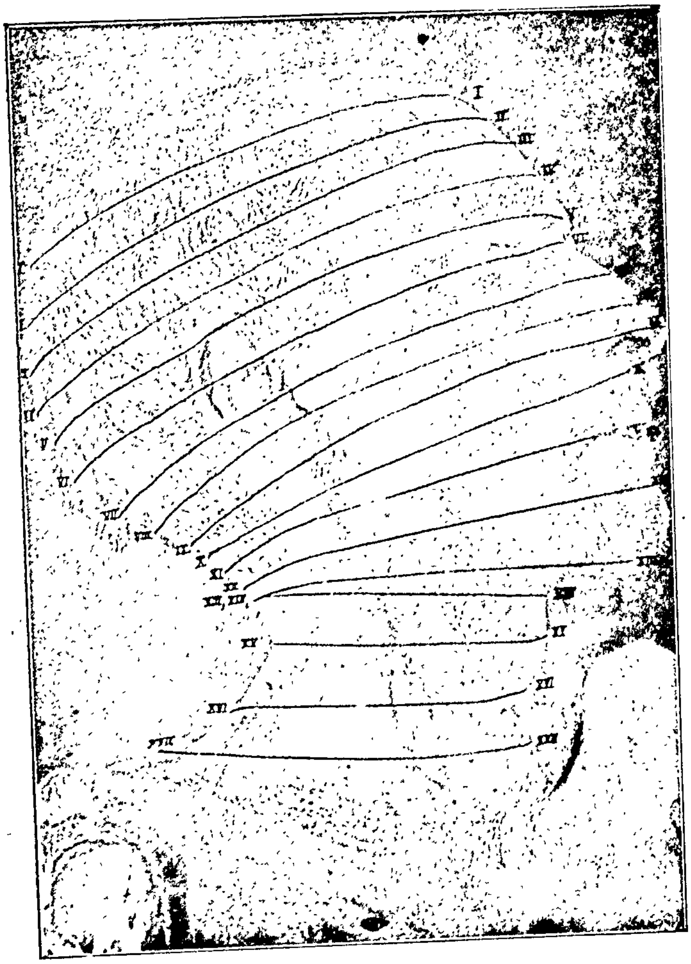

Fig. 2.—Lateral view of the head and neck, photographed from the same subject as Fig. 1.

The plan which I have worked out for instruction in relational anatomy involves the following consecutive steps: 1. Hardening of cadavers. 2. Study of surface form. 3. Making of sections. 4. Study and drawings of sections. 5. Reference to literature. 6. Written report of results.

Hardening of Cadavers.—Suitable cadavers, selected especially for this work, are injected, not with the usual embalming liquids, but with 50 per cent. formalin, that is, pure formalin (40 per cent. formaldehyde) diluted with equal volume of water. I inject about one gallon, or more if possible, of this liquid into the arteries, usually through the common femoral. This may be followed in a few hours by a second colored injection mass, if desired. Within a few days all the softer tissues of the body become thoroughly hardened. Every organ is thus fixed perfectly in the exact shape and position it occupied during life. Sections may be made at any time after one week. If the cadaver is to be kept some time before using, all that is necessary is to apply vaselin to the skin and wrap with oil muslin bandages to prevent drying. The cadaver will then preserve perfectly, at any temperature, for an indefinite time.

Study of Surface Form.—For the work in relational anatomy, the class—which has previously completed its dissections by the ordinary method—is divided into groups of two, who work together. Two are assigned to the head and neck, two to the thorax, two to the abdomen, and two to each arm and leg. The first thing that each student does is to make a very thorough study of the surface form of the region to which he is assigned. Special stress is laid upon the landmarks, whose relations to the underlying structures are of great importance. The student makes careful measurements, and records his observations in a note-book kept for the purpose. A mounted skeleton, an Auzoux manikin, and various other models are at hand for comparison.

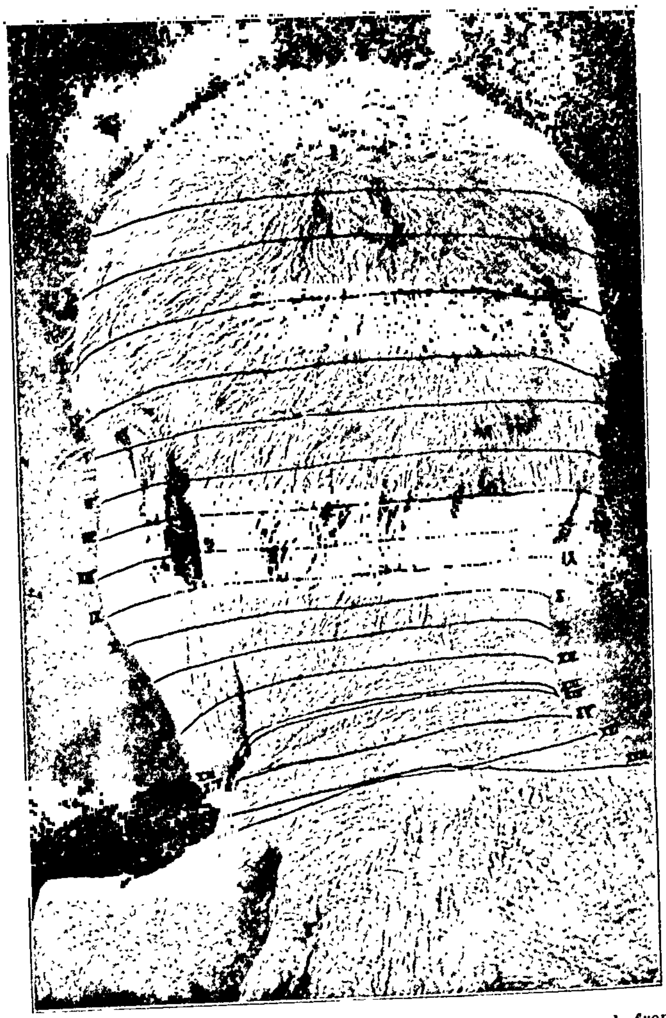

Fig. 3.—Posterior view of the head and neck. Photograph from same subject shown in Figs. 1 and 2.

At this point, photographs are taken showing different views of each region. A set of these photographs is supplied to each student, and they serve a double purpose. In the first place, they furnish an exact picture record of the surface form; and secondly, by means of reference lines drawn later in ink, they serve to indicate the exact level and plane of each section taken. This is a very important feature. In case the photographs were not obtainable, it would be necessary to make very careful outline drawings, upon which the landmarks and reference lines would be shown.

---

[1] Braune, Macewen, Dwight, and others, have made sections for the investigation of relational anatomy, chiefly by the freezing method.

Making of Sections.—Having carefully studied the surface form, and having a record of his observations in notes and photographs, the student now proceeds to cut sections through the body in the desired planes. As soon as made, the sections should be thoroughly washed with water, taking care not to displace any organs. Blood-clots, fecal material, excess of formalin, etc., are thus removed. Cross sections of the extremities are best made at definite intervals, every half inch or inch. In the head, the sections need not be more than one-fourth inch apart. In the trunk, sections should be somewhat thicker. I have found that it facilitates the handling of sections, and especially the problem of determining the exact level of a given structure, if the sections in the trunk region be made to pass through the intervertebral disks. Then each slice corresponds to the body of a vertebra. It is remarkable how well sections made by this method will hold together, even when they pass through the intestines. Occasionally a piece becomes loose or detached, but it is easily secured in place by a stitch of thread. In the head and trunk, and a few special regions, besides cross sections, coronal and sagittal sections are also necessary. Wherever possible, consecutive sections are left attached to each other at one edge by the skin. The sections are made with a long butcher knife and an ordinary butcher's saw (for bones). If the tissues are thoroughly hardened, the sections are easily and smoothly made.

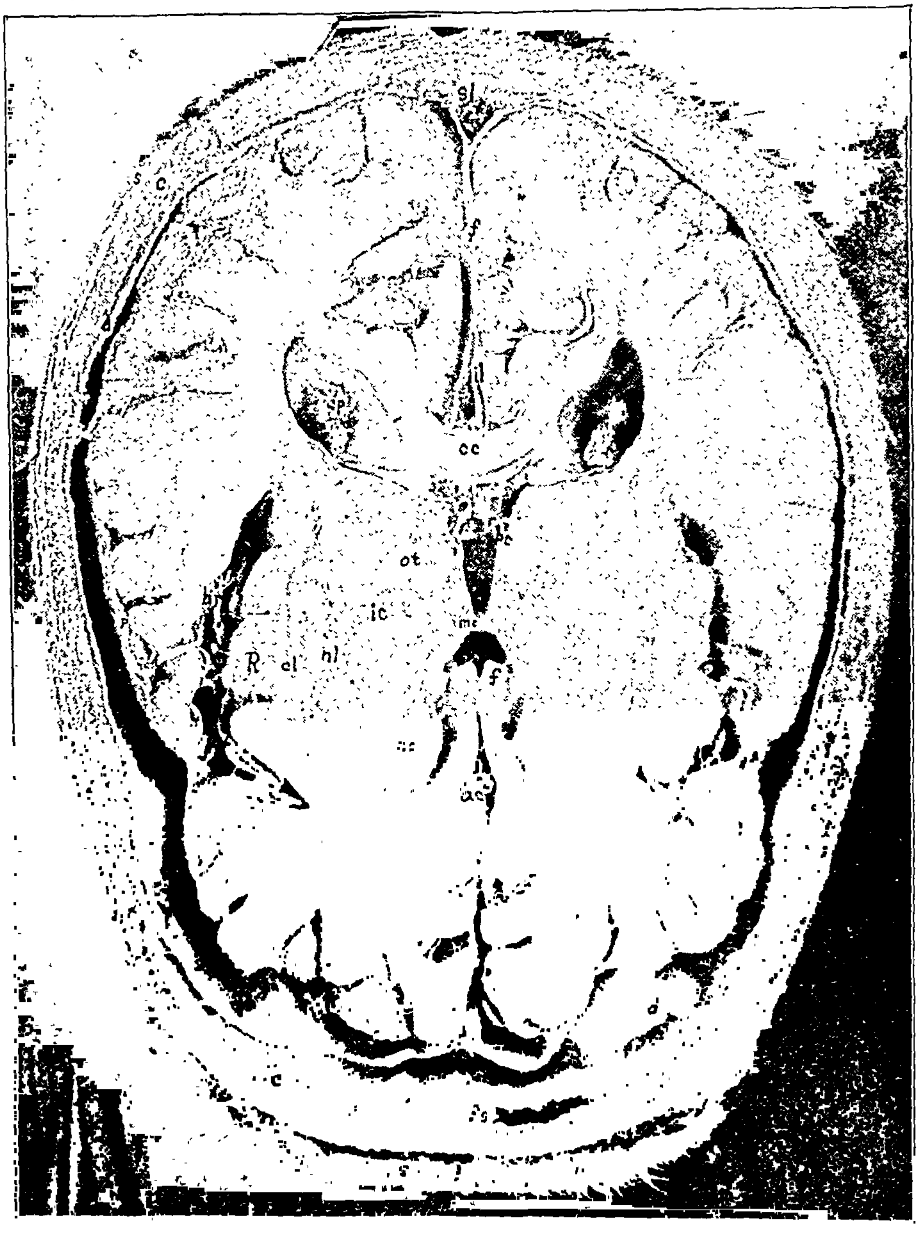

Fig. 4. From photograph showing horizontal section through the head, viewed from above, at the level indicated by reference line III, in Figs. 1, 2 and 3. Section passes through the frontal, temporal, and occipital lobes, and the Island of Reil. *s*, Scalp; *c*, cranium; *d*, dura mater; *p*, pia mater; *fs*, frontal sinus; *f*, falx cerebri; *sl*, sup. longitudinal sinus; *il*, inferior longitudinal sinus; *ac*, anterior cerebral arteries; *br*, branches of middle cerebral arteries; *r*, Island of Reil; *f*, fornix; *cc*, corpus callosum; *cp*, choroid plexus in lateral ventricle; *mc*, middle commissure (in 3d ventricle); *pc*, posterior commissure; *ot*, optic thalamus; *ic*, internal capsule; *nc*, nucleus caudatus; *nl*, nucleus lenticularis; *cl*, claustrum.

In this connection, I may remark that this formalin method offers several advantages over the method of frozen sections. No freezing is necessary; the sections are made more easily and smoothly; and, finally, they do not thaw out and become loose or flabby upon handling. This method is also superior to all embedding methods, since not only the surfaces of the sections, but also the structures between, are accessible for examination. In fact, it combines the advantages of dissection with those of plane sections.

In some cases it is advantageous to *combine* the formalin and freezing methods by first hardening the cadaver thoroughly with formalin, as above outlined, and then making the sections by the freezing method.

Dr. Terry[2] has suggested that the bones be decalcified with acids, thus avoiding the use of a saw. This is perhaps admissible in the head region, where dense skeletal parts are so closely related to delicate organs; but elsewhere, I consider it desirable for the student actually to saw through the bones upon reaching them. The location and physical characters of the skeleton are thereby more firmly impressed upon his mind. Even through the head region, as the accompanying figures show, excellent sections can be made without decalcification, which is therefore necessary only when very thin sections are desired.

Study and Drawing of Sections.—After the sections are cut, the student begins the most important part of his work, viz., the study of the sections. Every structure which appears in each section must be identified, every nerve and blood-vessel followed. The position of the various organs with respect to each other, and to the surface, must be carefully observed and recorded in a note-book. The sections are studied first separately, and later collectively, by placing them together in their natural order. Finally, in order to impress the relations more strongly upon the student, he is required to make a careful outline drawing of each section. We have adopted for this work a method of drawing which makes it easy and at the same time very accurate. A piece of plate glass in an open frame is laid directly upon the section which is to be drawn. Then, by means of pen and India ink, the outlines are traced, showing all the organs visible through the glass, in their exact relations. When the ink is dry, a sheet of drawing paper or bristol board of the proper size, is placed in the frame and fastened by an inner frame behind the glass which contains the ink outline (See Fig. 8). Upon holding up the frame toward the light, the ink outline shows through distinctly, and can readily be traced with a pencil upon the drawing paper. At night the drawings are readily transferred by placing the frame over an electric light. The principle of tracing upon glass was suggested by one of my students, the drawing frame being an invention of my own. The most difficult and important part of the drawing, an accurate outline of the various structures, is now upon the drawing paper. The pencil outline is retraced with ink, and the details are readily filled in with ink, water colors, etc., according to the taste of the individual student. These drawings are very highly prized by the students, and, indeed, form a valuable set of plates for future reference.

---

[2] Proceedings of the Association American Anatomists, W ington, D. C., 1900.

Every structure appearing upon these drawings is, of course, carefully labeled, and the reference line on the photograph showing the plane of the section is also indicated by numbers.[3] For the sake of uniformity, every drawing should represent the *upper surface* of the section, unless there is a special reason for the contrary. Moreover—and this is a point upon which I insist strongly—every section should be studied and drawn in the position it would occupy if the cadaver were facing the student, that is, with the *ventral* body wall *nearest*, and the dorsal wall on the further side of the drawing. Some uniform method of position is necessary, both in studying and in drawing, otherwise no clear and permanent mental images can be formed. How could one form any idea of geographical location from maps, if the top of the map sometimes indicated north, sometimes south, sometimes east, and sometimes west? The reason for placing the dorsal side of an anatomical figure toward the top of the page is because that represents (when the drawing is held upright) the typical vertebrate position: dorsal surface upward and ventral surface downward. Since a thorough study of human anatomy, is impossible without reference to comparative anatomy, the same standard of position should be adopted for both.

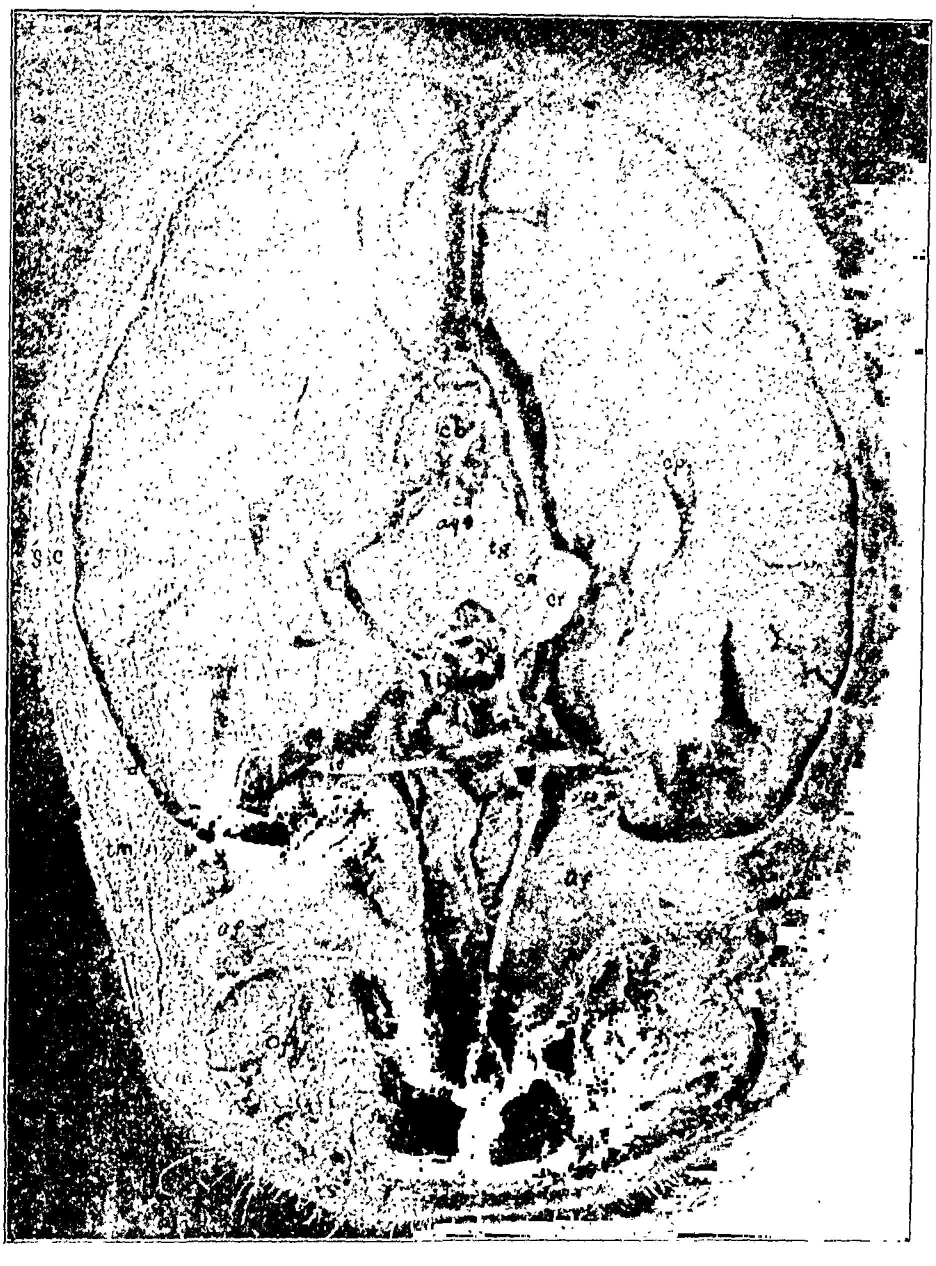

Fig. 5.—From photograph showing horizontal section, viewed from above, through the head at the level indicated by line IV in Figs. 1, 2 and 3. This section passes through the temporal and occipital lobes, and the upper part of the orbital cavity. *s*, Scalp; *c*, cranium; *tm*, temporal muscle; *d*, dura mater; *f*, falx; *t*, tentorium; *sl*, sup. long. sinus; *il*, inf. long. sinus; *of*, orbital fat; *c*, ethmoidal cells; *fs*, frontal sinus; *cg*, crista galli; *ob*, olfactory bulb; *af*, anterior fossa; *ic*, internal carotid; *cp*, choroid plexus of lateral ventricle; *cq*, corpora quadrigemina; *aq*, Sylvian aqueduct; *sn*, substantia nigra; *cr*, crusta; *tg*, tegmentum; *cb*, cerebellum.

Reference to Literature.—The student has now studied and compared his sections, and finished his drawings of them, but still his task is not completed. He has yet to compare his own work with the results of other investigators. To do this he is required to look up references concerning the relational anatomy of the region in the various books and periodicals in the department library. He takes notes here also, and finds, often to his astonishment, that the authors sometimes disagree with each other, and also with the facts as he *knows* them to be in his own sections. Thus he learns the important lesson that the real source of knowledge is Nature, not books.

---

[3] A blue print copy of every drawing, and a duplicate of each photograph, are preserved by the laboratory as a record for reference in the future.

Written Report of Results.—Finally, in order to get his knowledge arranged in a systematic way, the student is required to write a report in which he sums up briefly and clearly, the results of his own observations, and compares them with the statements found in the literature. The writing of this paper, which is, of course, accompanied by the explanatory photographs and drawings, forms an excellent review of the entire subject, and puts the work of the student in a convenient form for future reference.

Besides the thorough study of one region, according to the method outlined, the student is required to review the remainder of the body from sections already made. Thus he becomes familiar with the more important topographic relations of the entire body. More advanced work in topographical anatomy is assigned to students who wish to make a special study of the subject.

In conclusion, allow me to suggest that this method for the study of relational anatomy will be of the utmost value to practitioners who are not located conveniently near anatomical laboratories, but still desire to devote some time to the study of anatomy, especially in its relations to surgery. The method is simple, the apparatus inexpensive, the material keeps indefinitely, and the knowledge gained from a study of the body in this way can hardly fail to be of great practical value. Drying of the sections is the only trouble to be guarded against. This may be prevented, 1, by placing a cloth wet with some slightly antiseptic liquid between every two sections, when not in use; 2, by wrapping the entire part in water-proof cloths; 3, by keeping the sections in an air-tight receptacle, either box, can or jar. Formalin sections dry much less rapidly than alcoholic specimens, however, and can be exposed to the air for two or three hours without damage.

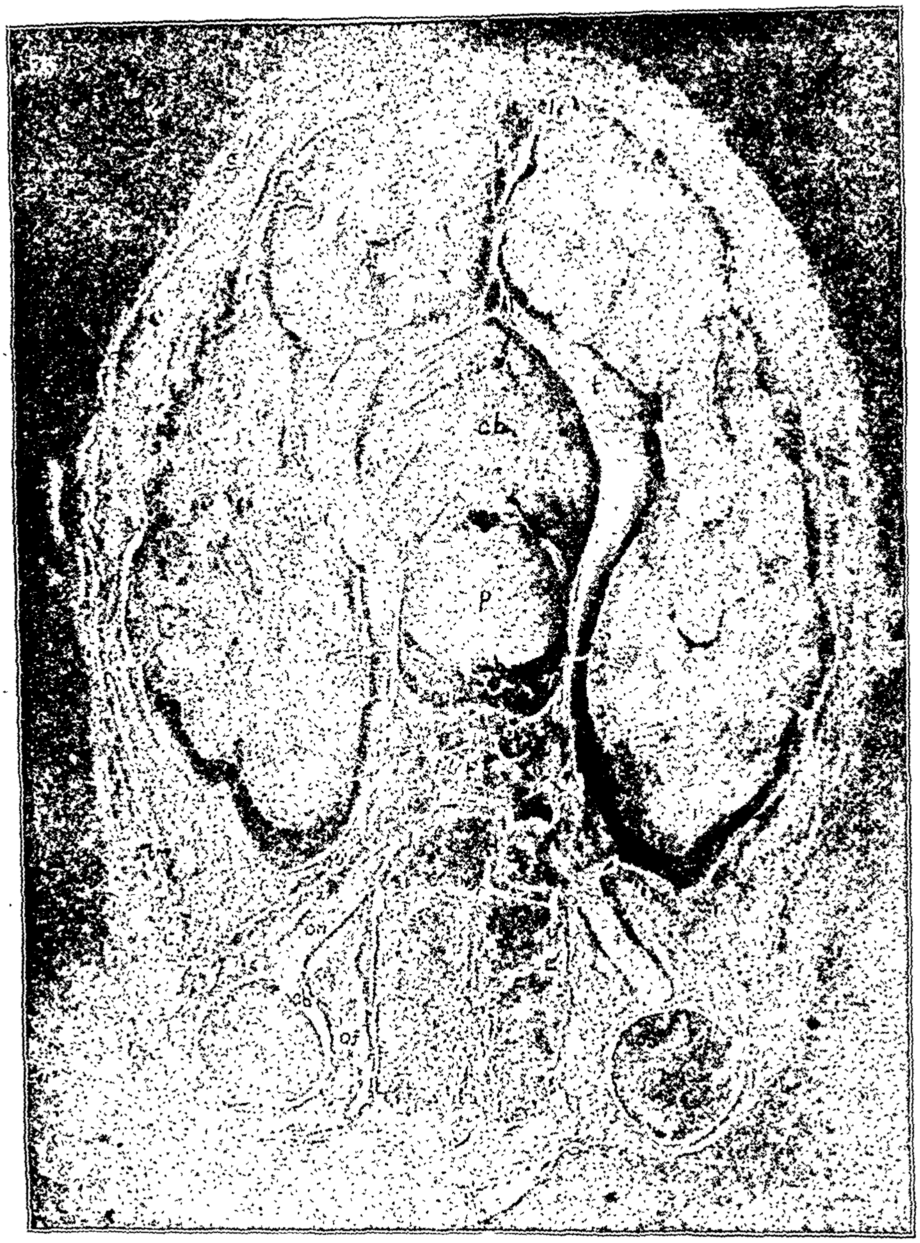

Fig. 6.—From photograph showing horizontal section, viewed from above, of the head at level indicated by line V in Figs. 1, 2 and 3. Section passes through temporal and occipital lobes, and just above the center of the eyeball. *s*, Scalp; *tm*, temporal muscle; *c*, cranium; *n*, nose; *f*, falx; *sl*, sup. long. sinus; *il*, inf. long. sinus; *t*, tentorium; *cb*, eyeball (retina shrunken); *of*, orbital fat; *on*, optic nerve; *e*, ethmoidal cells; *s*, sphenoidal cell; *ic*, internal carotid; *pt*, pituitary body; *b*, basilar artery; *p*, pons varolii; *aq*, aqueduct of Sylvius; *cb*, cerebellum. (Figs. 7 and 8 in following article.)

An Italian Professor Exonerated.—Professor D'Antona, of Naples, was recently accused by the relatives of having caused the death of a patient by overlooking a gauze compress in an operation on the liver. A committee of investigation was appointed by the Senate, who have honorably exonerated the surgeon from the slightest blame. The patient had malignant disease of the liver, and in operating, a gauze drain was purposely left. The patient left the hospital contrary to his wishes, and her death soon after was attributed to the gauze.

Rovsing's Ablation of the Stomach. — In Rovsing's patient the discovery of the carcinomatous condition of the stomach was a laparotomy surprise. He found it necessary to remove the entire stomach with a portion of the esophagus. The stump of the latter slipped up through the diaphragm and union with the duodenum proving impracticable, he sutured it to a loop of the jejunum, 40 cm. from the duodeno-jejunal angle, inserting the esophagus in a longitudinal incision 12 cm. in length. The patient showed signs of collapse at first, and slight phlebitis was observed during convalescence. Recovery was uneventful.

THE AIM OF MEDICAL EDUCATION, AND ITS RELATION TO RESEARCH WORK, BY MEDICAL STUDENTS.

W. S. CHRISTOPHER, M.D.
Professor of Pediatrics, College of Physicians and Surgeons of Chicago (Medical College of the University of Illinois); President of the American Pediatric Society.
CHICAGO.

The work of the medical colleges twenty years ago was such that almost any change in it was a change in the direction of improvement. The result was that as changes were suggested, they were hailed with delight, and adopted as rapidly and as thoroughly as the different schools could accommodate themselves to them, until it has now almost become a habit to accept as good and desirable any innovation in medical college work which may be suggested. The last two decades have seen a general extension of the time of medical study from two courses of five months each to four courses of eight or nine months each; this period has seen introduced into the curriculum many branches of study, previously never attempted; it has seen the standard of admission raised, and the requirements for the degree, and for the right to practice made more stringent. During the same time the subject of laboratory work has practically had its whole development in our American schools, excepting only certain work in dissection, and some very rudimentary *chemical work*. The didactic lectures of the older days have been severely criticised, and the recitation method has found many advocates. and some application. So numerous and far reaching have these changes been in so short a time, that we must admit that we are in the midst of "boom times" in medical education. And "boom times" are not without their dangers; their products are not always solid. A mere glance at the changes show that they involve standards of admission to professional study, subject matter of such *study, methods of teaching*, and the relations of the profession to the community. Each of these factors is complex; it has many sides and many relations, pedagogical, professional, and social, not all of which are apparent at a glance, and some of which can only be determined as time and experience reveal them. It would seem, therefore, wise to stop occasionally and review the situation broadly and compare our position with fundamental landmarks, to take our bearings and determine if possible if our progress is all that we fondly think it to be.

I propose here to take bearings from just one fundamental landmark, for the light which it may throw on the situation, and compare it with one proposed innovation. The landmark to which I refer is the one which defines the province of the physician and thereby establishes the functions, duties, and scope of the medical college, the place where he is prepared for his life work. The province of the physician is to prevent and relieve sickness, and to prolong life. To perform his functions he must be familiar with the nature and cause of disease—pathology; have the skill and means for determining its various phases—diagnosis; be armed with the best means for combating it—therapy; and be possessed of good professional judgment to guide him in his art. His pathology must be based upon anatomy, physiology and chemistry, the two former of which must be acquired within the walls of the medical school, simply because they have not yet become subjects of such widespread study for purposes of general culture that they can generally be acquired in other institutions, and

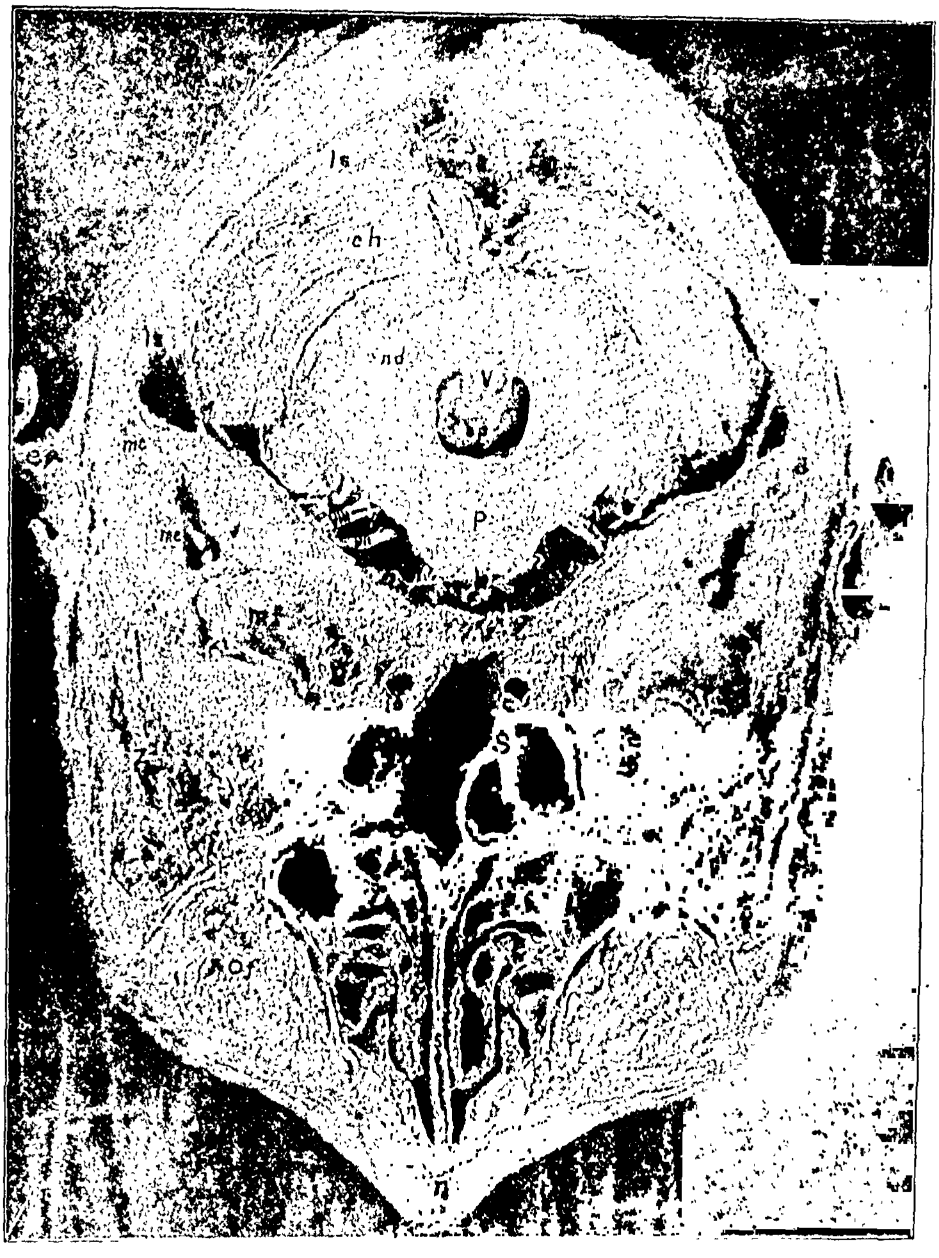

Fig. 7.—From photograph of horizontal section, viewed from above, of the head at the level of line VI, in Figs. 1, 2 and 3. This section passes below the cerebrum, striking the cerebellum middle ear and lower part of the orbit. ygomatic arch; *n*, nose; *of*, orbital fat; *s*, nasal septum; *v*, vomer; *c*, trum of Highmore; *s*, sphenoidal cells; *io*, internal carotid; *b*, basila ganglion; *mf*, middle fossa; *mo*, middle ear, showing chain of bones; lateral sinus; *ch*, cerebellar hemisphere; *nd*, nucleus dentatus; *v*, vermis; *cp*, choroid plexus of the 4th ventricle; *p*, pons varolii; *VII*, 7th cranial nerve; *VIII*, 8th cranial nerve.

not because they are subjects of exclusive medical interest or use. For the same reason that chemistry, to have its truly medical aspect emphasized, is still taught in medical schools, anatomy and physiology will probably also continue to be taught there even when their study in institutions of general learning becomes much more extensive than it is now. The pathology of the medical student must always be taught in the medical schools. It constitutes a very large percentage of the subject matter of the curriculum, and demands a large part of the student's time. The subject is divided among many chairs, the etiological portions going to one or more departments, the general and comparative aspects to other departments, while special features are presented by the so-called practical chairs, or what should more properly be spoken of as the philosophical chairs. In all of this work the student is gathering data, is securing information, of the importance of which he is but illy qualified to judge.

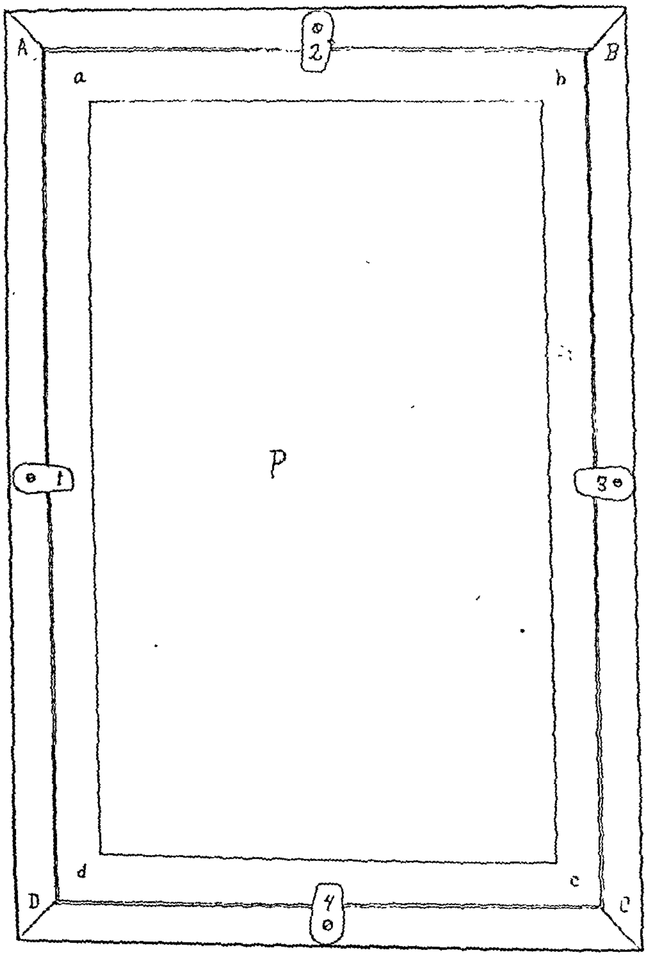

Fig. 8.—A diagram of the Drawing Frame. *abcd*, The *outer* frame, which resembles an ordinary picture frame, in which the glass and drawing *paper are placed*; *abcd*, the *inner* frame, which fits into the outer *frame behind* the glass and drawing paper, holding them firmly in place: 1, 2, 3, 4, wooden "buttons," fastened each by a screw into the outer frame, and serving, when turned as in figure, to hold the inner *frame tightly* behind the glass and paper: *p*, space occupied by the glass and drawing paper.

Having acquired a knowledge of the nature of disease, he *is next* introduced to the means of combating it. He is shown that therapy includes drugs, dietetics, and surgical, psychic and social factors, and the mastering of the data of this vast armamentarium is a work truly *prodigious*. And thus far, the work has still been wholly a collection of data. Now comes the work of the philosophical chairs whose duty it is to present the subject of diagnosis; to show the correlations of the data of pathology and the data of therapy, and to crown all with the training of the professional judgment. The art of diagnosis is necessary because diseases do not come labeled. Diagnosis is a purely logical procedure. In each of the great departments of human thought, the logic of that department has peculiarities of its own, and so the logic of medicine is peculiar to it. Certain methods of reasoning are especially fruitful of results; certain fallacies are apt to recur frequently, and to use the one and avoid the other requires training. It is convenient to group the peculiarities of medical reasoning under the term "medical mode of thought." I can not here undertake to prove the truth of these latter assertions, but am content to refer any who question them to Bain, who in his chapter on the Logic of Medicine, in his "Inductive Logic," has fully and conclusively set the matter forth.

Among the more recent innovations in medical education upon which divergence of opinion and practice exists, is that of completely separating the teaching of the basic sciences, usually presented *in the first two* years of work, from the remainder of the instruction. Closely associated with this, is the tendency to offer to undergraduate medical students, opportunities for original research in these basic sciences. It has been said that, "When a physician makes a diagnosis he follows precisely those methods of observation, comparison and experiment which are employed in original research." Granting the verbal accuracy of the language, the statement is still misleading. The statement is in principle true of every investigation from original research to common gossip. It is, therefore, too broad to be of any peculiar utility. It is misleading *in that it implies that in original* research, and in diagnosis the methods of observation, comparison, and experiment are identical, and that the fulness of diagnosis, conclusion, and that the end of research, truth, more general than specific, are both reached by similar acts of judgment. So long as the logic of medicine has its own peculiarities, its methods of observation, comparison and experiment can not be absolutely identical with those of *anything* else, not even with those of one of its basic *sciences. But it is in the latter* parts of the two methods of *reasoning that* the great differences occur. I shall endeavor to make this appear by analyzing the two *processes* of original research and medical diagnosis. Original *research* has for its object the determining of new truths of a more or less general character. The new truth *may first* exist merely as a creature of the imagination, an hypothesis. This hypothesis is then subjected to *verification* by experiment and observation. If *the experiments* and observations confirm *the hypothesis* so fully that no *alternative or modifying* hypothesis can be conceived of to limit the original hypothesis, that original hypothesis is accepted as a truth, but not until it is so *completely verified*. New truths may also be derived by direct comparison of data established by observation and experiment. A characteristic feature in research work is deliberation. The *supposed* new truth waits for its announcement, *certainly* at least for its acceptance, until a sufficiency of data has been collected to establish it beyond doubt. As Huxley[1] says: "There is *one* guiding rule by which a man may always find this path [to truth] and keep himself from straying when he has found it. This *golden rule* is—give unqualified *assent to no propositions* but those the *truth* of which is so clear and distinct that they can not be doubted." Any so-called research less critical is unworthy of the name. It follows, therefore, that a research must often wait, and wait indefinitely for the collection of the necessary data to round it out, and bring forth a just conclusion. A so-called conclusion to an incomplete research, hedged with the adjective "tentative" is no conclusion at all; it carries no responsibility. The time element therefore is an important feature in original research, and the time may be indefinitely prolonged. In medical diagnosis the problem is to determine the state of affairs in a given patient. The particular methods of obtaining the data are those peculiar to medical investigation. When obtained these data are often insufficient to afford a positive basis for any conclusion. Occasionally, conditions are such that time may be spent waiting for additional data, but much more frequently the decision must be made at once, for action is demanded, and that action is determined by the decision as to the meaning of the data. Frequently, it is quite impossible to obtain a sufficiency of data, because original research in correlated branches of knowledge has not yet formulated laws governing the conditions. But nevertheless a conclusion must be made, for action is necessary. The time element is here important also but the time must be short, or life may be the forfeit. It follows from this, therefore, that the tentative conclusion is common in diagnosis, and unlike the tentative conclusion in research, it is one involving great responsibility. Inasmuch then as tentative conclusions must be made in diagnosis, and as it is essential that those diagnoses be as accurate as possible, great care must be exercised in the methods of thought used in reaching these conclusions. To this end we have recourse to the Logic of Medicine, which has become the logic of medicine, precisely because experience has shown that it is the most potent in reaching the truth under such circumstances. The "medical mode of thought" therefore ought to be inculcated throughout the whole of the medical student's career. When the diagnosis is made, it must then be compared with the data of therapy, in order that a second conclusion may be reached, and this second conclusion is the one which formulates the specific action to be taken, and in making it, psychic and social factors must be considered as well as the purely medical, and here again the "medical mode of thought," the trained professional judgment, comes into action.

---

[1] On Descartes' "Discourse."

So far as research work trains observation it is good, but powers of observation can be trained equally well on pulse and tongue, facies and feces, as with the aid of balances and microtomes; so far as research work trains the judgment, it trains it in a bad direction for the young medical man. It tends to establish modes of thought which hamper rather than help him at the bedside. For anybody to do research work on problems formulated by some one else is largely child's play and hardly rises above the dignity of ordinary clerical work, while at the same time it tends to inculcate a sense of personal importance which is so far from the truth that it can not but be detrimental to its victim. The clinic is the field for medical thought and action. Resting upon its basic sciences, which are for its purposes tributary and subordinate, medicine has a systematized knowledge of its own, extensive in scope, highly complex, difficult to acquire, and requiring the best efforts of the best intelligences for its highest use. The systematized, truly medical knowledge may be designated by the word clinicism, which is the true science of medicine. The time for the medical man to undertake research work is when his experience has become sufficiently ripe for him to formulate his own problems; then his research work will have some life in it; his problems should be clinical problems, and certainly there are enough of them to satisfy the most varied tastes. The importance of inculcating the medical mode of thought and training professional judgment, is, in my opinion, so great that I would have them meet the student at every turn in his medical college career, from the very day of his entrance, and to this end I would have the teachers of the so-called scientific branches of the curriculum associated, as far as possible, with clinical work, and urge them to put themselves in constant touch with clinical men, that they may impress upon the student the professional bearings of their tributary work. The medical course is short enough now; it is difficult to find time to present all that should be presented to the student, and there is certainly no time to let him stray after strange gods. It is the business of the medical student to receive medical knowledge and to be trained in its use; he is under no obligations to add to the sum total of medical or any other knowledge. To-day an overwhelmingly large percentage of the physicians of the country devote their whole time to the application of medical knowledge to individual patients. It is right that they should. It is what the community expects of them. It will continue to be so in the future. With the few physicians who do research work, it is a side issue, and their real work is this same application of medical knowledge to individual patients. Such medical students as wish to engage in research work should limit themselves to it, and not hamper themselves with practice and they will find that their medical brethren will welcome every contribution of knowledge which they send out. If legislation should be for the benefit of the greatest number, so ought education, and to this end the medical college should keep its prime duty ever before it. It is the function of the physician to practice medicine; it is, therefore, the duty of the medical college to train him for that work. Let us make physicians rather than scientists.

NECESSITY OF A PRACTICAL KNOWLEDGE OF DIETETICS, HYDROTHERAPY AND PHYSICO-MECHANICAL THERAPEUTICS.

THE NEED OF ESTABLISHING COURSES OF INSTRUCTION IN THESE SUBJECTS IN OUR MEDICAL SCHOOLS.

FENTON B. TURCK, M.D.

CHICAGO.

Until very recently the profession has for the most part relied upon the administration of drugs for the alleviation and cure of disease—all other means except surgery being left to the abuse of charlatans and quacks. But it is the sign of the present state of scientific development, that the attention of the thoughtful has been called to the effects that may be obtained by agents not emphasized in books on materia medica, therapeutics, or in the pharmacopeia. The value of general hygienic conditions and of surroundings; the necessity of proper and systematic bodily exercise; the curative power obtained through the placing of the patient's mind in the proper psychological attitude; the importance of the use of a diet suitable to the case and to the individual; the bearing that heat and cold may have upon the bodily functions in general, and especially on the different parts of the human organism when intelligently applied; the efficacy of massage and electrical therapeutics—

all these are now recognized as forming important elements in the alleviation and cure of many pathologic conditions.

Since these means form so vital a part as therapeutic agents, it would seem that the time has come to consider the urgent necessity for the systematic teaching of their principles and the intelligent application of the most important and neglected of them. Broadly speaking, these would appear to be the subjects of dietetics, hydrotherapy, and physico-mechanical therapeutics.

The reasons for viewing these subjects mentioned as so extremely important are, that, in the first subject—dietetics—the question is involved of how life is sustained and nourished, with the laws that govern such a process—a fundamental proposition; in the second subject—hydrotherapy—the consideration is required of how the body and its parts are affected by three of Nature's most common and potent agencies, to whose modification we, and every form of matter, are more or less subject at all times—viz., heat, cold and water—the latter modified in temperature from the normal to one extreme or the other; in the third subject—physico-mechanical—is contained a pointed reference to the broad and universal truth, that the thing which has ceased to use or perform its functions has begun to die, that the exercise of function is one of the most potent factors in maintaining life, and that, if the individual is not able to maintain such exercise of himself, the question of some outward agency may help him to accomplish it, or that such agency may obtain for him in some way the physiologic results of such exercise, is a consideration the importance of which can not be overestimated.

In order to learn whether the necessity for the teaching of dietetics, hydrotherapy and physico-mechanical therapeutics was realized, and whether the need of such instruction was being met, the writer sent letters to the various medical schools and colleges throughout the United States, asking each for its bulletin, catalogue, or yearly announcement. Most of the institutions written to immediately responded. Upon examining the printed curricula of the different schools, it was found that the three subjects above referred to were for the most part given but small space in the general scheme of study, and in not a few institutions were entirely omitted from the course.

To get the voice of competent opinion from medical teachers (after learning the conditions as they were at the schools), the writer prepared a second letter, which he sent to the dean of each institution in the United States. The letter was as follows:

> Dear Doctor:—I would like to obtain your opinion of the importance of teaching medical students three subjects now neglected in medical education, viz.: 1, Hydrotherapy; 2, Medical Gymnastics and Massage; 3, Dietetics.
>
> The practical demonstration method of teaching these branches would not seem to burden the student, especially Medical Gymnastics, which would rather be a physical benefit and a mental rest.
>
> Hydrotherapy and other physical methods of treatment seem now to be almost a necessity in the armamenture of modern therapeutics. This branch and Dietetics are left to the nurse or to the caprice of the patient. A thorough and practical knowledge should belong to every physician. The practical and scientific knowledge of these three branches would put a check upon quackery and ignorance.
>
> Kindly answer enclosed questions, and oblige.

Accompanying this letter was a blank on which were printed five questions, as below. Over half of the representatives of the schools written to returned the blanks originally mailed, with complete answers written upon them. These replies fairly represent the consensus of opinion of the colleges and medical schools of the country, as they came from institutions of different types, both large and small. The questions were:

1. Are you in favor of including the subject hydrotherapy in the curriculum of medical schools?
2. If so, are you in favor of teaching by practical demonstrations in the hospital and dispensary, or by the didactic method?
3. Are you in favor of teaching medical students practical medical gymnastics and massage?
4. Do you consider the study of practical dietetics a necessary part of the student's education? The character and preparation of food, cooking, etc.? The physiology, pathology, and therapeutics of dietetics?
5. What would you suggest as the most practical method of teaching this branch? Practical demonstration or otherwise?

To the first question, out of 59 answering, 1 replied: "Not as an undergraduate study;" 2 replied: "No;" 39 replied in unqualified terms: "Yes;" and the balance answered that hydrotherapy was already being taught as a branch of general therapeutics, or that they advocated its so being taught, but not as a special subject by itself. In all of these replies, save two, the prime importance of the serious consideration of hydrotherapy is fully recognized.

To the second question, out of the same number of letters received, 3 gave no answer; 1 replied: "No;" 1 advocated the didactic method; 16 advised practical demonstration; and 38 suggested both practical and didactic methods as likely to afford the best results.

To the third question, 1 gave no answer; 1 was undecided, not having given the subject sufficient study; 1 replied: "Yes; not under these names, however, but as a sub-topic of general therapeutics;" 1 answered: "Desirable, but doubtful whether time is sufficient;" 2 said: "To a limited extent;" 46 wrote unqualifiedly, "Yes;" and 7 answered, "No."

To question No. 4, 1 gave no answer; 1, "In a limited way;" 1, "Business of the nurse," 1, "Not as a separate course;" 1, "Desirable, but can't see how it can be accomplished;" 1, "Questionable whether it can be introduced into four years' curriculum;" 1, "Character and preparation of food, yes; cooking, no;" 3, unqualifiedly, "No;" 49, unqualifiedly, "Yes."

To the fifth question, 16 made no reply; 3 said that dietetics is already sufficiently taught by didactic and practical methods in their institutions; 4 advocated lectures and didactic methods; and 36 preferred practical demonstration in the hospital, coupled with theoretical teaching.

On reviewing and analyzing these various answers, it will be seen that there is an overwhelming majority of those who favor the establishment of some method by which the subjects we are considering may be more carefully and systematically taught; and that the greater number of those who have replied to the questions propounded lay very great stress on the importance of teaching by practical and illustrative methods.

Together with these answers written on the printed slips, and categorically replied to, many letters were received, giving the personal opinion of the writers as teachers and professors. The following are included here, as showing that not only are dietetics, hydrotherapy and physico-mechanical therapeutics not sufficiently taught, but that there is a genuine and urgent demand on the part of trained medical educators for placing these branches in the curriculum of the schools:

David Streett, Dean of the Baltimore Medical College, Baltimore, Md., says:

> . . . There can be no question about the importance of teaching Hydrotherapy; indeed, such has been done a number of years, its importance in the medical curriculum growing each year; and of Dietetics there are few subjects of more intrinsic importance to the practitioner, as well as to the surgeon. As to Medical Gymnastics and Massage, I think they are less important than Hydrotherapy and Dietetics; still they eminently deserve a place in our medical curriculum, provided there be found time for their teaching. . . . I regret to state, in my judgment sufficient importance has not been attached to the thorough knowledge of these two subjects.

Victor C. Vaughan, Dean of the University of Michigan, favors instruction in these three subjects, and says:

> I know I talk three hours a week for three months on this subject, and give them a good grounding in the scientific principles of Dietetics. . . As to Hydrotherapy, our students get considerable instruction along this line. . . . We also give considerable instruction in Medical Gymnastics and Massage. . . .

One correspondent, Dr. A. F. Jonas, Dean of the Omaha Medical College, and President of the Western Surgical and Gynecological Association, writes:

> . . . I feel that the three subjects mentioned should occupy a first rank in our therapeutics; but, for some unknown reason, they have been neglected by our schools the world over. It is in the use of these particularly that "quackery" has obtained a large part of its capital stock. I am sure that if these subjects will be scientifically taught and properly applied by the profession, we will have added to our armamentarium most important factors for good.

H. G. Brainard, Dean of the College of Medicine, University of Southern California, Los Angeles, says:

> . . . I feel very strongly on the point that some systematic teaching should be given in the medical college in regard to the use of Hydrotherapy, and in regard to Dietetics. I do not feel so sure about the question of Medical Gymnastics and Massage. While I think that a more thorough knowledge of these subjects would be beneficial, it does not seem so imperative as a more thorough knowledge of Hydrotherapy and Dietetics. Though I presume that a thorough knowledge of gymnastic manipulations and massage would drive osteopathy out of the field.

Dr. E. O. Sisson, Dean of the College of Physicians and Surgeons, Keokuk, Iowa, writes:

> I hasten to give affirmative answers to the questions you have propounded, for I believe you have struck the keynote, and that the introduction of such teaching will mark an epoch in medical science.
>
> The only school that I know of that carries out practical instruction in Dietetics is the Medical Department of the Minnesota State University, and the professor of that department told me that it was not compulsory there. They have a very complete laboratory, fitted with gas ranges, and the necessary cooking appliances, and each student prepares his own dishes.
>
> Medical Gymnastics, as you say, would not burden the student, but would rather be a physical benefit, and a mental rest.
>
> Hydrotherapy, although taught to a greater or less extent in most schools, it is very seldom that a practical demonstration is given of it.
>
> I heartily agree with your statement that "a practical and scientific knowledge of these three branches would put a check upon quackery and ignorance."
>
> We are dealing with subjects here, the value of which thinking people must realize sooner or later, and the physician by an intelligent practice of such will do a great deal towards doing away with the superstition and mystery with which the charlatan has always loved to surround the practice of medicine.
>
> In my lectures on Hygiene to the medical students, I try to impress upon them the value of these subjects, but as my work is necessarily all didactic I fear they fail to take the interest that they should, and therefore they do not realize the importance of the subjects. In my lectures to the nurses, where there is more opportunity for practical demonstration, I believe that more is gained.
>
> I certainly wish you success in your investigation, and hope that your work will be productive of much good.

Dr. S. W. Williston, Dean of the School of Medicine, University of Kansas, says:

> I believe that all these subjects should find a place in medical instruction, and, of course, wherever taught, they should be, so far as possible, taught by the laboratory method, that is, by actual doing or seeing done.

Dr. Alfred C. Wood, of the University of Pennsylvania, Philadelphia, writes:

> Of course, I appreciate the difficulty of having hours set apart for these subjects in a curriculum already so full; at the same time, in my opinion the necessary readjustment should be made to admit these subjects.

Besides reports from the medical schools the writer has received similar complete reports from many of the editors of our medical journals, and also from the president and other officers of the state medical societies, offering their views and comments as to the importance of more practical instruction in these subjects.

Lack of space prevents the publication of these reports here.

In order intelligently to approach the question we are considering, and that practical suggestions of value may be made, it will be well to review what consideration is generally being given to hydrotherapy, dietetics and physico-mechanical therapeutics, and how they are being taught.

From the replies we have received, it would seem that small part of the attention due these subjects is being paid them. The physiology of dietetics is usually embodied as a part of the lectures under the chair of physiology in the first year of the student's course. In the majority of the colleges the subject is not made plain by any means of actual demonstration; while the therapeutics of dietetics is taught, only incidentally, in connection with the subject of general medicine, usually in the fourth year. The student graduates, with superficial instruction in, or practically ignorant of, the application of dietetics in health or disease. A large number—nay, the larger number of the graduates of our schools—afford examples of the deficiency of knowledge of the composition of foods, the chemical changes taking place in cooking, the digestibility and the absorbability of the various forms of nutriment. And from this it also follows that there is a woeful lack of the understanding of the therapeutics of dietetics, which latter involves the practical application of the facts and laws of this subject in the treatment of different diseases.

The very important subject of hydrotherapy, which comprises the application of water internally and externally, from solid to fluid and vapor—from ice to steam—depending for the result upon the judicious adaptation of its mechanical and thermal influences, is being neglected also. This branch of therapeutics it is customary to teach from the chair of general therapeutics; in most cases, merely by didactic methods. As a result.

the student has neither a definite knowledge of the physiologic action of water, which can only be gained by practical experience, nor the understanding of its intelligent application in diseased conditions. The effect of heat in all its variations of temperature, with such a wide range of therapeutic uses, is of both scientific and clinical importance.

Physico-mechanical therapeutics, which embraces medical gymnastics and massage, with some forms of the application of electricity, is not less important than the other two subjects, and what may be said in regard to the lack of proper training and instruction in these two may apply to the other.

Practical dietetics can not be universally introduced without the free use of hospitals equipped with dietetic kitchens; but in schools where such hospital facilities are at hand, a section of the class could take its turn under a competent instructor, certain hours in the day, during the week, in acquiring the accurate knowledge of the preparation of foods and their proper administration in the cases being treated in the institution. The effects could then be readily appreciated by actual demonstration; and thus another and most important element would be added to the skill of the future practitioner.

No objection, however, can be urged against the illustrative method of teaching hydrotherapy and physico-mechanical therapeutics. Every school is equipped with college dispensaries. All that is needed is to arrange a room, or suite of rooms, equipped with the necessary appliances for the application of water in various forms, and with the different mechanical apparatus to be used. These arrangements may be as elaborate or simple as the school can afford. A separate, or adjoining room may be equipped for placing the patient where he may obtain the benefits of the various forms of physico-mechanical therapeutics. In the customary division of students into sections, for the different dispensary classes, a certain number can readily be allotted to each of the rooms above mentioned, just as they are assigned now to the rooms for instruction in surgery, gynecology, nervous diseases, general medicine, dermatology, etc. The clinical material may come direct, or may be referred from the other departments of the institution. Students will gain more exact knowledge by being called upon to assist the instructor in his daily work; and more patients can be treated when the students are turned into assistants—which is a double gain. This method would not trespass on the time allotted to other work, or unduly press upon the strength of the student; and therefore it would appear to be perfectly feasible. As the value and practicability of the subjects we have been considering become further recognized by the faculties of our medical schools, special elective courses may be established, under trained instructors, in order to give the student theoretical and practical teaching combined. The writer has found in his own experience in teaching that these practical methods are easier for the student. They give him an opportunity to learn more accurately by actual observation and experience, associating the clinical importance of the case with the therapeutic measures used.

It will thus be seen that such observation and experience will help the student to comprehend the pathologic condition of the patient—whether a medical or surgical case, and he is better enabled to grasp the clinical and scientific phenomena presented to his mind. The significance of medical teaching will become real, better understood and more easily remembered. The accumulated facts obtained from didactic teaching will also thus be better utilized, and the mind stimulated for further investigation and study.

364 Dearborn Avenue.

THE SEMINAR METHOD IN MEDICAL TEACHING.

BAYARD HOLMES, M.D.
Professor of Surgery and Clinical Surgery in the University of Illinois.
CHICAGO.

The present is a time of great change in methods, as well as in the principles of pedagogy in our medical schools. The extent of medical science is so great that no individual can expect to be master of the whole field. The duration of the course preparatory to the practice of medicine is now long enough, and the preliminary education is now thorough enough to allow the best methods of study to be used. For a certain part of the medical curriculum there is no plan of teaching which promises so much as the seminar.

In previous publications[1] I have called attention to my own efforts in this direction. It is my purpose here to make another plea for the more general adoption of the seminar, in teaching almost any topic of interest to the student.

In order that we may understand each other, let me say that the seminar is a method in which each member of the class does independent laboratory, clinical or library work on a subtopic of general interest to the class as a whole, this subtopic chosen by the student or assigned by the teacher. The seminar is a meeting of the students and the teacher to hear, question, criticise and discuss the work of individuals. When the seminar meets for the first time the teacher presents the general subject in the form of a lecture, in the course of which the whole topic is outlined and interesting questions are put forward. From these questions and the outline, and from a knowledge of the individual members of the class, the assignments of subtopics are made. A student takes his assignment and studies up the question, and at the next or some subsequent meeting of the seminar, he presents to the class in such a manner as the case requires, the results of his study. This time it may be an analysis and blackboard talk, the next time a carefully-written abstract, then again a microscopic demonstration and written paper, or later and more complete than any of these, a finished thesis. During the presentation the student who has the floor is in the position of the teacher. The teacher for the moment becomes one of the students. At any moment during the presentation questions may be asked or explanation required. At the end criticsms are to be expected. Such exercises, like laboratory investigation, are time-consuming. The student should have not less than one-half his daily study time for a seminar of two hours a week. The seminar class should not exceed 20 students, selected by their interest in a topic or in the teacher. The management of larger classes is limited to unusual teachers and special topics and methods of procedure. In a very limited field I have used the seminar with a class of 150 students.

The seminar presupposes an elective course. In no other way can the student have time for the exhaustive study of a limited number of subjects. The student will, however, be bound to learn in the course of this study most of the general information which lectures and text-book study is intended to teach. The seminar requires an open library of current and standard medical literature and an ability on the part of the student to make economical use of it. The library must be open during all reasonable study hours, e. g., from 8 a. m. to 10 p. m., and it must be thoroughly catalogued even down to the monographs and important articles in the serials. It will often, in the course of a study, be necessary to get material from the Surgeon General's Library and even to make purchases, and provision should be made for these contingencies so that there will be no paralyzing delay. The laboratories, museums, collections, clinics and other equipment of the college must be at ready and unobstructed, even helpful, disposal of the student. If the student has for his topic the appearance of fat necrosis in gallstone disease, he may require not only the literature from the library, specimens from the museum and laboratory, but he may need to undertake considerable correspondence with pathologists and surgeons, and even wait for autopsies or operation specimens.

---

[1] Holmes, Bayard: "The Seminary Method in Teaching Surgery." The Journal A. M. A., Aug. 8, 1896, *et seq.*

The seminar is certainly a poor method at the beginning for the bottle-fed incompetents of our compulsory, graded medical course, but many of them even grow and thrive under the exercise and liberty of the seminar and in moments of forgetfulness manifest the ardor of enthusiasm. But there are always some in every class who bear with difficulty the straitjacket of a required course and the lockstep of class instruction, and these erratic men are the delight of the seminar. They plunge with fervor into their subject and devour the literature. They seek on the cadaver or at the operation table the positive anatomical knowledge which their topic requires. They leave no stone unturned which promises the least elucidation of the subject, and they present the results of their study to the class in a convincing argument and with a persuasive enthusiasm.

There are, of course, certain conditions which the student must meet. He must have a motive for study based for the most part upon a considerable amount of bedside experience. Unless the student is actually in the position of the physician with the immediate obligation to cure the patient safely, quickly and pleasantly, he does not possess the strongest, truest and surest motive for study. When this motive is lacking it can often be supplied by giving the student the necessary patient, or by taking such a topic as the student has already met in his practice. When all other means fail, the student's own ailments or deformities may secure the necessary interest.

The student must also have such a preliminary literary training as will make his routine work perfect in form and availability. It is necessary sometimes to secure at the beginning a chirography suitable to such accurate and manageable work as this form of study demands. Every page must be written as perfectly as if for the printer. The slipshod penmanship which the ordinary note-taking in our medical schools begets, entirely precludes the idea of good work. The student must, from the first, do all his work neatly, in an orderly manner and completely, so that it may never require revision or correction. It is only by writing a library hand or something approaching it that good literary work of such a technical character as medicine requires can be satisfactorily done.

The student must know how to use the library. Only a rare librarian can put students in the way of using the library independently. The shelves as well as the catalogue should be accessible to students. The stacks should be in alcoves, with tables and writing material handy, so that the student, after his ability to find them and replace them has been established, can easily consult many books without troubling the librarian. The same may be said of the laboratory and museum. In order that the student may master his subject completely he must be able, if the subject requires it, to study the anatomy of the part concerned in a thoroughly equipped anatomic laboratory, in the pathologic laboratory and in the autopsy room. In fact, the seminar method of study presupposes for its fullest utilization a complete co-ordination and co-operation of all the resources of the medical school. Through its best and freest use the student becomes an investigator of the topic in his hand, of the literature of the various aspects of his subject, and incidentally of the history of medicine itself. The student is put or puts himself in the position which he will occupy after he leaves the school when he attempts to study any medical topic suggested by the requirements of his practice.

Last of all, through the seminar, the medical teacher may secure for the profession the careful literary and experimental study of a large and growing number of subjects which he can never have time to follow out by himself, and he may be instrumental in bringing these subjects before the profession through his students' theses. A considerable number of the most valuable contributions to medical literature comes to us now through the theses of applicants for the doctor's degree in foreign universities. The American students are not less talented or diligent. Our teachers are not less devoted. The continuous course which many medical schools are adopting promises that the end of the course shall be punctuated by the return to the discarded thesis. To make the thesis possible or valuable a considerable portion of the curriculum must be conducted on the seminar plan, whether it is called by that name or not.

MEDICAL EDUCATION.*

J. R. JONES, M.D.
WINNIPEG, MANITOBA.

The writer, after considering the several phases of the subject of medical education, registration, etc., as they apply in Canada, said:

PROFESSIONAL EDUCATION.

The medical curriculum has subjects difficult to acquire, worthless as mental gymnastics, useless in practice and speedily forgotten when acquired. The methods of teaching are imperfect and vicious. The student in didactic lectures is not taught—he is over-lectured and under-taught. The lecturer describes rather than demonstrates and instead of making the student follow him step by step in his methods of observation, collecting, comparing, testing, and recording facts and of reasoning thereon, the didactic lecturer leaves them to be learned by being described, forgetful that they can be learned only by being practiced.

The main tendency of the present method of didactic lectures is to give students smatterings of scientific knowledge at the cost of that thorough knowledge of their art which is essential to its successful exercise. In the curriculum there is overlapping of similar subjects in the didactic and clinical courses. The course of didactic lectures should be entirely abolished or radically modified. Teaching should be bedside work, oral and written examinations with comments by the teacher. In analyzing the didactic course, I would like to direct the attention of the Association to several defects and useless waste of time which could be more profitably employed.

---

* Abstract of the Address in Medicine, delivered before the Canadian Medical Association, Winnipeg, August 28.

What use is there for a didactic lecture on descriptive anatomy; a subject which can only be mastered in the dissecting room. Professor McAllister, of Cambridge, states that anatomy being a practical subject can be learned only in the dissecting room. The line of demarcation between descriptive and practical anatomy is arbitrary and fanciful. In a large class in descriptive anatomy, the favored few near the lecturer and the dissected part derive some instruction, but to all the rest the hour is useless and wasted. Persistent work in the dissecting room under the guidance of an experienced demonstrator who will describe, discuss and constantly orally examine the student is the rational and effective method of teaching anatomy.

Another useless subject is Medical Jurisprudence; the interest in it ends after the examination and to the general practitioner the knowledge thus gained is of no practical value. Few men are called upon to give evidence in criminal cases, and when they are the knowledge acquired while at college is either useless, fragmentary or forgotten, and in order to cut a respectable figure in court, we frantically read up Taylor and Reese. All knowledge is useful, but that derived from Medical Jurisprudence is about as practical to the general practitioner as the geography of Timbuctoo or the philosophy of Confucius. The object of medical teaching is to turn out good practitioners.

Another subject as at present taught which is a weariness to the flesh is Sanitary Science. Its pretensions are stupendous; it is supposed to teach everything—land surveying, architecture, organic chemistry, agriculture, plumbing, drainage and civil engineering. The student is crammed with this conglomerate stuff, which he must intelligently reproduce at the annual examination. In Sanitary Science we have a splendid exemplification of the "cram" system and the utter uselessness of the knowledge, the very essence of smattering. . . .

The burden of the medical student of to-day is very great. More attendance at lectures are demanded, more subjects are being wedged into the curriculum. That a conglomerate heap labeled "Materia Medica" might be treated in a bag and baggage fashion. It is impossible to encompass this large mass of dry technical knowledge in the student's course. Materia medica is a mere tax to the memory—the acquisition largely of bare facts being necessary and facts that are neither retained nor applied. Mr. Huxley's views in an address to the students of St. Mary's Hospital are appropriate. He says: "I am quite prepared to admit, and, indeed, I have always had a strong conviction that there is something absolutely preposterous in the volume and bulk to which some of our treatises on materia medica extend, and the enormous quantity of irrelevant matter with which their pages are crammed." What scraps of information can a didactic lecturer impart to his students which they can not readily find in the text-books! An occasional quiz class with specimens of drugs and their preparation should take the place of the systematic lecture; in fact, let pharmacy and therapeutics take its place. . . .

The system of imparting instruction by lectures is a mediæval custom originating when text-books were few, costly and inaccurate. It is a purely traditional system. Now that there are text-books in abundance covering the whole range, and of excellent merit, these lectures should be modified. The chief value of lectures is that the student is obliged to hear a certain quantity of a subject every day whether he likes it or not, while no authority can compel him to work at a text-book except by moral suasion or arguments of a practical character addressed to his self-interest. A restricted number of lectures may be advisable, but the number could be abbreviated with advantage, and confined to the inculcation of principles; removing difficulties and obstacles from the student's path; explaining types and divergencies of disease; giving information not within the pages of a text-book. The time hitherto employed in systematic lectures might be devoted to class examination on previously announced subjects in which the teacher should indulge in questions, explanations, corrections and comments. This is the true education—a drawing-out instead of a pouring-in process. The lecture system reminds one of the daughters of Danaus, whose destiny was to fill pitchers which could hold no water; the students are percolated receptacles of transitory knowledge. . . .

The "Case" method advocated by Mr. Cannon, of Harvard University, in March, 1900, has received the indorsation of many teachers in England and the United States. This method is supposed to supplant the dreary old-fashioned didactic lecture, and is an imitation of the plan adopted in the law department of Harvard. The plan is to secure printed histories of actual cases which perhaps the student may have seen in the hospital. Each student is previously supplied with a printed copy of the history for careful perusal sometime prior to the discussion. The class and teacher meet and discuss the diagnosis, pathology, symptoms and treatment. Text-books and other literature are consulted, and the case is thoroughly thrashed out. The student is learning the judgment of clinical data, the estimation and relative value of the various symptoms, distinguishing between the important and the unimportant, the common features and the more unique. He not only receives but acquires knowledge. The Case method may supplant or supplement the didactic and clinical courses. This plan is no experiment for it has been on successful trial by several professors at Harvard, by Dr. J. White, of Philadelphia, and Dr. R. E. Riggs, of the University of Minnesota. Possibly I may be prejudiced, but from personal experience I favor the English system of clinical clerkships and dressersships as the most feasible, practical and thorough for the development of medical teaching. It embraces all the advantages claimed by the advocates of the "Case System" and the sectional plan. Moreover, the student is brought into direct contact with the patient for whose history he is responsible. By this method the medical student is trained to habits of minute, careful methodized observation and registration of the phenomena of disease. The student observes his cases from the incipient stage to either recovery or the postmortem room, to the verification or otherwise of his daily recorded observations. Upon this solid foundation of actual personal experience, he builds to fit himself for life's battle.

Malarial Cases Must Be Reported.—Private physicians, public institutions, hospitals and asylums of New York City, are required to report all cases of malarial fever that come under their observation to the Board of Health. At a recent meeting of the board the following resolutions were adopted: Whereas, Recent investigations have shown that malarial fever is an infectious disease and can be largely prevented by the adoption of simple precautions, and Whereas, It is the desire of the Department of Health to prevent the extension of malarial fever, which now exists in some of the boroughs, to the other boroughs, and to restrict its prevalence in those boroughs where it already exists; Resolved, That all public institutions, hospitals, homes, asylums, etc., be required to report all cases of malarial fever which come under their observation, giving the name, age, sex, occupation and present address of the patient, and also information as to whether the attack is a primary infection or a relapse, and the address where the disease was probably contracted. Resolved, That all physicians in the city of New York be requested to furnish similar information in regard to patients suffering from malarial fever under their care. Resolved, That the circulars of information of the Department of Health regarding the causation and prevention of malarial fever be mailed to the addresses in which malarial infection has apparently been contracted, and also to the addresses from which the cases are reported, when these are different. Resolved, That postal cards for furnishing the required data be prepared and forwarded to institutions and physicians for reporting the cases of malarial fever which come under their observation, as is done in other infectious diseases.

MEDICAL SCHOOLS IN THE UNITED STATES.

Below is given a brief description of every college in the United States that is legally chartered to confer the M. D. degree and whose diploma is recognized by at least one state licensing board. The list includes the sectarian as well as the regular colleges, as their graduates are physicians in the eyes of the law. The order in which the colleges are placed is according to date of organization; grouped in cities. The information given is obtained, as a rule, from the catalogues.

ALABAMA.

Alabama, population 1,828,697, has two medical colleges, the Medical College of Alabama and the Birmingham Medical College.

Mobile.

Medical College of Alabama.—This is the medical department of the University of Alabama, and was organized in 1859. It is located in Mobile, a city of 38,469 inhabitants. The City Hospital, under the management of the Sisters of Charity, furnishes free clinical material. The faculty consists of 9 professors and 17 lecturers, 26 in all. It is well equipped with buildings, laboratories, dispensary, etc. Its requirements for admission are those of the Southern Medical College Association. The course of study is graded and covers four years of six months each, but students entering on medical college work prior to the session beginning in 1899 may be graduated in three years. The total fees for each of the first three years is $100; for the fourth year, $125. Board and lodging, $3.50 to $5 per week. The Dean is Dr. George E. Ketchum, Mobile, Ala. Total registration, 1900-1901, 130; number of graduates, 38. The thirty-sixth session will begin on Oct. 8, 1901, and will close April, 1902.

Birmingham.

Birmingham Medical College.—This school was incorporated in 1894 and is situated in Birmingham, a manufacturing town of 38,415. The clinical advantages are good. The Hillman, St. Vincent's, Pratt and County hospitals are accessible to the students. The clinical, histological and pathological laboratories are well equipped. There are 12 professors and 8 lecturers; total teachers, 20. The requirements for admission are those of the Southern College Medical Association. The course of instruction is a graded one and embraces four separate sessions of six months each. Those commencing prior to January, 1899, can graduate after three years. The fees are $75 for each of the first three years and $105 for the fourth. Good board can be obtained at from $12 to $20 per month. The Dean is Dr. B. L. Wyman, 212½ N. 20th St., Birmingham. Number of students registered last session, 77; number of graduates, 15. Next session opens Oct. 2, 1901, and closes April 1, 1902.

ARKANSAS.

Arkansas, population 1,311,564, has one medical college.

Medical Department of the Arkansas University.—This college is located at Little Rock, which has a population of 38,307. It was organized twenty-two years ago as the Arkansas Industrial University Medical Department. It belongs to the Association of American Medical Colleges, having become a member of the Association at its organization, and the requirements for admission are those of that Association. Hospital facilities are furnished by "Logan H. Roots Memorial Hospital," St. Vincent's Infirmary, and Pulaski County Hospital, the latter having a capacity of 200 beds. The teaching body consists of 21, Dr. F. L. French, Little Rock, being Secretary of the faculty. The fees are: Matriculation $5, paid but once; annual fees $58, and graduation $25. Board and lodging costs from $13 to $18 per month. Total number of students at last session, 240; graduates, 20. The next course of lectures begins Oct. 4, 1901, and ends April 11, 1902.

CALIFORNIA.

California, population 1,485,053, has six medical colleges. Five are located in San Francisco, a city of 342,782 inhabitants. They are Cooper Medical College, Medical Department of the University of California, California Medical College, Hahnemann Hospital College, and the College of Physicians and Surgeons. The clinical facilities of San Francisco are good, and board and lodging can be obtained for from $20 to $30 a month. The other, the College of Medicine of the University of Southern California, is situated in Los Angeles, population 102,478. Board and lodging can be obtained in that city for $4 a week and upwards.

San Francisco.

Cooper Medical College.—This school was organized in 1858, though its present name was not adopted until 1882. The faculty consists of 17 professors, and 13 lecturers, demonstrators, etc., 30 in all. Lane Hospital, adjoining the college; the City and County Hospital, containing 464 beds, and the college dispensary furnish clinical material. The requirements for admission are that the applicant must show by certificate or examination sufficient knowledge of English grammar and composition, United States history, geography, arithmetic, elementary physics, Latin grammar and translation, and some knowledge of another modern language or science. After August 15, 1902, the requirements will be raised to equal those of admission to the State University. The college building supplies good laboratory and lecture-room facilities. The curriculum covers a graded course of four years of eight months each. Fees: First year, $115; second, $110; third, $100, and $125 for the fourth year. The Dean is Dr. Henry Gibbons, Jr., 920 Polk St., San Francisco. Total registration for 1900-1 was 167; graduates, 27. The present session opened August 15, 1901, and will close April 29, 1902.

Medical Department University of California.—This department of the State University was organized in 1872, and has a faculty composed of 17 professors, 9 associates and lecturers, 14 instructors and assistants, a total of 40. The City and County Hospital, which admits students of this school not only to the clinics proper, but also to its wards for study, and the college dispensary furnish good clinical material. The senior class is divided into sections of six students each and bedside instruction is given them five days a week. Practical laboratory examinations are required of the students in the laboratories of the hospital, and practical obstetrical demonstrations are given at the bedside. The building is commodious and furnishes good laboratory and lecture-room space. The course covers graded work for four years of eight months each. This school is a member of the Association of American Medical Colleges, and the requirements for admission are those prescribed by that organization. The total fees for the first year are $115; second, $110; third, $100, and $125 for the fourth year. The Dean is Dr. Arnold A. D'Ancona, San Francisco. Total registration for 1900-1 was 164; graduates, 28. The thirtieth session opened August 15, 1901, and will close May 15, 1902.

California Medical College.—Eclectic. This school was organized in 1878. Its faculty includes 14 professors, 8 lecturers and 6 instructors, a total of 28. The clinical material is supplied by the Maclean Hospital. Applicants for admission not holding diploma or certificate are examined. The course has been extended to cover four years of eight months each. Total fees are about $110 for each of the first three years and $40 for the fourth year. The Dean is Dr. D. Maclean, San Francisco. Total registration for 1900-1 was 49; graduates, 10. The next session opens October 7, 1901, and closes May 21, 1902.

Hahnemann Hospital College.—Homeopathic. This was organized in 1884, and has a faculty of 20 professors, and 18 lecturers, instructors, etc., in all 28. The Pacific Homeopathic Polyclinic, the Homeopathic Sanatorium and the San Francisco Nursery for Homeless Children and Marie Kip Orphanage, accommodating respectively 75 children and 120 girls; Fabiola Hospital, and the City and County Hospital furnish clinical material for study. Matriculants must possess a knowledge of English composition, arithmetic, geography, history and Latin, as evidenced by certificate or examination; however, one year after entrance is permitted in which the student may prepare himself. The course includes four years of seven months each. Total fees for the first year, $160, and $75 for each of the other three years. The Dean is Dr. James W. Ward, 606 Sutter St., San Francisco. Total registration for 1900-1 was 40; graduates, 6. The nineteenth session opened May 16, and will close December 12, 1901.

College of Physicians and Surgeons.—This school was organized in 1896, and has a faculty of 10 professors and 26 associates, lecturers, etc., 36 in all. The City and County Hospital, 32 beds of which are available to students of this school for bedside instruction; St. Winifred's Hospital, with 100 beds; City Receiving Hospital, and a sanatorium at San Mateo supply material for clinical instruction. Applicants for matriculation must show an equal amount of work done or pass a satisfactory examination in English, history and government, geography, physics, mathematics and Latin grammar and translation. The college building, recently completed, is large and well supplied with laboratories and lecture rooms. The curriculum embraces four years of six months each. Fees: First year, $90; second, $85; third, $75, and $100 for the fourth year. The Dean is Dr. D. A. Hodgehead, San Francisco. Total registration for 1900-1 was 171; graduates, 38. The next session opens January 2, 1902, and closes June, 1902.

Los Angeles.

College of Medicine, University of Southern California.—This school was organized in 1885, and has a faculty of 21 professors and 10 instructors, etc., 31 in all. The County Hospital, having 200 beds, and a college dispensary furnish clinical material. Applicants for admission are required to pass an examination in English, arithmetic, elementary algebra, physics and Latin equal to one year's work, unless they can show by certificate that they have covered that ground. The building is amply provided with laboratories and lecture rooms. A graded course, covering four years of twenty-six weeks each, is offered. The total fees for the first year are $145; second and third, $130 each, and $40 for the fourth year. The Dean is Dr. H. G. Brainerd, 315 W. Sixth St., Los Angeles. Total registration for 1900-1 was 87; graduates 19. The next session opens October 25, 1901, and closes June, 1902.

COLORADO.

Colorado, with a population of 539,700, has four medical colleges. Three of these are in Denver, which has a population of 133,859: Denver College of Medicine, Gross Medical College and Denver Homeopathic College; the other, the Colorado School of Medicine, is at Boulder. The clinical facilities in Denver available to the three colleges are the Arapahoe County Hospital, which has a capacity of 225 beds; St. Joseph's Hospital, with 200 beds, and St. Luke's Hospital, with 75 beds. The Public Library contains 10,000 volumes on medicine. Board can be obtained in Denver for $5 a week and upwards.

Denver.

Denver College of Medicine.—This is the medical department of the University of Denver, and was organized in 1880. Besides the clinical advantages offered in the above hospitals, the State Home for Dependent Children and the City Contagious Hospital are open to its students. The faculty is made up of 35 professors and 11 lecturers, 46 in all. Its location is central and the buildings are well arranged for laboratory, dispensary and didactic work. The course is graded and covers four years of eight months each. This college is a member of the Association of American Medical Colleges and its requirements for admission are governed by the rules of that Association. Final examinations at the end of each year are held. The fees for the first year are $90; for the next two, $86, and for the fourth year, $101. Dr. Henry Sewall, 23 Eighteenth Ave., is Secretary. Total registration 1900-1, 60; number of graduates, 20. The twenty-first session began Sept. 6, 1901, and will close May, 1902.

Gross Medical College.—This is the medical department of the Rocky Mountain University, and was organized when that institution was founded in 1887. Situated in Denver, the clinical facilities are good, and besides the hospitals used in common by all, St. Anthony's Hospital and the National Jewish Hospital for Consumptives are claimed for its students alone for clinical material. The faculty consists of 28 professors and 16 lecturers, 44 in all. Its buildings are well adapted for didactic, clinical and laboratory teaching. Its requirements for admission are those laid down by the Association of American Medical Colleges, of which this college is a member. The course of study covers a four-year graded course, eight months constituting a year. The total fees for the first two years are $100 each; for the third, $90, and for the fourth year, $75, except to students who matriculated prior to the session of 1900-1 and who have attended their four years at this college, in which case the fourth-year fees are $85. The Secretary is Dr. Robert Levy, California Bldg., Denver. The total registration for 1900-1 was 78; number of graduates, 15. The fifteenth session began Sept. 11, 1901, and will close May, 1902.

Denver Homeopathic College.—This college was organized in 1894. Besides the Arapahoe County Hospital, exclusive privileges for clinical work in the Denver Homeopathic Hospital, the Haven and the Belle Lenox Nursery are claimed for its students. The faculty is made up of 19 professors, and 12 lecturers and instructors, 31 in all. The requirements for admission are, "possession of a diploma from a literary college, university, an academy, a normal or high school; a first grade teacher's certificate, or a previous matriculation at some reputable literary or medical college." The course of study consists of four years of seven months each; monthly examinations are held in each subject. A five-year scholarship may be had for $300, payable in advance, otherwise the tuition is $100 a year; there is a matriculation fee of $5, payable once. The Dean is Dr. James P. Willard, Masonic Temple, Denver. Total registration for 1900-1 was 41; the number of graduates, 5. The eighth session began Sept. 18, 1901, and will close April, 1902.

Boulder.

Colorado School of Medicine.—This is the Medical Department of the University of Colorado, and was opened in 1883. It it situated in Boulder, a town of 6150 inhabitants. The University Hospital, under the control of the state, is equipped to accommodate 40 patients and furnishes free clinical material. Both hospital and dispensary clinics are offered and the sanatorium located in Boulder offers additional advantages in this line. The faculty embraces 15 professors and 10 lecturers and assistants, a total of 25. The laboratories are well equipped and commodious. A separate building is devoted to the study of anatomy and another one is used for medical work exclusively. A complete four-year course of study in a recognized high school, or its equivalent, is required for admission. This school is a member of the Association of American Medical Colleges. The work embraces a graded course of four years of nine months each. The tuition is $50 per year; there are no other fees. The Dean is Dr. Luman M. Griffin, Boulder. Total registration for 1900-1 was 70; graduates, 9. The twentieth session began Sept 9, 1901, and closes June 7, 1902.

CONNECTICUT.

Connecticut has a population of 908,420, and contains one medical college:

Yale Medical School.—This is the department of medicine of Yale University, and is located in New Haven, a good railroad and manufacturing town of 108,027 people. In 1810 a charter was granted for the establishment of this school, and in 1813 it was organized as The Medical Institution of Yale College. In 1879 a new charter changed the name to the one now used, and in 1884 the Connecticut Medical Society, which from the granting of the first charter had taken an active part in its control, released itself from a further responsibility and the University authorities assumed full control. The clinical advantages are embraced under the New Haven Hospital, which contains 150 beds and is the general hospital for New Haven; the Springside Hospital, which is connected with the city almshouse, and the State Hospital for the Insane, which, with its 1800 patients, offers an opportunity for special instruction in insanity in addition to the clinics. Besides these, the New Haven Dispensary, having a staff of 30 physicians, offers material for clinical teaching. The faculty embraces 11 professors, 4 lecturers, 12 instructors, and 16 assistants, a total of 43. The lecture rooms and [illegible] well equipped. Matriculants are admitted [illegible] ded that they have received a degree in A[illegible] present certificates showing that they h[illegible] the subjects of the examination at some college, high school, academy, or preparatory school approved by the faculty, or that they have passed matriculation examinations, equivalent to those required, at some approved professional school. This school is a member of the Association of American Medical Colleges. The course covers a four-year graded curriculum, eight months constituting a school year; the first two years the fundamental branches are studied, the third year is devoted to a systematic teaching of medicine, surgery, obstetrics and pharmacology, and in the fourth year clinical work, with medicine, surgery and the specialties, is presented. The fees are $150 for each of the first three years, and $130 for the fourth year; in the first year there are additional fees amounting to $18, and in the second, $8. Board and lodging in New Haven can be obtained for $4.50 and upwards. The Dean is Dr. Herbert E. Smith, New Haven. During the session of 1900-1 there were 133 matriculants and 18 graduates. The eighty-eighth session opens October 4, 1901, and closes June 26, 1902.

DISTRICT OF COLUMBIA.

Washington, population 278,718, offers to the student of medicine many advantages. The Army Medical Museum, the Museum of Hygiene, the National Museum, together with the libraries in the Surgeon-General's Office, the Toner Medical Library and the Museum of Hygiene, in all over 125,000 volumes upon medicine, opens to the medical student a most profitable field. The clinical advantages offered by the various hospitals are good. Owing to the many boarding houses and hotels, board and lodging can be had at extremely reasonable rates. The medical schools are four, and are as follows:

Medical School of Columbian University.—This school was organized in 1821 as the Medical Department of Columbian College, which in 1873 became Columbian University. Besides University Hospital, under the immediate control of the faculty and giving the students of this school exclusive clinical advantages, the Garfield Hospital, the Children's Hospital, Central Dispensary and Emergency Hospital, the Providence Hospital, the Lutheran Eye and Ear Infirmary, the Episcopal, Columbia and the St. Elizabeth's Hospitals, all permit of abundant opportunity for clinics and clinical material. The faculty is composed of 29 professors, and 23 demonstrators and assistants, 52 in all. The candidates for matriculation are required to conform to the regulations of the Association of American Medical Colleges, of which this school is a member. The equipment and facilities for laboratory, didactic and clinical work are good. The completion of graded work covering the period of four years, eight months to the school year, is required; semi-annual examinations are held. Total fees for each year are $110. The Dean is Dr. E. A. de Schweinitz, 1325 H St. N. W., Washington. For the school year 1900-1 the total registration was 249; the graduates were 26. The eightieth session begins Oct. 7, 1901, and closes May 19, 1902.

Georgetown University School of Medicine.—This is the medical department of Georgetown University and was organized in 1850. The Georgetown University Hospital is under the control of the School of Medicine and affords excellent facilities for clinical teaching and ward classes. Clinics are also held for the benefit of the students in Providence Hospital, containing 300 beds; in the Children's Hospital, the Central Dispensary and Emergency Hospital and the Garfield Hospital. Attendance upon clinical instruction is obligatory in the third and fourth years. The faculty contains 27 professors, and 22 instructors and assistants, a total of 49. The requirements for admission are those of the Association of American Medical Colleges, of which this school is a member. The building is conveniently located, and contains spacious and well-ventilated lecture rooms, laboratories and library; the laboratories are equipped with the most approved instruments and appliances. The complete course of study extends over four terms of eight months each. Examinations are held at the end of each session. The fees for the first year are $100; for the second, $105, and for the last two years, $100 each; a fee is charged for the material used in practical anatomy and operative surgery. The Dean is Dr. George M. Kober, 1600 T St., Washington. The total registration for the session 1900-1 was 123; graduates, 21. The next term opens Sept. 28, 1901, and ends May 31, 1902.

Howard University Medical Department.—*Colored.* This institution was organized in 1867 and "in conformity with the spirit of the organic law of the University, is open to all, without regard to sex or race, who are qualified by good moral character, proper age and suitable education." The removal of any racial distinction has been taken advantage of by colored students, so that it is devoted to them exclusively. The Freedmen's Hospital and Asylum is a general hospital of 300 beds and permits of the study of clinical cases among their own race. The faculty comprises 15 professors, and 10 lecturers and assistants, 25 in all. Matriculants are held to the requirements for admission prescribed by the Association of American Medical Colleges, to which this college belongs. The teaching has been in the past devoted to night classes, but the faculty announces that "it is probable that for the session of 1902-3 the first-year work will be day work almost altogether." Students are required to attend four courses of lectures in separate years of seven months each. The fees for each session are $80, plus $2 per part for dissecting material. Board can be had at the school dining hall for $9 a month, and a room in the dormitory for $15 a term. The Dean is Dr. Robert Reyburn, 714 13th St. N. W., Washington. Total registration for the year 1900-1 was 142; graduates, 19. The thirty-fourth session begins Oct. 1, 1901, and closes May, 1902.

National University Medical Department.—This school was organized in 1884 and has a faculty made up of 30 professors, 1 assistant and 10 demonstrators, a total of 41. Clinical facilities are obtained at the Providence, Garfield and Episcopal Hospitals, the Eastern and Presbyterian Dispensaries and the Home for Incurables. Candidates for admission are held to the requirements laid down by the Association of American Medical Colleges, of which this school is a member. Instruction is given by lectures, recitations, clinical teaching and practical laboratory work. Oral examinations are held each week and final examinations, both oral and written, at the end of each lecture term. The course consists of graded work for four years of eight months each. The total fees for each year are $100, except the first, when an additional fee of $5 is charged. The Dean is Dr. H. H. Barker, 1116 H St. N. W., Washington. Total registration for 1900-1 was 33; graduates, 11. The eighteenth session will begin Oct. 1, 1901, and will extend to May 3, 1902.

GEORGIA.

Georgia, population 2,216,331, has three medical colleges: Medical College of Georgia, located in Augusta; Atlanta College of Physicians and Surgeons, and Georgia College of Eclectic Medicine and Surgery, both in Atlanta.

Augusta.

Medical College of Georgia.—This school was organized as a medical academy in 1829, and in 1873 was made the medical department of the University of Georgia, which relationship it still holds. It is situated in Augusta, a city of 39,441 inhabitants, and its faculty is made up of 15 professors, and 5 assistants, 20 in all. All students *who entered on their first course after Sept. 30,* 1900, must attend four sessions of six months each, those beginning previous to that time are compelled to take only three years' work, but in order to encourage these to take the additional year no tuition is charged them for the fourth year. Applicants for admission must, by examination, certificate or diploma, show that they possess an education equal to that required for second grade teachers in public schools; if they are deficient on examination, however, they are admitted and they may remove the *condition* any time before they appear for graduation. The City Hospital, with 130 beds; Lamar Hospital, with 80; the Polyclinic, and Hospital for Contagious Diseases supply clinical material. Total fees for first two years are $100 each; third year, $90, and $120 for the last year. Board and lodging can be procured *for from $3 to $5* a week. The Dean is Dr. Eugene Foster, Augusta. Total enrolment for 1900-1 was 107; graduates, 30. The seventieth session opens October 1, 1901, and closes April, 1902.

Atlanta.

Atlanta College of Physicians and Surgeons.—This school was formed in 1898 by the consolidation of the Atlanta Medical College, organized in 1854, with the Southern Medical College, organized in 1879. It is situated in Atlanta, an enterprising manufacturing city with a population of 89,872, and has a faculty composed of 14 professors and an adjunct faculty of 17, a total of 31. Clinical facilities are furnished by the Grady Hospital, which is the *general hospital for Atlanta; clinics are free to the graduating* class. First course students are required to "give satisfactory evidence to the faculty of such educational qualifications as will be deemed necessary for the successful prosecution of their medical studies. These requirements will be similar to those of other reputable medical colleges in the country." The course of study covers four years of six months each and is graded; the coming commencement, April, 1902, will graduate the last three-year students. The buildings are large and a new building for practical anatomy has just been added. Fees: Matriculation, paid once, $5; tuition, each year, $100, and $30 for graduation fee. Board and room can be obtained for from $3 to $4 per week. The Dean is Dr. W. S. Kendrick, 71 Washington St., Atlanta. Total registration of students for 1900-1 was 282; graduates, 67. Next session begins October 2, 1901, and closes April 4, 1902.

Georgia College of Eclectic Medicine and Surgery.—This was organized in 1886, and has a faculty of 11 professors and 1 demonstrator. The college dispensary and Grady Hospital furnish clinical material. Applicants for admission must adhere to the requirements established by the National Confederation of Eclectic Colleges, of which this college is a member. The curriculum covers four years of six months each. The Proctor is Dr. Elzie B. Thomas, Atlanta. Total number of students for 1900-1 was 55; graduates, 21. The next session opens Oct. 2, 1901, and closes April 1, 1902.

ILLINOIS.

Illinois, population 4,821,550, has sixteen medical colleges. They are all located in Chicago, a city with 1,698,575 inhabitants, and are as follows: Rush Medical College, Northwestern University Medical School, Hahnemann Medical College, Bennett College of Eclectic Medicine and Surgery, Woman's Medical School, Chicago Homeopathic Medical College, College of Physicians and Surgeons, Hering Medical College, Jenner Medical College, Harvey Medical College, Illinois Medical College, Dunham Medical College, American Medical Missionary College, College of Medicine and Surgery, National Medical University and Chicago Eclectic College. Room and board can be obtained for from $2.50 a week upwards.

Rush Medical College.—This school was founded in 1837, organized in 1843, was the medical department of Lake Forest University from 1887 to 1898, *and in the latter year became affiliated* with the University of Chicago. The faculty is composed of 24 professors, 31 associate and assistant professors, and 59 instructors, etc., a total of 124. Good clinical facilities are furnished ital, caring for about 20,000 patients yearly; with 250 beds; a college dispensary, and an obstetric department. In *addition to* these, extra-mural clinical *courses are offered* at the West Side Hebrew Dispensary, St. Luke's *Hospital*, Illinois Charitable Eye and Ear Infirmary and *Chicago* Isolation Hospital. Bedside instruction is *given. The requirements* for admission are those of admission to the better universities or colleges. For the sessions of 1902 there will be required *a certificate* of admission to the second academic year of an accredited university, and for 1904-5 *to the third year.* By the addition of a recently completed, seven-story building, the facilities for clinical instructions are largely increased. The laboratories and their equipment are unexcelled. The curriculum covers graded work for four years of three quarters each, a quarter being three months. A continuous session is held, but credit *for more than* three quarters can not be obtained in any calendar year. A combined course for six years confers degrees of both Science and Medicine. All freshmen and sophomore studies are given at the University of Chicago. The total regular fees are $157 this year, but it is designed to gradually increase the fees to $200 per year. However, students in continuous attendance, i. e., three quarters in twelve months, may complete their course by paying the fees in vogue when they first enter the college. A matriculation fee of $5 is paid but once, and there are incidentals amounting to from $2 to $5 annually. The Dean is Dr. Frank Billings, 100 State St., Chicago. Total registration 1900-1 was 1055; graduates, 213. The fiscal year begins July 1; final examinations are held at the end of each quarter for those who have completed their work.

Northwestern University Medical School.—This school was organized in 1859 as the medical department of Lind University, became independent as the Chicago Medical College in 1864, and in 1869 assumed its present relation as medical department of Northwestern University. The faculty comprises 30 professors, 10 associates and assistants, and 46 instructors, demonstrators, etc., in all 86. The *newly completed* Wesley Hospital, with 225 beds; Mercy Hospital, *containing* 400 beds; Provident Hospital, *having* 100 beds, and a college free dispensary furnish opportunities for clinical study to students of this college exclusively. St. Luke's, Cook County, and the Chicago Lying-in Hospitals are also open *to them for study.* Applicants for admission must, by diploma, certificate or examination, show possession of the educational acquirements *required to enter* the College of Liberal Arts of Northwestern University. This school is a member of the Association of American Medical Colleges. The laboratory and lecture-room facilities *are ample* and the equipment is good. The course of study covers graded work for four years of thirty-six weeks each. Final examinations are held at the end of each semester. The fees for each year are $135 and a matriculation fee of $5, paid once, is charged. The Dean is Dr. N. S. Davis, Jr., 65 Randolph St., Chicago. The total registration for 1900-1 was 344; graduates, 74. The next session opens Oct. 1, 1901, and closes June 19, 1902.

Hahnemann Medical College and Hospital.—Homeopathic. This was organized in 1851 and has a faculty of 19 professors and 30 associates, lecturers, etc., 49 in all. Hahnemann Hospital and a college dispensary supply clinical material. The requirements for admission are sufficient knowledge of English, arithmetic, geography, algebra, physics, United States history and Latin. A continuous course is held, in which the year is divided into three terms, two of which make up a school year. Four such years are necessary to cover the curriculum. Fees: Matriculation, paid once, $5; each term, $50, and hospital tickets, $5 each for third and fourth years. The Dean is Dr. E. Stillman Bailey, Marshall Field Bldg., Chicago. Total registration, 1900-1, was 175; graduates 51. The fall term began Sept. 9, 1901.

Bennett College of Eclectic Medicine and Surgery.—Eclectic. This school was organized in 1868, and has a faculty of 25 professors and 4 assistants, 29 in all. Bennett Hospital, Cook County and Baptist Hospitals, and a college dispensary supply clinical facilities. Matriculants must present a diploma or "pass a satisfactory examination in conformity with the minimum requirements of the State Board of Health." The course covers four years of twenty-six weeks each. This school is a member of the National Confederation of Eclectic Medical Colleges. Fees for each year are $100, *with a matriculation* fee, paid once, of $5. The Dean is Dr. A. L. Clark, Elgin, Ill. Total registration, 1900-1, was 124; graduates, 37. The thirty-fourth session begins Sept. 24, 1901, and ends May 13, 1902.

Northwestern University Woman's Medical School.—This school was founded in 1870, and in 1892 became a department of *the Northwestern University.* The faculty is made up of 25 professors and 27 assistants, lecturers, etc., a total of 52. The clinical facilities are furnished by Cook County, Wesley and the Woman's Hospitals, the Illinois Charitable Eye and Ear Infirmary and a college dispensary. The requirements for admission are those of admission to Northwestern University College of Liberal Arts. This school is a member of the Association of American Medical Colleges. There is a continuous session, the year being divided into four terms of three months each; three terms constitute a college year, and at least forty-five months must elapse from matriculation to graduation. The fees are $100 each year, with a matriculation fee of $15 for the first year and a diploma fee of $10. The Dean is Dr. Eliza H. Root, Chicago. Total registration, 1900-1, was 72; graduates, 19. The fall session begins Oct. 1, 1901.

Chicago Homeopathic Medical College.—Homeopathic. This was organized in 1876, and has a faculty of 21 professors and 46 adjuncts, lecturers, etc., a total of 67. The Chicago Homeopathic and *Cook County* Hospitals, together with a college dispensary, furnish clinical material. Applicants for admission must show by certificate or examination a sufficient knowledge of English, arithmetic, algebra, physics, *United States history, geography,* botany, and Latin equivalent to a year's study. The course covers four years of seven months each. Total fees are about $110 for each year. The acting Dean is Dr. A. C. Cowperthwaite, Marshall Field Bldg., Chicago. Total registration, 1900-1, was 152; graduates, 48. The next session opens Sept. 24, 1901, and ends *April 22, 1902.*

College of Physicians and Surgeons.—This school was organized in 1882 and in 1896 became the medical department of the University of Illinois. The faculty is composed of 39 professors, 38 adjuncts and clinical professors and 38 instructors, etc., a total of 115. The West Side Hospital, containing 125 beds; Cook County Hospital, and a college dispensary and materniay clinic supply most of the clinical material, but under certain conditions students of this school are admitted to the *following hospitals for clinical study:* Augustana, Baptist, Chicago, Woman's, Samaritan and Alexian Brothers' Hospitals, and the Illinois Eye and Ear Infirmary. Applicants for admission must conform *to the requirements* prescribed by the Association of American Medical Colleges, of which this school is a member. A magnificent building has recently been added to the college, and the laboratory, amphitheater and lecture-room space and equipment is good. *A continuous session* is held and the calendar year is divided into three terms of sixteen weeks each. Two terms constitute a collegiate year and credit for more than that amount of work can not be obtained in any calendar year, except with the permission of the Dean. Four collegiate years are necessary *for graduation*. The fees are $130 each for the first two years, $115 for the third, and $125 for the fourth year. The Dean is Dr. William E. Quine, 103 State St., Chicago. Total registration for 1900-1 was 676; graduates, 164. The next fall term begins Oct. 1, 1901.

Hering Medical College.—Homeopathic. This school was organized in 1892. The faculty comprises 23 professors and 13 associates, lecturers, etc., in all 36. Hering College Hospital, National Temperance and Cook County Hospitals supply clinical facilities. The course covers four years of seven months each. The total fees for a full course are $300 The Dean is Dr. H. C. Allen, 5142 Washington Ave., Chicago. Total registration for 1900-1 was 60; graduates, 12. The tenth session begins Oct. 1, 1901, and ends April 11, 1902.

Jenner Medical College.—This is an evening school, organized in 1892. The faculty consists of 24 professors and 8 assistants, 32 in all. Cook County Hospital and college dispensary supply clinical material. This college conforms to the requirements of the Association of American Medical Colleges. The course covers four years of forty-two weeks each and embraces laboratory, didactic and clinical instruction. The total fees each year are $100, with a $5 matriculation fee, paid but once. The Secretary is Dr. Stuart Johnstone, 34 Washington St., Chicago. Total enrolment for 1900-1 was 101; graduates, 13. The next session begins Sept. 2, 1901, *and ends June 19, 1902.*

Harvey Medical College.—This is a night school and was organized in 1894. The faculty comprises 39 professors and 8 assistants, demonstrators, etc., 47 in all. The college dispensary, having departments for both indoor and outdoor patients, where one evening clinic a week is held, furnish most of the material for clinical study. The requirements for admission are those of the Association of American Medical Colleges. The course covers four years of ten months each. Total fees for the first three years are about $130 each, and for the fourth year $150. The Secretary is Dr. J. Chase Stubbs, Chicago. Total registration for 1900-1 was 270; *graduates*, 17. The eighth session opened Sept. 2, 1901, and closes June 28, 1902.

Illinois Medical College.—This school was organized in 1894 and has a faculty made up of 24 professors and 15 assistants, associates, etc., a total of 39. A college dispensary and Cook County Hospital are available for clinical study. The requirements for admission are based on those of the Association of American Medical Colleges. A continuous course consisting of four terms to the calendar year is offered, two terms of three months each constituting a college year. F[illegible] necessary for graduation, and forty-two [illegible] tween that time and matriculation. Total [illegible] ach year. The Dean is Dr. B. B. Eads, Chi[illegible] for 1900-1 was 202; graduates, 36. The next fall term begins Oct. 1, 1901.

Dunham Medical College.—Homeopathic. This was organized in 1895 and has a faculty of 31 professors and 8 associates and lecturers, in all 39. Cook County Hospital, Garfield Park Sanitarium, St. Anthony's Hospital and a college dispensary supply the clinical facilities. Four years' work of seven months each is required for graduation. The fees are about $110 for each year. The Dean is Dr. James T. Kent, 92 State St., Chicago. Total registration for 1900-1 was 122; graduates, 18. The eleventh session begins Sept. 24, 1901, and ends April 29, 1902.

American Medical Missionary College.—This school was organized in 1895, and has the primal object of educating men and women to act as missionaries and emphasize their religious teachings through their ability to heal the body. The faculty comprises a total of 21 teachers. The didactics and laboratory work, covering the first two years, is carried on at Battle Creek, Mich., and the clinical studies in Chicago. A hospital with 20 beds, in connection wit[illegible] with a college dispensary, containing an [illegible] supply material for practical work. The requirements are based upon those of the Association of American Medical Colleges. The course covers four years of nine months each. Total fees are $120 for each of the four years. The Secretary is Dr E. L. Eggleston, Battle Creek, Mich. Total registration for 1900-1 was 119; graduates, 13. The seventh session opens Sept. 25, 1901, and closes June 24, 1902.

College of Medicine and Surgery.—Physio-Medical. This school was organized in 1896 and has a faculty of 31 teachers. A college dispensary supplies material for clinical work. The course covers four years of seven months each. Fees for the first year, $100; for the second and third, $95 each, and $110 for the fourth. The Dean is Dr. H. P. Nelson, 631 Jackson Blvd., Chicago. Total registration for 1900-1 was 46; graduates, 9. The next session begins Sept. 26, 1901, and ends April 26, 1902.

National Medical University.—This was organized in 1889, and from the catalogue it seems to grant any degree desired, whether medical, dental or osteopathic, and to offer instruction at any time, whether day or night, summer or winter. A teaching force of 61 is shown, and it claims to require of applicants for admission the equivalent of a standard high school education. A four-year course of thirty-nine weeks each is claimed to be necessary for graduation. The total fees are $100 for each year, but "when the fee—$300 for the entire *osteopathic course* is paid in advance, the student may take the entire medical course and obtain the degree, Doctor of Medicine, without any further charge." Its degrees are recognized by the Illinois State Board of Health. Total matriculants for 1900-1 were 144; graduates in March were 6, and in June 6, a total of 12.

Chicago Eclectic College.—The first session of this school will begin September 17. It has not yet been recognized by the Illinois State Board of Health.

INDIANA.

Indiana, population 2,516,462, has five medical colleges. Four are situated in Indianapolis, with 169,164 people: The Physio-Medical College, Central Medical College of Indiana, Central College of Physicians and Surgeons, and the Eclectic Medical College. The clinical facilities of Indianapolis are good and board and lodging can be obtained from $2.50 a week upwards.

The Fort Wayne College of Medicine is situated in Fort Wayne, a railroad and manufacturing town of 45,115 inhabitants. Board and room can be obtained there at an average of $3 a week.

Indianapolis.

Physio-Medical College.—This school was organized in 1873 and has a teaching force of 29. The course has been lengthened to four years of 26 weeks each, beginning with this school year. Total fees for the four years are $65 each. The Secretary is Dr. C. T. Bedford, Indianapolis. Total enrolment, 1900-1, was 34; graduates, 9. The next session begins Oct. 1, 1901, and closes April 2, 1902.

Medical College of Indiana.—This is the medical department of the University of Indianapolis and was organized in 1878. The faculty embraces 25 professors and 32 adjuncts, lecturers, etc., a total of 57. The City Hospital, *containing 200 beds; Indianapolis* Dispensary, Central Hospital for the Insane, with a capacity for 1800 patients; St. Vincent's and the Maternity Hospitals, and a college dispensary provide clinical facilities; the wards in the charity hospitals are open to students of this college for bedside instruction. The laboratory and lecture-room space is ample. This college is a member of the Association of American Medical Colleges and the requirements for admission are those of that organization. The course extends over four years of seven months each. Fees: First and second *years*, $80 each; *third, $75, and* $100 for the fourth year. The Dean is Dr. Henry Jameson, 28 E. Ohio St., Indianapolis. Total enrolment for 1900-1 was 253; graduates, 46. The thirty-second session *opens* September 24, 1901, and closes April 24, 1902.

Central College of Physicians and Surgeons.—This school was organized in 1879, and has a faculty of 22 *professors*, and 21 lecturers, demonstrators, etc., 43 in all. The City Hospital, Central Hospital for the Insane, City Dispensary, and a college dispensary supply material for clinical teaching. Applicants for admission must show educational requirements prescribed by the Association of American Medical Colleges, of which the school is a member. Instruction is by means of laboratory, didactic and clinical teaching, and the equipment is ample. The course of study covers four years of six months each. Fees: First year, $100; second, $110; third, $50, and $75 *for the fourth year*. The Dean is Dr. Samuel E. Earp, Indianapolis. Total registration for 1900-1 was 87; graduates, 23. The *present* session opened September 20, 1901.

Eclectic Medical College.—Eclectic. This school was organized two years ago and claims a teaching force of 22. The requirements for admission claimed are those of the National Confederation of Eclectic Medical Colleges. The catalogue shows a four-year course of six months each. A total of 14 students matriculated for 1900-1.

Fort Wayne.

Fort Wayne College of Medicine.—This school was organized in 1879 and has a faculty of 24 professors, and 7 lecturers and assistants, a total of 31. St. Joseph's Hospital, with a capacity of 350 patients; Hope Hospital, with 200 beds; St. Roche's Hospital, having accommodation for 35 patients; Indiana School for Feeble-Minded Youth and Allen County Orphan Asylum, capable of holding 150 children, supply the clinical facilities. This school is a member of the Association of American Medical Colleges and the requirements *and rules* are *those* of the Association. The curriculum covers four years of six *months each*. The course is practical, supplemented by lectures and laboratory work. The total fees for each year *are* $75, *with an* additional $5 matriculation fee, payable once. The Dean is Dr. C. B. Stemen, 25 Broadway, Fort Wayne. Total number of students registered 1900-1 was 35; graduates, 4. The present session opened September 11, 1901, and closes March 25, 1902.

IOWA.

Iowa, population 2,231,853, contains five medical colleges. They are: College of Medicine of the State University of Iowa, College of Homeopathic Medicine of the State University of Iowa, Iowa College of Physicians and Surgeons, Sioux City College of Medicine, and Keokuk Medical College, College of Physicians and Surgeons.

Iowa City.

College of Medicine of the State University of Iowa.—This is situated in Iowa City, *population* 7987, and was organized as the Medical Department of the State University in 1870. The faculty is made up of 14 professors, 7 lecturers, and 10 demonstrators and assistants, a total of 31. The University Hospital, built in 1897 at a cost of $50,000, contains separate surgical, gynecological, medical, ophthalmological and laryngological operating rooms and furnishes good clinical material. A well-equipped hospital also supplies clinical material. Applicants *for* admission must conform to the requirements of the Association of American Medical Colleges, of which this college is a member. The course of study covers four years of thirty-six weeks each, *embracing* graded laboratory, *didactic and clinical* work. Combined courses leading to more *than* one degree are offered. Total fees for each year is $65. Board and lodging costs from $2.50 *to* $5 per week. The Dean is Dr. William D. Middleton, Iowa City. Total *number* of students registered *for 1900-1* was 272; graduates, 35. The thirty-second course of lectures opened September 19, and will end June 12, 1902.

College of Homeopathic Medicine of the State University of Iowa.—This is a department of the State University and was organized in 1877. The faculty is composed *of 10* professors, and 9 lecturers *and* assistants, a total of 19, but some of these are of the faculty of the College of Medicine. The requirements for admission, and the work, with the exception of that pertaining to homeopathy, are the same as those for the other department. The fees are also the same. The Dean is Dr. Gorge Royal, Iowa City. Total registration for 1900-1 was 59; graduates, 16. The twenty-fifth session began September 19, and will end June 12, 1902.

Des Moines.

The Iowa College of Physicians and Surgeons.—This is the Medical Department of Drake University and is located in Des Moines, a city of 62,139 inhabitants. It was organized in 1882. The faculty contains 17 professors and 6 assistants, a total of 23. Mercy Hospital furnishes clinical material and attendance upon clinics is required the same as upon lectures. The requirements for admission are those determined by the Association of American Medical Colleges, to which this school belongs. Instruction is given by means of lectures, recitations, demonstrations, laboratory work and hospital clinics. The work covers a graded course of four years, of nine months each. Board and lodging can be obtained for $15 a month. The total fees for the first two years are $80 each, and for the last two years, $75 each. The Dean is Dr. Lewis Schooler, Des Moines. The total registration for the year 1900-1 was 78; graduates, 14. The twentieth session began September 18, and will end June 13, 1902.

Sioux City.

Sioux City College of Medicine.—This is located in Sioux City, population 33,111, and was organized in 1891. The faculty is made up of 14 professors and 1 demonstrator, 15 in all. Clinical material is supplied by St. Joseph's, Mercy and Samaritan Hospitals, and a college dispensary. The requirements for admission are those of the Association of American Medical Colleges, of which this college is a member. The system of study embraces a four-year graded course, eight months being a school year. Final examinations are held at the close of each course of instruction. Matriculation fee, paid but once, $5; tuition, each year, $48; hospital fee, $5, and graduating fee, $20. The Dean is Dr. H. A. Wheeler, Sioux City. Total number of students registered 1900-1 was 52; graduates, 5. The twelfth session opened September 10, and will close April 30, 1902.

Keokuk.

Keokuk Medical College, College of Physicians and Surgeons.—In 1849 the College of Physicians and Surgeons, Keokuk, was organized and four years later it became the Medical Department of the University of Iowa, continuing as such until 1870, when the original name was resumed. By the union, in 1899, of this college with the Keokuk Medical College, organized in 1890, the present school under the above name was founded. Situated in Keokuk, a town of 14,641 people, and drawing much from the surrounding country, the clinical material is good. St. Joseph's Hospital, under the charge of the Sisters of St. Francis, is open to the student for study and the clinics held there are large and varied. The faculty is composed of 17 professors and 1 demonstrator, 18 in all. This college is a member of the Association of American Medical Colleges and the requirements for admission are those of that organization. The studies embrace a graded course of four years, seven months to the year. Board and room can be secured for from $2 to $4 per week. The total fees for the first year are $63; for the second and third, $58 each, and $53 for the last year. The Secretary is Dr. Oliver D. Walker, Keokuk. Total registration for 1900-1 was 247; graduates, 51. The next session begins October 1, 1901, and ends April, 1902.

KANSAS.

Kansas, population 1,470,495, has three medical colleges, as follows: School of Medicine of the University of Kansas, located in Lawrence; Kansas Medical College in Topeka, and the College of Physicians and Surgeons, situated in Kansas City.

Lawrence.

School of Medicine of the University of Kansas.—This school does not confer the degree of Doctor of Medicine. It is situated in Lawrence, a town with 10,862 inhabitants, and was organized in 1880 as a department of the University of Kansas. The faculty is composed of 4 professors, 7 associates and assistants, and 7 lecturers, demonstrators, etc., a total of 18. This school is a member of the Association of American Medical Colleges and the requirements for admission are those of that Association. Only the purely scientific subjects are taught, but the work in these is thorough, seventy-two weeks being devoted to the two-year course. The greater part of the work is in the laboratory, with recitations and assigned readings, the lectures being supplementary only. For this reason the equipment and arrangement of the laboratories have been given special attention. A combined course of four years is offered, conferring the degree of Bachelor of Arts in Medicine. The total fees to residents of the state are: For the first year, $60, and for the second, $30; non-residents of the state are required to pay $25 additional for each year. The average cost of board and lodging is $3.75 a week. The Dean is Dr. S. W. Williston, Lawrence. The number of students registered for 1900-1 was 47. The present session began September 11, and will end June 11, 1902.

Topeka.

Kansas Medical College.—This college was organized in 1890 and is situated in Topeka, population 33,608. Its faculty is composed of 27 professors and 6 lecturers and assistants, 33 in all. Good material for both medical and surgical clinics is found in Christ's Hospital, with 100 beds; Riverside Hospital and Dispensary, and Topeka State Hospital; the dispensary at the college also supplies material for class demonstration. The requirements for admission are those prescribed by the Association of American Medical Colleges, of which this school is a member. The college building affords ample laboratory and lecture-room space. The course of study is a graded one covering four years of twenty-six weeks each. Individual instruction is especially aimed at. The total fees for the first two years are $70 each, and $68 each for the last two years. The cost of board and room varies from $2.50 to $4 a week. The Dean is Dr. John E. Minney, Topeka. The total registration for 1900-1 was 98; owing to the change from a three to a four-year course there was no graduating class in 1901. The twelfth session began September 10, and will close March 21, 1902.

Kansas City.

College of Physicians and Surgeons.—This was organized in 1894 as the Medical Department of Kansas City University, and is situated in Kansas City, a city with a population of 51,418. The faculty is made up of 29 professors, 3 lecturers, and 5 demonstrators and assistants, a total of 37. Bethany Hospital, with 60 beds; St. Margaret's Hospital, a college dispensary, and an outdoor obstetric department supplies clinical material. Practical demonstration and bedside teaching is emphasized in the work. It is claimed that the requirements for admission are in accordance with the rules of the Association of American Medical Colleges, but this college is not a member. The course of study is a graded one of four years, seven months each. A scholarship is offered for $175, but taken separately the total fees for the first three years are $60 each, and for the fourth year, $50; a matriculation fee of $5, payable but once, is charged. The Dean is Dr. J. W. May, Topeka. The total registration of students for 1900-1 was 87; graduates, 31. The eighth session opened September 3, 1901, and will close March 26, 1902.

KENTUCKY.

Kentucky, population 2,147,174, has eight medical colleges. They are all situated in Louisville, a growing city of 204,731 inhabitants, and are as follows: University of Louisville Medical Department, Kentucky School of Medicine and Hospital, Louisville Medical College, Hospital College of Medicine, Southwestern Homeopathic Medical College, Kentucky University Medical Department, Louisville National Medical College, and Medical Department of State University. Board and lodging can be obtained in Louisville from $2.50 to $4 per week.

Louisville.

University of Louisville Medical Department.—This school was organized in 1837, under the name, Louisville Medical Institute, and in 1846 it assumed its present title. It has a faculty of 8 professors, 3 clinical professors, 26 lecturers, demonstrators, etc., a total of 37. The University Hospital, City Hospital, St. Mary's and St. Elizabeth's Hospitals, together with the college dispensary, furnish good clinical material. Applicants for admission must show that they possess the educational requirements held by the Association of American Medical Colleges, of which this school is a member. The course covers graded work for four years of six months each. Total fees: First year, $107; second, $122; third, $105, and fourth, $112. The Dean is Dr. J. M. Bodine, Louisville. Total registration for 1900-1 was 157; graduates, 35. The sixty-fifth session begins Sept. 23, 1901, and ends March 31, 1902.

Kentucky School of Medicine and Hospital.—This school was organized in 1850, and has a faculty composed of 10 professors, 10 lecturers and 16 instructors and assistants, a total of 36. The College Hospital, City Hospital and the college dispensary furnish the facilities for clinical study. The student is brought directly into contact with the patient through dispensary and bedside work by dividing the classes into sections. This college is a member of the Association of American Medical Colleges, and the requirements for admission are those of that organization. The laboratories and their equipment are good. The curriculum embraces a four years' course of six months each. The fees for the first two years are $110 each; for the third year, $90, and $80 for the fourth year. The Dean is Dr. W. H. Wathen, 658 Fourth Ave., Louisville. Total number of students registered for 1900-1 was 309; graduates, 43. The next session begins Jan. 2, 1902, and will end July 1, 1902.

Louisville Medical College.—This school was organized in 1869 and has a faculty of 10 professors and 13 instructors and assistants, 23 in all. The City Hospital, College Infirmary and a dispensary offer good clinical facilities. Applicants for admission must show by diploma, certificate or examination that they are sufficiently proficient in English, arithmetic, algebra, physics and such Latin as would be acquired in one year's study. The laboratories and lecture rooms are ample. The course of study covers four years of six months each. The total fees for each year are $100. The Dean is Dr. C. W. Kelly, Louisville. Total registration of students for 1900-1 was 196; graduates, 35. The next session opens Sept. 16, 1901, and closes March, 1902.

Hospital College of Medicine.—This school is the medical department of the Central University of Kentucky and was organized in 1873. The faculty is composed of 9 professors, 9 adjuncts and 23 lecturers, demonstrators, etc., a total of 41. The Gray Street Infirmary, City Hospital and a well-equipped college dispensary present good facilities for clinical study. The requirements for admission are those of the Association of American Medical Colleges. Laboratory work, which is a prominent feature of the course, is thorough and practical. The laboratories and amphitheaters are ample in equipment and capacity, and the hospital advantages give opportunity for personal bedside instruction. The course covers four years of six months each. Total fees for each of first two years, $120; for the third year, $85, and $125 for the fourth year. The Dean is Dr. P. Richard Taylor, Louisville. Total enrolment for 1900-1 was 347; graduates, 52. The twenty-eighth session opens Jan. 1, 1902, and closes June 27, 1902.

Southwestern Homeopathic Medical College.—Homeopathic. This college was organized in 1893 and has a faculty of 18 professors and 13 lecturers and assistants, 31 in all. A college dispensary supplies clinical material. The curriculum covers four years of seven months each. Total fees: First year, $85; second, $80; third, $170, and $65 for the fourth year. The Dean is Dr. A. L. Monroe, Louisville. Total number of students for 1900-1 was 33; graduates, 11. Next session opens Oct. 1, 1901, and closes April 29, 1902.

Kentucky University Medical Department.—This school was organized in 1898 and is the medical department of the Kentucky

University. The faculty is composed of 13 professors, 22 lecturers, demonstrators, etc., 35 in all. Broadway Infirmary, the City Hospital, and a college dispensary furnish clinical material. The requirements for admission are those of the Association of American Medical Colleges, this school being a member of that organization. The buildings provide ample facilities for clinical, laboratory and didactic instruction. The course of study embraces graded work of four years of at least twenty-five weeks each. Total fees: First year, $120; second, $110; third, $95, and $115 for the fourth year. The Dean is Dr. Thomas C. Evans, 419 W. Chestnut St., Louisville. Total number of students registered in 1900-1 was 204; graduates, 20. The next session opens Jan. 1, 1902, and closes June 26, 1902.

Medical Department of State University.—This is a school for colored students organized in 1899. The faculty has 8 professors. The catalogue claims a four-year course of six months each. Total matriculants for 1900-1 were 12.

Louisville National Medical College.—Colored. This was chartered in 1888 and shows a teaching force of 15. The catalogue claims a four-year course, six months to the year; the total fees are about $44 for each year. Total enrolment for 1900-1 was 21; graduates, 4.

LOUISIANA.

Louisiana, having a population of 1,381,625, contains two medical colleges: Medical Department of the Tulane University of Louisiana and New Orleans University. They are both situated in New Orleans, a city of 287,104 people. The cost of room and board is from $10 to $22 a month.

Medical Department of the Tulane University of Louisiana. This school was organized in 1834 as the Medical College of Louisiana, and in 1884 it was incorporated under its present name, but remained the medical department of the State University. The faculty embraces 7 professors, and 17 lecturers, instructors, etc., 24 in all. By acts of legislature the Charity Hospital, with its 900 beds, has been opened to the students of this school for clinical study not only in medicine and surgery, but also in obstetrics and gynecology. In the year 1900 there were 8301 cases treated in the wards of this hospital; these were indoor patients, and, in addition to these, 19,058 outdoor patients were treated in the free dispensary, a department of the hospital. The Milliken Memorial Hospital, with a capacity for 200 children, is also available for study of clinical cases. Bedside instruction is given by the attending physicians to these hospitals, and postmortem examinations are held before the students. This college is a member of the Southern Medical College Association and its requirements for admission are those of that organization. The laboratories are large and well equipped, and the lecture and recitation rooms are ample. The course of study covers four years of six months each. Total fees for the first two years are $135 each, and for the third and fourth, $145 and $165, respectively. The Dean is Dr. Stanford E. Chaille, New Orleans. Total number of students registered for 1900-1 was 390; graduates, 114. The sixty-seventh session begins October 31, 1901, and will close April 30, 1902.

Medical College of New Orleans University.—Colored. This school was organized in 1889 as the Medical Department of New Orleans University. It is devoted to the education of negro students. The faculty is made up of 6 professors and 3 instructors, 9 in all. Clinical material is supplied by the Sarah Goodridge Hospital and by an outdoor clinic. The rules for admission are those of the Association of American Medical Colleges, of which this college is a member. The curriculum covers a graded course of four years, twenty-six weeks each. The laboratories and lecture rooms are ample. Examinations are held monthly. Total fees for the first year are $34; for the second, $37.50; third, $36.50, and $40 for the last year. The Dean is Dr. H. J. Clements, New Orleans. Total enrolment for 1900-1 was 32; graduates, 2. The thirteenth college year began September 3, and will end March 3, 1902.

MAINE.

Maine, population 694,466, has one medical college:

Medical School of Maine.—This is the Medical Department of Bowdoin College and is situated in Brunswick, a town with 5210 inhabitants; it was organized in 1820. The faculty is composed of 13 professors and 5 assistants, 18 in all. The clinical facilities are supplied by the Maine General Hospital. Applicants for admission, unless they possess a diploma, are examined in English, arithmetic, algebra, geometry, United States history, physics, chemistry and Latin. The course covers four years of twenty-six weeks each. The total fees are $120 for the first year; for the second and the third, $110, and $130 for the fourth year. Board and lodging cost from $3 to $5 a week. The Dean is Dr. Alfred Mitchell, Brunswick. Total number of students enrolled for 1900-1 was 90; graduates, 40. The next session opens December 26, 1901, and closes June 26, 1902.

MARYLAND.

Maryland, with a population of 1,188,044, contains eight medical colleges. They are all located in Baltimore, a city with 508,957 inhabitants, and they are as follows: School of Medicine of the University of Maryland, College of Physicians and Surgeons, Baltimore University School of Medicine, Baltimore Medical College, Woman's Medical College, Southern Homeopathic Medical College, Johns Hopkins Medical School, and Maryland Medical College. The Bay View Hospital, having a capacity for 2,000 patients, is open to students for clinical instruction, and furnishes good opportunities for practical demonstrations. Board and lodging can be obtained for from $3 to $5 per week.

School of Medicine of the University of Maryland.—This institution was organized in 1807 as the College of Medicine of Maryland, and in 1812, other faculties having been added, the whole was chartered under the name of the University of Maryland. The faculty is composed of 14 professors, 21 clinical and associate professors, and 24 lecturers, demonstrators, etc., a total of 59. The University Hospital, a part of which is used for a hospital for foreign seamen and another portion for a free city hospital, offers excellent clinical facilities. Besides this, the Presbyterian Eye, Ear and Throat Charity Hospital, in which 10,734 patients were treated in 1900; the Hospital for the Relief of Crippled and Deformed Children, containing 40 beds; the Maternity Hospital, and a college dispensary furnish material for clinical study. This school is a member of the Association of American Medical Colleges, and its requirements for matriculation are those specified by that Association. The laboratories and lecture rooms are ample and well equipped. The fourth-year class, divided into sections, receives special training in practical laboratory work in a well-appointed clinical laboratory. Didactic, laboratory and clinical instructions, special attention being paid to bedside work, make up the system of teaching. The course covers four years of seven months each, and is graded. The total fees for the first two years are $120 each; for the third year, $110, and $140 for the final year. The Dean is Dr. R. Dorsey Coale, Baltimore. The total number of students registered in 1900-1 was 332; graduates, 71. The ninety-fifth session begins Oct. 1, 1901, and will terminate May 1, 1902.

College of Physicians and Surgeons, Baltimore.—This school was organized in 1872, and in 1878 Washington University School of Medicine, established in 1827, was consolidated with it. The faculty embraces 16 professors, 18 associate and clinical professors, and 18 demonstrators and assistants, a total of 52. The clinical facilities, besides those afforded in common with other schools, are supplied by the Baltimore City Hospital, the Hospital for the Colored Race, containing 100 beds; the Nursery and Child's Hospital, with 150 beds; the Maryland Lying-in Asylum, and a college dispensary. The requirements for admission are those established by the Association of American Medical Colleges, of which this school is a member. The work covers a graded course of four years, seven months constituting a year. The laboratories are well lighted and supplied with complete equipment; one important addition is the clinical laboratory for practical work. A skiascopic laboratory is also a recent addition and instructs the students in the use of the *x*-ray apparatus. Total fees for the first three years are $115 each, and $135 for the last year. The Dean is Dr. Thomas Opie, Baltimore. The total number of students registered in 1900-1 was 359, of which number 59 were graduates. The next session opens Oct. 1, 1901, and closes April 15, 1902.

Baltimore Medical College.—This college was organized in 1881, and has a faculty made up of 26 professors, 5 lecturers, 3 associates and 11 demonstrators and assistants, 45 in all. The clinical material is furnished by the Maryland General Hospital, having a capacity of 200 beds; the Maryland Lying-in Hospital, in which 171 deliveries took place in 1900; the Mount Hope Retreat, which presents good opportunity for the study of nervous and mental diseases, and a college dispensary, which, besides the great number of ambulatory patients treated, has an outdoor department that permits of the advanced student taking care of charity cases and carrying out his own treatment. Requirements for admission are those of the Association of American Medical Colleges, to which this college belongs. The college buildings afford ample laboratory, clinical and lecture-room space. Bedside teaching in the hospital wards is carried on in sections and every member of the senior class is required to attend throughout the session. The course of study is graded and covers four years of seven months each. The Dean is Dr. David Streett, Baltimore. The total number of students registered in 1900-1 was 507; graduates, 97. The twenty-first session opens Sept. 26, 1901, and closes April 19, 1901.

Woman's Medical College.—This school was organized in 1882 and has a faculty of 14 professors, 5 adjunct professors, and 9 assistants and lecturers, a total of 28. The Hospital of the Woman's Medical College, Presbyterian Eye, Ear and Throat Charity Hospital, St. Mary's Asylum and a college dispensary furnish clinical material. The college is a member of the Association of American Medical Colleges, [illegible] sion are controlled by the rules of that [illegible] ories and lecture rooms are equipped wit [illegible]. the practical work is emphasized. Eig [illegible] ol year, and the course covers graded work for four years. The total fees for the first three years are $105 each, and $85 for the last year. Total number registered for 1900-1 was 31; graduates, 7. The twentieth session opens Oct. 1, 1901, and closes June 5, 1902.

Baltimore University School of Medicine.—This school was organized in 1884, and has a faculty made up of 12 professors, and 11 lecturers, demonstrators, etc., in all 28. The Baltimore University Hospital, Lying-in Hospital and the clinical material used in common with the other schools, supply the facilities for practical work. In the hospital wards the student is given bedside instruction, and in surgical clinics the students act as assistants in the operations, and are taught to administer anesthetics. The requirements for admission are those of the Association of American Medical Colleges, of which this college is a member. The college dispensary affords much clinical material and the students, under the direction of the physician in charge, make calls and treat patients at their homes. The lecture rooms and laboratories are ample, and the course of instruction, which consists of graded work for four years of six months each, is practical. The total fees for the first two years are $100 each; for the third year, $80, and $110 for the fourth year. The Dean is Dr. Hampson H. Biedler, 119 W. Saratoga St., Baltimore. Total registration for year 1900-1 was 66; graduates, 31. The eighteenth session opens October 1, 1901, and closes April 15, 1902.

Southern Homeopathic Medical College.—Homeopathic. This school was organized in 1890, and has a faculty of 13 professors, 3 associate professors, and 23 lecturers and demonstrators, a total of 39. The clinical facilities are those offered by the Maryland Homeopathic Hospital, which has 55 beds, and the dispensary; the obstetric department also furnishes clinical material. Applicants for matriculation must pass a satisfactory examination in English, arithmetic, geography, history, and Latin, unless they possess satisfactory evidence that they have done a corresponding amount of work. The course covers graded work for four years, seven months to the year. The fees are $105 for the first year, $100 each for the second and third, and $130 for the last year. The Dean is Dr. George T. Shower, 421 Roland Ave., Baltimore. Total registration 1900-1 was 32; graduates, 10. The eleventh session begins September 30, 1901, and ends May 7, 1902.

Johns Hopkins Medical School.—This is the medical department of Johns Hopkins University and was organized in 1893. The faculty comprises 11 professors, 14 clinical and associate professors, 14 lecturers and associates, and 25 instructors and assistants, a total of 64. The Johns Hopkins Hospital and Dispensary furnishes *abundant and varied clinical material*; the lying-in department of the hospital, opened in 1896, is in successful operation. The requirements for admission demand that the applicant either has, (a) completed the chemical-biologic course which leads to the A. B. degree in the University; (b) graduated at an approved college or scientific school, and can furnish evidence of an acquaintance with Latin and a fair reading knowledge of French and German, and such knowledge of physics, chemistry and biology as above indicated. If the candidate is unable to show this, he must pass a satisfactory examination covering this ground. This school is a member of the Association of American Medical Colleges. The anatomic, physiologic, pathologic and clinical laboratories are large, well lighted and well equipped. The buildings are ample and built expressly for the purpose for which they are used. In the method of instruction special emphasis is laid upon practical work in the laboratories, dispensary and in the wards of the hospital. The first two years is devoted to practical work in the laboratories, combined with demonstrations, recitations and lectures, and during the remainder of the course opportunity for the personal study of cases is given. The work covers a graded course of four years, eight months to the year. Final examinations, partly written and partly oral, include practical tests in laboratory and clinical work; the general character of the student's work is closely watched. The charge for tuition is $200 per annum, with no fees unless a microscope is rented: that fee is $5 a year. The Dean is Dr. William H. Howell, 232 W. Lanvale St., Baltimore. Total registration in 1900-1 was 209; graduates, 54. The ninth session begins October 1, 1901, and ends June 15, 1902.

Maryland Medical College.—This school was organized in 1898, and has a faculty of 14 professors, and 11 associates, lecturers, etc., 25 in all. The Franklin Square Hospital and a college dispensary furnish clinical material. The course of study covers three years of eight months each, but after October, 1902, all students matriculating will be compelled to take a four-year course. A matriculation fee of $5 and total laboratory fees for the three years of $45 is charged; the tuition for full course is $65 each year. The Dean is Dr. J. Wm. Funk, Baltimore. Total registration for 1900-1 was 75; graduates, 29. The fourth session begins October 1, 1901, and closes May 15, 1902.

MASSACHUSETTS.

Massachusetts, population 2,805,346, has four medical colleges: Medical School of Harvard University, Boston University School of Medicine, College of Physicians and Surgeons, and Tuft's College Medical School. They are all situated in Boston, a city of 500,892 inhabitants, and enjoy in common the following clinical advantages: The Massachusetts General Hospital, in which during the past year 5086 patients were treated in the wards and 31,003 in the out-patient departments; the Boston City Hospital, where during that time 8719 ward patients and 22,640 out-patients were treated, and the Massachusetts Charitable Eye and Ear Infirmary, which furnished treatment for 22,349 patients during the past year. Library facilities are good. Board and lodging can be obtained for from $5 to $7 per week.

Medical School of Harvard University.—This was organized in 1872 as the Medical Department of Harvard University, and has a faculty composed of 20 professors, 10 associates and assistants, and 1 demonstrator, a total of 31. Besides the clinical advantages mentioned, the Boston Lying-in Hospital, the Boston Dispensary, where 43,918 patients were treated last year; the Infants' Hospital, the Children's Hospital, Long Island Hospital, containing 250 beds, and the Marine Hospital all furnish excellent opportunity to the student for clinical study. Students are also permitted to visit the Free Hospital for Women and Carney Hospital on application to the physicians on duty. Candidates for admission "must present a degree in Arts, Literature, Philosophy or Science from a recognized college or scientific school, with the exception of such persons, of suitable age and attainments, as may be admitted by special vote of the faculty in each case." Each candidate is required to hand in the original note-book in which he recorded the work performed by him in qualitative analysis, and also to pass a written examination in theoretical and descriptive chemistry. If conditioned in chemistry one year is allowed in which to remove the condition. The laboratories and lecture rooms offer ample facilities and the equipment is good; special facilities are open to those desiring to pursue advanced or original work. The course of study covers four years of nine months each; the course is graded, and each correlated group as taken up presents sufficient variety to avoid monotony. A series of written, oral and practical examinations are distributed throughout the course of study. Fees: Matriculation, $5; for the first three years, $200 each, and for the last year, if the three previous years have been taken in this school, $130; total of other fees charged is $22. The Dean is Dr. William L. Richardson, 688 Boylston St., Boston. Total registration for 1900-1 was 591; graduates, 116. The 120th session begins September 26, 1901, and ends June 26, 1902.

Boston University School of Medicine.—Homeopathic. This school was organized in 1873; in 1874 the New England Female Medical College, founded in 1848, was merged into it. The faculty includes 17 professors, 21 associates and lecturers, and 20 instructors and assistants, a total of 58. Clinical material is furnished by the Massachusetts Homeopathic Hospital, containing 225 beds, and a dispensary and maternity hospital. Candidates who have taken their degree in arts, philosophy or science, are not examined; all others are examined in English, Latin, French or German or history, mathematics and physics. The instruction is graded and covers a period of four years, eight months each. Total fees for the first year is $105; for the second and third, $125 each, and for the last year, $155. The Dean is Dr. John P. Sutherland, 295 Commonwealth Ave., Boston, Mass. Total registration for 1900-1 was 127; graduates, 24. The twenty-ninth session opens October 3, 1901, and closes June 6, 1902.

College of Physicians and Surgeons.—This school was organized in 1880, and has a faculty of 24 professors, and 9 lecturers and assistants, a total of 33. Clinical facilities are furnished by the North End Hospital and Dispensary, Union General Hospital, and the city and state institutions. The requirements for admission are those of the Association of American Medical Colleges, of which this school is a member. The course of study covers graded work for four years of eight months each. The total fees for the first year are $100, and for each of the other years about $110, with a graduating fee of $30. The Registrar is Dr. John H. Jackson, 155 Franklin St., Fall River. Total students registered 1900-1 was 127; graduates, 9. The twelfth session begins September 25, 1901, and ends June 26, 1902.

Tufts College Medical School.—This school was organized in 1893 as the Medical Department of Tuft's College. It has a faculty of 16 professors, 6 assistant professors and 31 lecturers, instructors and assistants, a total of 53. Clinical material is furnished by the Boston Dispensary, Cambridge Hospital, St. Elizabeth's Hospital, Carney Hospital and the college dispensary; the student has also the advantages derived from an out-department in connection with the Boston Dispensary. "Graduates of a high school, college or university, and students having certificates of entrance to a college or university, or holding the state of New York Regents' certificate," also certain approved preparatory school graduates, are admitted without examination; all others must pass an examination in English, Latin, physics and mathematics, including arithmetic, elementary algebra and plane geometry. The laboratories and lecture rooms are ample in their equipment and capacity. Teaching is carried on by means of lectures, recitations and practical work in the laboratories and clinics; frequent examinations are held during a course and a final examination on completing the subject. Graded instruction covering four years of eight months each makes up the full course. The total fees is $125 each year; dissecting material is furnished at cost. The Dean is Dr. Harold Williams, 528 Beacon St., Boston, Mass. Total number of students for 1900-1 was 277; graduates, 35. The ninth session begins October 2, 1901, and ends May 28, 1902.

MICHIGAN.

Michigan, population 2,420,982, has seven medical colleges. Two of these, University of Michigan Department of Medicine and Surgery and the Homeopathic College of the University of Michigan, are located at Ann Arbor, a town of 14,509 people. Board and lodging cost from $2.50 to $5 a week. Detroit, a city of 285,704 inhabitants, contains three medical colleges, as follows: Detroit College of Medicine, Detroit Homeopathic College and the Michigan College of Medicine and Surgery. Board and room can be obtained for $3 a week upwards. Grand Rapids Medical College is located in Grand Rapids, population 87,565, and here the cost of room and board is from $3 to $3.50 a week. The other school, Saginaw Medical College, is located in Saginaw, a city having a population of 42,345. Board and lodging can be procured for from $3 to $4.50 a week.

Ann Arbor.

University of Michigan Department of Medicine and Surgery.—This department of the State University was organized in 1850 and has a faculty composed of 12 professors, 15 associates and lecturers, and 39 instructors, assistants, etc., a total of 66. The University Hospital, together with a lying-in department, furnish the clinical facilities. Beginning January 1, 1901, the requirements of admission provide that the applicant either by certificate or examination show a sufficient knowledge of the following: English grammar, rhetoric and composition, United States and general history, algebra, through quadratics, plane and solid geometry and plane trigonometry; physics, biology and chemistry: German or French, and Latin. The laboratories and their equipment are good, and the training in them and in didactic work is thorough. This school is a member of the Association of American Medical Colleges. The curriculum embraces four years of nine months each. A combined course, leading to degrees in both science and medicine in six years, is offered. The total fees for Michigan students for the entire course of four years is about $300, and for others $350. The Dean is Dr. Victor C. Vaughan, Ann Arbor. Total registration for 1900-1 was 563; graduates, 75. The next session begins September 25, and will end June 20, 1902.

Homeopathic College, University of Michigan.—This department of the University was organized in 1875 and has a faculty of 6 professors, 3 assistants and 2 non-resident lecturers; the remainder of the teaching force utilized is that of the other departments of this University. The Homeopathic Hospital, containing 140 beds, furnishes material for clinical teaching. The course covers four years of nine months each. The total fees for Michigan students are about $240 for the four years, and for other students about $295. The Dean is Dr. Walter B. Hinsdale, Ann Arbor. Total enrolment for 1900-1 was 68; graduates, 16. The present session began September 24.

Detroit.

Detroit College of Medicine.—This school was formed in 1885 by the union of Detroit Medical College, organized in 1868.

and the Michigan College of Medicine, established 1880. The faculty embraces 21 professors, 44 lecturers, instructors, etc., and 30 clinical professors, a total of 95. Clinical facilities are offered by the following hospitals: St. Mary's and Harper, each of which contain a free dispensary; Woman's, St. Luke's, the Children's Free Hospital and the House of Providence. This school is a member of the Association of American Medical Colleges and the requirements of admission are those of that organization. The course covers four years of seven months each. The work includes laboratory, didactic and clinical study. Fees: Matriculation, paid once $5; tuition, each term, $60; hospital and laboratory tickets, each $10, and extra senior fees, $40. The Secretary is Dr. H. O. Walker, Detroit. Total enrolment for 1900-1 was 224; graduates, 45. The next session begins September 25, and will close May, 1902.

Michigan College of Medicine and Surgery.—This school was organized in 1888, and has a faculty of 14 professors and 9 assistants, in all 23. Clinical facilities are offered by a college dispensary, the Emergency Hospital and Detroit Eye and Ear Infirmary. This school is a member of the Association of American Medical Colleges and the requirements for admission are those established by that Association. The course covers graded work for four years of seven months each. Fees: For the first two years, $85 each; third year, $70, and $95 for the fourth year. The Dean is Dr. Hal. C. Wyman, 46 W. Adams Ave., Detroit. Total registration for 1900-1 was 75; graduates, 25. The fourteenth session began September 18, and will end April 24, 1902.

Detroit Homeopathic College.—Homeopathic. This was organized in 1899 and has a faculty of 18 professors, and 15 lecturers, assistants, etc., in all 33. Grace Hospital and a college dispensary are available for study of clinical cases. Unless possessing certificate of an equal amount of work completed, applicants for admission will be examined in English, arithmetic, history, geography and elementary Latin. The course embraces work for four years, seven months making a year. Fees: First year, $80; second, $75; third, $65, and $85 for the fourth year. The Dean is Dr. D. A. MacLachlan, Detroit. Total enrolment for 1900-1 was 41; graduates, 4. The next session begins September 25, and will close April 22, 1902.

Grand Rapids.

Grand Rapids Medical College.—This was organized in 1897 as a three-year school, but the catalogue shows that all students matriculating after January 1, 1901, will be compelled to take a four-year course of six months. The faculty is made up of 23 professors and 8 associates, assistants, etc., in all 31. Clinical cases in the U. B. A. Hospital, St. Mary's, Woman's Butterworth Hospitals, and St. John's Orphan Asylum and a college dispensary are available for study. The total fees are in the neighborhood of $65 for each year. The Dean is Dr. E. G. Edwards, Middicomb Bldg., Grand Rapids. Total enrolment for 1900-1 was 47; graduates, 17. Next session opens about October 1, 1901.

Saginaw.

Saginaw Valley Medical College.—This school was organized in 1896, and claims a teaching force of 30. Clinical material is supplied by a college hospital and a college dispensary. The catalogue states that the equivalent education to graduation from a recognized high school is required for admission. The course as shown covers four years of eight months each: Fees: Matriculation, paid once, $5; tuition, each year, $50; laboratory and hospital and dissecting ticket, each $10, and graduation fee, $25. The Secretary is Dr. W. B. Cornell, Saginaw. Total enrolment for 1900-1 was 102; graduates, 24.

MINNESOTA.

Minnesota, population 1,751,394, contains three medical colleges: College of Homeopathic Medicine and Surgery, Hamline University College of Medicine, and College of Medicine and Surgery. They are all situated in Minneapolis, a city with a population of 202,718, and owing to its proximity to St. Paul, the following clinical advantages are available to them: City Hospital, Minneapolis; City Hospital, St. Paul; and St. Luke's and St. Joseph's Hospitals, both in St. Paul. The average cost of board and lodging is $20 a month. An agreement as to requirements for admission has been entered into between the University of Minnesota and Hamline University. They are (a) proof that the candidate has completed work in English composition and rhetoric; history, both ancient and modern; physiology, physics, algebra, geometry, and Latin equal to one year's work, or (b) ability to pass a satisfactory examination in these subjects.

College of Medicine and Surgery.—This is a department of the University of Minnesota and was organized in 1883. Until 1883 its work was only to examine for the degrees of B. M. or M. D., but at that time, with the absorption of the Minnesota Hospital Medical College and the St. Paul Medical College, it was reorganized and its present function assumed. Its faculty is made up of 24 professors, 11 clinical professors, 22 instructors and lecturers, and 20 assistants, a total of 77. Besides the clinical advantages enjoyed in common with the other schools, St. Mary's, St. Barnabas and Asbury Methodist Hospitals, the City and County Hospitals of St. Paul and the St. Paul Dispensary, as well as the college dispensary, all furnish valuable material for clinical study. This college is a member of the Association of American Medical Colleges. The medical buildings, four in number, offer good laboratory and lecture room facilities, and the equipment is all that is needed for thorough instruction. The curriculum covers four years of nine months each and the work is carefully graded. The total fees for each year is $100. The Dean is Dr. Parks Ritchie, Minneapolis. Total number of students registered for 1900-1 was 322; graduates, 60. The next session opens September 23, 1901, and closes June 5, 1902.

Hamline University College of Medicine.—This is the Medical Department of Hamline University, and was organized in 1883. Its faculty is composed of 27 professors, 6 associate and clinical professors, and 12 instructors and assistants, a total of 45. The laboratories and lecture rooms are large, well lighted and supplied with all the necessary equipment. Besides the hospitals mentioned, clinical work is offered to the student in Asbury Methodist Hospital, Barnabas and St. Mary's Hospitals in Minneapolis, Bethesda Hospital in St. Paul, and the college dispensary. This school belongs to the Association of American Medical Colleges. The course of study covers graded work for four years, nine months making a year. Total fees, first year, $87.50; second year, $82.50, and for each of the last two, $75. The Dean is Dr. L. M. Crafts, Minneapolis. Total number of students 1900-1 was 131; graduates, 25. The next session begins September 17, 1901, and ends June 5, 1902.

College of Homeopathic Medicine and Surgery.—This is a department of the University of Minnesota and was organized in 1888. The faculty comprises 17 professors and 5 assistants, 22 in all. The primary branches are taught by the professors of the College of Medicine and Surgery. The course is graded, extending over four years of eight and one-half months each. The total fees for the first two years is $100 each, and $80 each for the last two years. The Dean is Dr. Alonzo P. Williamson, Minneapolis. Total number of students registered in 1900-1 was 26; graduates, 4. The next session opens September 23, 1901, and closes June 5, 1902.

MISSOURI.

Missouri, population of 3,106,665, has fifteen medical colleges. St. Louis, population 575,238, contains six of these, viz., St. Louis College of Physicians and Surgeons, American Medical College, Homeopathic Medical College of Missouri, Marion-Sims Beaumont College of Medicine, Washington University Medical Department, and Barnes Medical College. Board and lodging can be procured for from $3.50 to $5 a week. Kansas City, with 163,752 inhabitants, also has as follows: Kansas City Medical College, University Medical College, the Hahnemann Medical College of Kansas City, Woman's Medical College, Medico-Chirurgical College and Eclectic Medical University. Room and board can be obtained in this city for from $3 to $5 a week. Ensworth Medical College and Central Medical College are located in St. Joseph, population 102,979; board and room can be had for from $2.50 to $5 a week. The Department of Medicine of the University of Missouri is at Columbia, a town of 5651. Board and lodging can be obtained at Columbia for from $2 to $5 a week.

St. Louis.

St. Louis College of Physicians and Surgeons.—This school was organized in 1878, and has a faculty of 21 professors, 19 lecturers, demonstrators, and clinical instructors, and 4 special lecturers, a total of 44. The resources for clinical instruction are Jefferson Hospital, which is open to students of this college only; City Hospital, with 600 beds; French Hospital, having 250 beds; City Insane Asylum; City Poorhouse and the college dispensary. Applicants for admission must show that they are possessed of the requirements prescribed by the Association of American Medical Colleges, of which this college is a member. The laboratory and lecture-room space and the equipment are ample. The course of study covers four years of seven months each, and is graded. Total fees for the first year are $70, second $60, third $50, and $75 for the fourth year. The Dean is Dr. Waldo Briggs, 1405 Olive St., St. Louis. Total number of students registered, 1900-1, was 243; graduates, 52. The twenty-third session began September 17, 1901, and ends April 9, 1902.

American Medical College.—Eclectic. It was organized in 1873, and has a faculty of 14 professors, and 13 clinical instructors, a total of 27. Metropolitan Hospital, containing 40 beds, and a college dispensary supply clinical material. The requirements for admission are those of the National Confederation of Eclectic Medical Colleges, of which this college is a member. The course of study covers four years of twenty-six weeks each. The total fees for the first two years are $80 each, third year $75, and $100 for the fourth year. Total registration for 1900-1 was 75; graduates, 16. The Dean is Dr. E. Younkin, St. Louis. The present session opened September 16, 1901, and closes March 25, 1902.

Homeopathic Medical College of Missouri.—This was organized in 1882 and has a faculty of 26 professors and 5 demonstrators and assistants. Clinical facilities are offered by the City Hospital, Children's Free Hospital and a college dispensary. The curriculum covers four years of seven months each. Fees: First year, $80; second, $75: third, $60, and $85 for the fourth year. The Dean is Dr. W. B. Morgan, St. Louis. Total registration for 1900-1 was 66; graduates, 11. The present session opened September 10. 1901, and closes April 17, 1902.

Marion-Sims Beaumont Medical College.—By the recent union of Marion-Sims, which was organized in 1890, and Beaumont Hospital Medical College, organized in 1886, the present school has been founded. The faculty is composed of 36 professors, 20 lecturers and assistants, and 4 demonstrators, a total of 60. Clinical facilities are offered by Alexian Brothers' Hospital, with 250 beds; St. Mary's Hospital, containing 200 beds; Rebekah Hospital, having a capacity for 50 patients; St. Mary's Infirmary, containing 150 beds; the City Hospital and Insane Asylum, each with a capacity of 600 patients. Grand Avenue Dispensary also furnishes good material for practical instruction. The requirements for admission are those outlined by the Association of American Medical Colleges, of which this college is a member. The buildings afford ample laboratory and lecture-room space and they are well equipped. The course of study embraces laboratory and clinical instruction, with recitations and lectures. The curriculum covers four years of seven months each. The total fees for the first year are $85; for the second and third, $80 each, and $100 for the fourth. The Secretary is Dr. H. W. Loeb, St. Louis. Total number of students registered for 1900-1 was 366; graduates, 87. The next session opens October 1, 1901, and closes May 1, 1902.

Washington University Medical Department.—This school was organized in 1891 from the St. Louis Medical College, which was organized in 1841, and in 1899 the Missouri Medical College, organized in 1840, was added. The faculty comprises 33 professors, 19 clinical professors and lecturers, and 4 instructors, a total of 56 Clinical material is furnished by the St. Louis Mullanphy Hospital, St. John's Hospital, the Polyclinic and Bethesda Hospitals and O'Fallon Dispensary; the out-patient departments also furnish good opportunities for clinical study. In addition to these, the City Hospital, French Hospital, Insane Asylum and Poorhouse is used in common with the other schools. The requirements for admission are claimed to be those of the Association of American Medical Colleges. The college buildings, of which there are two, furnish good laboratory and lecture-room facilities. The course is four years of seven months each, and the system of study embraces laboratory, didactic and clinical teaching. The total fees for the first year, $121: second, $116, and for the third and fourth years, $100 each. The Dean is Dr. J. B. Shapleigh, St. Louis. Total registration of students for 1900-1 was 227; graduates, 54. The next session opens September 26, 1901, and closes May 8, 1902.

Barnes Medical College.—This school was organized in 1892, and has a faculty of 24 professors, 9 lecturers, and 11 assistants and instructors, a total of 44. The clinical advantages are those offered by Centenary Hospital, with 150 beds; City Hospital; the college dispensary and the outdoor obstetrical department. This college is a member of the Association of American Medical Colleges and the requirements for admission are those prescribed by [illegible] The laboratories are well equipped and other [illegible] course of study includes graded work for four [illegible] each. The total fees for the first three years are $75 each, and $85 for the fourth year. The Secretary is Dr. Pinckney French, Century Bldg., St. Louis. Total registration for 1900-1 was 520; graduates, 111. The ninth session opens Sept. 23, 1901, and closes April 11, 1902.

Kansas City.

Kansas City Medical College.—This was established in 1869, and has a faculty made up of 19 professors, and 12 lecturers, demonstrators, etc., in all 31. The clinical facilities are those of St. Joseph's Hospital, which also contains an out-patient department; the City Hospital, St. Margaret's Hospital, Scarritt Hospital, St. Anthony's Home for Children and the college dispensary. This college is a member of the Association of American Medical Colleges and its requirements for admission are governed by the rules of that Association. The building is large and well equipped, the course is graded and the classes in practical work are divided into sections of ten each, in order that personal instruction may be obtained. The curriculum embraces four years of seven months each. The total fees for the first two years are $75 each, for the third $80, and $85 for the fourth. The Dean is Dr. Andrew S. Fulton, Deardoff Bldg., Kansas City. Total registration of students for 1900-1 was 114; graduates, 44. The thirty-third session opened Sept. 17, 1901, and closes March 21, 1902.

University Medical College.—This was organized in 1881 as the University of Kansas City Medical Department and in 1888 was reorganized under its present name. Its faculty comprises 21 professors, 11 adjunct professors and lecturers, and 14 assistants, a total of 46. Clinical material is furnished by the University Hospital, the City Hospital, German Hospital, Home for the Aged, containing 147 beds; the Sisters' Hospital, Scarritt and St. Margaret's Hospitals, the Children's Home, St. Joseph's Orphan Asylum, and the college dispensary and obstetric department. Instruction is given by means of lectures, recitations, demonstrations, and laboratory work and clinics. The requirements for admission are those of the Association of American Medical Colleges, of which this school is a member. The college building, which has been recently enlarged, furnishes ample accommodations for laboratories and lecture rooms. The course of study covers four years of six months each, and the work is graded. The total fees for each of the first two years are $80, for the third $60, and $85 for the fourth year. The Dean is Dr. Samuel C. James, Junction Bldg., Kansas City. The total number of students registered in 1900-1 was 246: graduates, 69. The twenty-first session began Sept. 9, 1901, and ends March 26, 1902.

Kansas City Homeopathic Medical College.—This school was organized in 1888 and has a faculty of 32 men. The City Hospital, Homeopathic Hospital, the Sanitarium, Scarritt, University, Women's and Children's, German, Bethany and Children's Hospitals are open to its students for clinical study. The college dispensary and clinics also supply clinical material. Applicants for admission must show by diploma, certificate or examination that they have a sufficient knowledge of English, arithmetic, geography, United States history, and Latin equal to one year's work. The course covers four years of seven months each. Total registration for 1900-1 was 50; graduates, 12. The fourteenth session began Sept. 9, 1901, and closes April 1, 1902. [Recently consolidated with the Kansas City University College of Homeopathic Medicine and Surgery, under the name, Hahnemann College of Kansas City.]

Woman's Medical College.—This school was organized in 1895, and has a faculty composed of 27 professors, 7 lecturers and assistants, and 3 special lecturers, a total of 37. Material for clinical study and demonstration is furnished by St. Joseph's, Scarritt, German, Sisters', Agnew, St. Margaret's and City Hospitals, and the college dispensary. The requirements for admission are those determined by the Association of American Medical Colleges. The course of study embraces graded work for four years of seven months each. The total fees for the first year are $68; second, $60; third, $55, and $80 for the fourth year. The Dean is Dr. Nannie P. Lewis, 1219 Wyandotte St., Kansas City. Total number of matriculants for 1900-1 was 23; graduates, 9. The seventh session opened September 18, 1901, and closes March 27, 1902.

Medico-Chirurgical College.—This school was organized in 1897 as the Kansas City College of Medicine and Surgery of Kansas City, Kan., and was reorganized the following year under its present name. Its faculty embraces a total of 46. Clinical facilities are furnished by the hospitals of Kansas City used in common by the medical colleges, and a college dispensary. The course covers four years of six months each. The fees are: For the first year, $70; second, $65; third, $55, and $75 for the fourth year. The Dean is Dr. George O. Coffin, Kansas City. Total registration for 1900-1 was 117; graduates, 25. The present session opened September 17, 1901, and closes March 20, 1902.

Eclectic Medical University.—Eclectic. This is a new school, organized in 1898, with 20 names in its faculty. The catalogue claims that the curriculum covers four years of six months each. Fees, about $70 each year, with a graduation fee of $15. The Dean is Dr. C. Palmer, Kansas City. Total students for 1900-1 was 48; graduates, 14. The next session begins Sept. 16, 1901, and ends March 14, 1902.

Columbia.

Department of Medicine of the University of the State of Missouri.—This department was organized at Columbia in 1872. The faculty embraces 9 professors, 8 lecturers and assistants, and 8 instructors, a total of 25. The Parker Memorial Hospital and the Boone County Infirmary supply the clinical material. Applicants for admission are required to show by certificate that they possess educational acquirements which are about equivalent to a good high school education. The laboratories and lecture rooms are large and well equipped; in the scientific work they are the same as used by the other departments of the University, and they are under the charge of the heads of the different chairs. The training in the technical studies and laboratory work is excellent. The course covers four years of nine months each, and the work is graded. A combined course of six years is offered, conferring the degrees of both Arts and Medicine. There is no charge for tuition, the only expense being a library fee of $5 each year and the actual cost of the materials used in the laboratories. The Dean is Dr. A. W. McAlester, Columbia. Total registration of students for 1900-1 was 85; graduates, 11. The present session opened Sept. 10, 1901, and closes June 4, 1902.

St. Joseph.

Ensworth Medical College.—This was organized in 1888, and has a faculty of 18 professors and 5 lecturers and assistants, 23 in all. St. Joseph's Medical Hospital, with 250 beds; City Hospital, containing 40 beds; the State Hospital No. 2, which is open to the students once a week, and a college dispensary furnish clinical material. Applicants for admission must show by certificate or examination, that they possess a sufficient knowledge of English, arithmetic, algebra, physics and Latin equal to one year's instruction. The building furnishes ample laboratory and lecture-room facilities. The curriculum covers a graded course of four years of six months each. The fees are about $55 each for the first three years, and $75 for the fourth year. The Dean is Dr. Jacob Geiger, St. Joseph. The present session opened Sept. 16, 1901, and closes March 17, 1902.

Central Medical College.—This school was organized in 1894, and has a faculty made up of 16 professors and 14 lecturers, in all 30. The Methodist and St. Joseph's Hospitals, State Hospital No. 2, and the City and County Hospitals are available for clinical study; a college dispensary also supplies clinical material. The requirements for admission are the possession of a certificate for work completed, or an examination. The curriculum embraces four years of six months each. Fees: First year, $55; second, $50; third, $40, and $65 for the fourth year. The Secretary is Dr. T. E. Potter, St. Joseph. Total enrolment for 1900-1 was 57; graduates, 2. The seventh session began September 2, and will end March 1, 1902.

NEBRASKA.

Nebraska, population 1,066,300, has three medical colleges: Omaha Medical College, Lincoln Medical College, and John A. Creighton Medical College.

Omaha.

Omaha Medical College.—This is the Medical Department of the University of Nebraska ar [illegible] 881. It is situated in Omaha, a city with a [illegible] and its faculty is composed of 24 professors [illegible] s and lecturers, and 3 assistants, a total of 36. The Douglas County Hospital, accommodating 300 patients; Bishop Clarkson Memorial Hospital, Immanuel Hospital, the Omaha Methodist Hospital and the college dispensary furnish good material for clinical study and demonstration. This college is a member of the Association of American Medical Colleges and its requirements for admission are governed by that organization. The college building is well adapted for its purpose and the laboratories and lecture rooms are commodious and completely equipped. The course of work embraces graded studies covering four years of seven months each. The method of instruction is made up of didactic and clinical lectures, demonstrations, quizzes and laboratory work. The total fees for the first two years is $80 each, and $85 for each of the last two years. Board and lodging can be obtained for from $3 to $5 a week. The Secretary is Dr. Ewing Brown, Omaha. Total number of students registered in 1900-1 was 149; graduates, 23. The twenty-first session begins September 24, 1901, and will end April, 1902.

John A. Creighton Medical College.—This school was organized in 1892, and is also situated in Omaha. It is the Medical Department of Creighton University, and has a faculty of 27 professors, 8 associates and lecturers, and 7 assistants, a total of 42. The clinical facilities are those of St. Joseph's Hospital, containing 300 beds and having a clinical amphitheater connected with it; St. Bernard's Hospital, with 160 beds; Douglas County Hospital, Presbyterian Hospital, and the college dispensary; the material is abundant and varied. The requirements for admission are those of the Association of American Medical Colleges, of which organization this school is a member. [illegible] s completed in 1898, contains excellent [illegible] nd lecture-room work, and the equipment [illegible] of instruction, including clinical, didactic and laboratory work, special emphasis is laid upon practical work. The course of study embraces four years of eight months each. The total fees for the first two years is $80 each, and $85 for the last two years. The Dean is Dr. D. Bryant, McCague Bldg., Omaha. Total number of students registered in 1900-1 was 123; graduates, 27. The ninth session opens September 15, 1901, and closes April 15, 1902.

Lincoln.

Lincoln Medical College.—Eclectic. This school was organized in 1889, and is situated in Lincoln, a city of 40,169 people. It has a faculty of 23 professors and 2 lecturers. The college dispensary furnishes clinical material. The requirements for admission are those of the National Confederation of Eclectic Medical Colleges, of which this college is a member. The course of study covers four years of twenty-eight weeks each. The total fees for the first year is $83; second, $78; third, $70, and $65 for the fourth year. The Dean is Dr. W. S. Latta, Lincoln. Total number of students for 1900-1 was 74; graduates, 12. The present session began September 15, 1901, and ends April, 1902.

NEW HAMPSHIRE.

New Hampshire, population 411,588, contains *one* medical college.

College.—This school is the Medical De- College, and is located in Hanover, popula- was organized in 1797. Its faculty is made up of 14 professors and 3 demonstrators, 17 in all. The Mary Hitchcock Memorial Hospital, a college hospital of 36 beds, supplies the clinical material. Applicants for admission must possess an education at least equivalent to graduation from a registered high school. The laboratories of the academic department afford good facilities for work in physics, biology and chemistry. The course covers four years of twenty-six weeks each. Total fees for the first three years are $110, and $135 for the fourth year. The Dean is Dr. William T. Smith. The total number of students registered for 1900-1 was 89; graduates, 27. The work for the entering class begins with that of the academic department, commencing in September and closing in June; for the advanced classes it begins in July and ends in February.

NEW YORK.

New York State, population 7,268,894, has ten medical colleges. Seven of these, College of Physicians and Surgeons, Long Island College Hospital, New York Homeopathic Medical College, New York Medical College, Eclectic Medical College, Cornell University Medical College and the University and Bellevue Hospital Medical College are located in New York City, population 3,437,202. This city, with its hospitals and dispensaries, offers abundant clinical material. Board and lodging can be obtained for from $5 to $7 a week.

Albany Medical College is located in Albany, a city of 94,151 people, where board and room can be had for from $4 to $5 a week.

The University of Buffalo Medical Department is situated in Buffalo, population 352,387; here board and lodging can be obtained for from $3.50 to $5 per week.

The College of Medicine, Syracuse University, is in Syracuse, a city with 108,374 inhabitants. Board and lodging can be procured for from $3.50 a week upwards.

The laws of the state of New York require of the prospective student of medicine a preliminary education equivalent to that obtainable in a four years' course in any of the public high schools recognized by the regents as maintaining a satisfactory standard. Upon proof of at least this amount of education, a medical-student certificate will be issued by the state authorities. The colleges, therefore, have a common standard for the requirements of admission.

New York City.

College of Physicians and Surgeons.—This school was organized in 1807 and its present relation, that of medical department of Columbia University, was assumed in 1860. The faculty embraces 21 professors, 18 clinical and adjunct professors and 43 demonstrators, instructors, etc., a total of 82. The new Vanderbilt Clinic, where 48,967 patients were treated during the year 1900 and which is equipped with all modern appliances for the study and treatment of disease, and Sloane Maternity Hospital, containing 116 beds, offer exclusive clinical advantages to students of this school. Besides these, Roosevelt Hospital, containing 238 beds; New York Hospital, with 150 beds; Bellevue, 850 beds; Presbyterian, 330 beds; St. Luke's, General Memorial, and New York Foundling Hospitals, together with the Eye and Ear Institute, containing 40 beds, St. Mary's Free Hospital for Children, and the Hospital for the Ruptured and Crippled, all offer free clinical teaching to matriculants of this school. The laboratories, lecture rooms and amphitheaters are ample in equipment and accommodation; special provisions are made to equip each student thoroughly in each of the laboratories and thus make the work individual. The work is graded, covering four years of eight months each. The total fees for the first year are $205; for the second and third, $200 each, and $225 for the fourth year. The Dean is Dr. James W. McLane, New York City. Total registration for 1900-1 was 801; graduates, 149. The next session begins Oct. 7, 1901, and ends June 11, 1902.

Long Island College Hospital.—This was organized in 1856, and has a faculty of 11 professors, 13 adjunct and clinical professors and 45 lecturers, instructors, etc., a total of 69. Long Island College Hospital, containing 300 beds and being connected with a four-story maternity hospital; Polhemus Memorial Clinic, and Hoagland Laboratory, com most modern apparatus, are all a part o nical facilities furnished by these, n d at Kings County, St. John's, Brookl Methodist Episcopal and the Brookly re the students are offered opportun y of these also contain out-patient advanced students to attend personally to cases. Bedside instruction is also given in the wards. The course covers four years of thirty weeks each. Fees: First year, $190; second, $195; third, $160, and $145 for the fourth year. The Dean is Dr. Jarvis S. Wight, New York City. Total registration, 1900-1, was 187; graduates, 47. The forty-third session opens Oct. 1, 1901, and closes May 15, 1902.

New York Homeopathic Medical College and Hospital.—Homeopathic. This school was organized in 1858 and has a faculty of 27 professors and 21 lecturers, instructors, etc., 48 in all. Flower Hospital, adjoining the college and having a completely equipped out-patient department, Metropolitan Hospital, New York Ophthalmic Hospital and the Laura Franklin Free Hospital for Children furnish the clinical facilities. The course covers four years of seven months each. Total fees for the first year, $110; second, $130 third, $125, and $155 for the fourth year. The Dean is Dr. Wm. T. Helmuth, 504 Fifth Ave., New York. Total number of students registered for 1900-1 was 107; graduates, 127. The next session begins Oct. 2, 1901, and ends May 8, 1902.

New York Medical College and Hospital for Women.—Homeopathic. This school was organized in 1863, and has a faculty of 19 professors, 5 adjuncts and 19 lecturers and assistants, a total of 43. The college hospital and dispensary, the Memorial Hospital for Women, Metropolitan, Flower and the Laura Franklin Free Hospital for Children afford clinical material. The course covers four years of thirty weeks each. Fees: First year, $125; second, $110; third, $100, and $130 for the fourth year. The Dean is Dr. M. Belle Brown, 30 W. 51st St., New York. Total registration for 1900-1 was 33; graduates, 9. The next session opens Oct. 1, 1901, and closes May 14, 1902.

Eclectic Medical College.—This was organized in 1865 and has a faculty of 12 professors and 23 lecturers, demonstrators, etc., 35 in all. A college dispensary, Manhattan and Red Cross Hospitals and Muncie Sanatorium supply clinical facilities. The work covers four years of seven months each. Total fees: First year, $125; second, $120; third, $105, and $130 for the fourth year. The Dean is Dr. George W. Boskowitz, New York. Total registration for 1900-1 was 84; graduates, 12. The next session opens Sept. 24, 1901, and closes May, 1902. This school is a member of the National Confederation of Eclectic Medical Colleges.

Cornell University Medical College.—This department of Cornell University was established in 1898. The faculty is composed of 12 professors, 19 clinical professors, 31 instructors, and 36 clinical instructors and assistants, a total of 98. The City Hospital, having 1000 beds; Bellevue Hospital, New York Hospital, Presbyterian, Willard Parker and Reception, with 200 beds; New York Skin and Cancer; St. Francis, having a capacity of 230 beds; St. Vincent's, with 200 beds; the Manhattan Eye and Ear Hospital, and the Eye and Ear Infirmary, in addition to a large college dispensary, furnish the clinical resources; the material is abundant and varied. The first two years of the course are taken at Ithaca and the work is devoted to the fundamental scientific subjects. The last two years are spent mostly in practical and clinical work and the hospital advantages are utilized. The Loomis Laboratory, a five-story modern building, is well equipped and supplies ample practical laboratory facilities required in the advanced work. "The essential feature of the entire system is the division of the classes of the several years into small sections." Fees: First year, $190; second and third, $180 each, and $200 for the fourth year. The Dean is Dr. William M. Polk, New York. Total registration for 1900-1 was 356; graduates, 26. The next session opens Sept. 24, 1901, and closes June 19, 1902.

University and Bellevue Hospital Medical College.—This is a department of the New York University, and was founded in 1898 by the union of the New York University Medical College, organized in 1841, and the Bellevue Hospital Medical College, organized in 1861. The faculty is composed of 30 professors, 33 clinical professors and lecturers, and 50 instructors, demonstrators, etc., in all 113. Bellevue and City Hospitals, Hospitals of the Workhouse and Almshouse, Manhattan State Hospital for the Insane, Willard, Parker and Reception Hospitals, Riverside Hospital for Contagious Diseases, Randall's Island, Presbyterian, St. Luke's, St. Vincent's, General Memorial, Gouverneur, Columbus, Harlem, New York Foundling, and the Society for the Lying-in Hospitals, the New York Eye and Ear Infirmary, and a large college dispensary are open to students of this school for a study of clinical cases. The Carnegie building, a new five-story structure adjoining the college, is devoted to laboratory instruction and investigation, and, with the other two large college buildings, affords good laboratory and lecture room facilities. The course of instruction covers four years of seven months each. Actual clinical teaching, in conjunction with and founded upon laboratory work, recitation and didactic teaching, is emphasized to the greatest possible degree. Fees: First year, $185; second and third, $180 each, and $195 for the fourth year. The Dean is Dr. Edward G. Janeway, New York City. Total registration for 1900-1 was 285; graduates, 43. The next session opens Oct. 2, 1901, and closes June 5, 1902.

Albany.

Albany Medical College.—This school was organized in 1838, and in 1873 it assumed its present relations, as medical department of Union University. The faculty is composed of 13 professors, 10 adjunct and clinical professors, and 32 lecturers, instructors and assistants, a total of 55. Albany, St. Peter's, Child's and County Hospitals, South End Dispensary, Eye and Ear Infirmary and the Albany Hospital for Incurables, also the free dispensaries connected with each, are open to students for clinical study. The curriculum embraces graded work for four years of six months each. Teaching is carried on in the laboratories, clinics and lecture rooms. Examinations are held twice a year in all subjects. Fees: First year, $135; second, $120; third, $110, and $130 for the fourth year. The Dean is Dr. Albert Vander Veer, Albany.

Total registration for 1900-1 was 142; graduates, 28. The next session opens Sept. 24, 1901, and closes March 6, 1902.

Buffalo.

University of Buffalo Medical Department.—This was organized in 1846 and has a faculty made up of 26 professors, 27 adjunct and clinical professors, and 15 lecturers, etc., a total of 68. Buffalo General Hospital, Hospital of the Sisters of Charity, Erie County and German Hospitals and the German Deaconess' Home supply ample clinical material for study. A college dispensary, recently organized, is also of value in practical work. The buildings and hospitals are well equipped for clinical and laboratory work. *Bedside instruction is insisted upon and the senior students* are permitted to assist in operations and give anesthetics. This school is a member of the Association of American Medical Colleges. The course covers four years of seven months each. The total fees are: First year, $455; second, $55, and $15 each for the third and fourth years. The Dean is Dr. Matthew D. Mann, 37 Allen St., Buffalo. Total registration for 1900-1 was 212; graduates, 46. The fifty-sixth session opens Sept. 30, 1901, and closes May 2, 1902.

Syracuse.

College of Medicine, Syracuse University.—This school was organized in 1872, as the medical department of Syracuse University. The faculty is composed of 16 professors and 25 lecturers, instructors, etc., in all 41. Clinical facilities are furnished by St. Joseph's Hospital, with a capacity for 200 patients; Hospital of the House of the Good Shepherd, Syracuse Hospital for Women and Children, Onondaga County Orphan Asylum, and the Syracuse Free Dispensary. The laboratories and amphitheaters are large and well equipped. This school is a member of the Association of American Medical Colleges. The curriculum embraces a four years' graded course, eight months making a school year. The total fees for each of the four years are $125. The Dean is Dr. Henry D. Didama, 424 S. Salina St., Syracuse. Total number of students registered for 1900-1 was 116; graduates, 19. The next session opens Oct. 1, 1901, and closes June 11, 1902.

NORTH CAROLINA.

North Carolina, population 1,893,810, has three medical schools. They are, Leonard School of Medicine, North Carolina Medical College, and the University of North Carolina Medical Department. The latter school does not confer degrees.

Leonard School of Medicine.—This school was established in 1882 by the American Baptist Home Mission Society, for the purpose of training colored students of medicine. It is located in Raleigh, a city of 13,643, and has a faculty of 8 teachers. A free hospital and dispensary supplies clinical material. A preliminary entrance examination is given to applicants not possessing a certificate or diploma of educational requirements. The course covers four years of six months each. The total fees for each year are $75. The dormitory plan is adopted generally, and board and room costs $2 a week. The Dean is Dr. James McKee, Raleigh. Total enrolment for 1900-1 was 98; graduates, 18. Next session opens Sept. 28, 1901, and closes March 15, 1902.

North Carolina Medical College.—This school was organized in 1893 and has a faculty of 6 teachers. It is located at Davidson, a village of 904 people, and a small hospital supplies the clinical facilities. The course covers but three years of eight months each. The requirements for admission claimed are those established by the Association of American Medical Colleges. Fees: First year, $90; second year, $85, and $100 for the third year. The President is Dr. J. P. Monroe, of Davidson. The present session began Sept. 5, 1901, and closes May 12, 1902.

University of North Carolina Medical Department.—This is a school not conferring degrees, but embracing the first two years of medical instruction covered in that time by the better class of medical colleges. It was organized in 1891. It is a member of the Association of American Medical Colleges, and its certificate of work completed is accepted by all colleges that are members of that association.

OHIO.

Ohio, population 4,157,545, has twelve medical colleges. Six of these, the Medical College of Ohio, Eclectic Medical Institute, Miami Medical College, Cincinnati College of Medicine and Surgery, Pulte Medical College and the Laura Memorial Woman's Medical College, are located in Cincinnati, a city of 325,902 inhabitants. The clinical advantages of Cincinnati are good; besides many smaller hospitals, the Cincinnati Hospital, where 4940 patients were treated in 1900, is open to the students for study. Board can be procured in Cincinati for from $3 to $5 per week.

Cleveland, population 381,768, contains three medical schools: Western Reserve University Medical College, Cleveland College of Physicians and Surgeons and the Cleveland Homeopathic Medical College. The City Hospital, with 275 beds, is used in common by them for clinical study. Board and lodging can be had for from $2.50 to $5 a week.

Columbus, population 125,560, contains two: Starling Medical College and Ohio Medical University. Board and lodging cost from $2.50 to $5 per week.

Toledo, with 131,822 people, has one medical school: Toledo College of Medicine. It has good clinical advantages. Board and room can be had for from $3 to $5 per week.

The laws of Ohio require that in order to practice medicine in this state, any student not possessing a diploma or certificate showing that he is possessed of the educational advantages required, must pass a satisfactory examination, under the direction of the State Board of Medical Registration and Examination, in the following subjects: English, including rhetoric and spelling; geography, arithmetic, algebra, physics, botany, United States history, and Latin equal to a year's work. This is the standard adopted by all the medical colleges in the state.

Cincinnati.

Medical College of Ohio.—This is the Medical Department of the University of Cincinnati, organized in 1819, and has a faculty made up of 19 professors, 22 lecturers, demonstrators, etc., a total of 41. Good Samaritan Hospital, with 400 beds, Cincinnati Hospital and a well-equipped college dispensary furnish clinical facilities. The buildings supply ample laboratory and lecture-room space, and their equipment is good. The course of study is graded and covers four years of seven months each. This school is a member of the Association of American Medical Colleges. The total fees are for the first year, $105; for the second and third, $100 each, and $125 for the fourth year. Total registration of students for 1900 was 200, graduates 60. The Dean is Dr. P. S. Conner, Cincinnati. The eighty-third session begins Oct. 2, 1901, and ends May, 1902.

Eclectic Medical Institute.—Eclectic. This school was organized in 1845, and has a faculty of 29 members. The Seton Hospital, Cincinnati Hospital, and a college dispensary furnish clinical material. It is a member of the National Confederation of Eclectic Medical Colleges. The course covers four years of twenty-eight weeks each. The fees are $75 for each year, with a graduation fee of $25. The Dean is Dr. F. J. Locke, Newport, Ky. Total enrolment 1900-1, was 141, graduates 26. The next session begins Sept. 23, 1901, and closes April 15, 1902.

Miami Medical College.—This school was organized in 1852 and has a faculty of 18 professors and 16 lecturers and demonstrators, a total of 34. The clinical facilities are furnished by the Cincinnati Hospital and a college dispensary. This college is a member of the Association of American Medical Colleges. The curriculum embraces a four-year graded course of seven months each. The total fees are, for the first year, $115; for the second and third, $110, and $130 for the fourth year. The Secretary is Dr. Oliver P. Holt, 134 W. Ninth St., Cincinnati. Total registration for 1900-1 was 112; graduates, 25. The next session opens Oct. 1, 1901, and closes May, 1902.

Cincinnati College of Medicine and Surgery.—This school was organized in 1852, and has a faculty of 21 professors and 16 lecturers, demonstrators, etc., 37 in all. St. Mary's, Cincinnati, the Jewish, and Christ's Hospitals supply material for clinical study. This school is a member of the Association of American Medical Colleges. The work covers four years of seven months each, and is graded. The total fees for the first three years are $75 each, and $100 for the fourth year. The Dean is Dr. F. V. Fitzpatrick, 32 Garfield Place, Cincinnati. Total enrolment for 1900-1 was 82, graduates 16. The next session opens Sept. 26, 1901, and closes May, 1902.

Pulte Medical College.—Homeopathic. This was organized in 1872 and [illegible] f 22 professors and 9 assistants, 31 in all. [illegible] thesda Hospital, and a college dispensary [illegible] The curriculum covers four years of seven months each. Fees: First year, $80; for the second and third, $75 each, and $100 for the fourth. The Dean is Dr. J. D. Buck, Cincinnati. Total enrolment for 1900-1 was 39, graduates 5. The next session opens Oct. 2, 1901, and closes May 6, 1902.

Laura Memorial Woman's Medical College.—This school was formed in 1895 and has a faculty of 19 professors and 7 assistants, in all 26. Presbyterian and Cincinnati Hospitals and a college dispensary supply material for clinical study; the out-patient department of Presbyterian Hospital is open to students of this school exclusively. This college is a member of the Association of American Medical Colleges. The course embraces four years' study of seven months each. The total fees are $50 for each year. The Dean is Dr. John M. Winthrow, Cincinnati. Total registration of students for 1900-1 was 24, graduates 5. The next session opens Sept. 26, 1901, and closes May 1, 1902.

Cleveland.

Western Reserve University Medical College.—This department of Western Reserve University was organized in 1843. Its teaching faculty includes 19 professors, 17 lecturers and demonstrators, and 20 assistants, a total of 56. The clinical facilities are offered students of the school by Lakeside Hospital, having 250 beds; St. Vincent's Hospital, with 75 beds; City Hospital, containing 150 beds; Home of Maternity, and a college dispensary. The buildings afford ample laboratory and lecture-room space, and the equipment is good; a new clinical laboratory has recently been added. This college is a member of the Association of American Medical Colleges. The curriculum embraces four years' work, of eight months each. The total fees are $125 for each year. The Dean is Dr. Benjamin L. Millikin, 278 Prospect St., Cleveland. Total enrolment for 1900-1 was 133, graduates 24. The next session begins Oct. 2, 1901, and ends June 12, 1902.

Cleveland College of Physicians and Surgeons.—This school was organized in 1863, but did not assume its present name and become the Medical Department of Ohio Wesleyan University until 1896. The faculty is composed of 25 professors and 22 associates, lecturers, etc., 47 in all. Cleveland General Hospital, City Hospital, St. Alexis and St. John's Hospitals, and a college dispensary are available for clinical study. Beginning Sept. 18, 1901, the work was made continuous, the calendar year being divided into three terms of four months each; the work of two terms constitutes the maximum amount of credit that can be obtained in a collegiate year, four years being necessary for graduation. This school is a member of the Association of American Medical Colleges. The total fees for the first two years are $130 each, and $110 for the last two years. The Dean is Dr. C. B. Parker, 425 Euclid Ave., Cleveland. Total enrolment for 1900-1 was 78, graduates 15. The present term began Sept. 18, 1901.

CLEVELAND HOMEOPATHIC MEDICAL COLLEGE.—Homeopathic. This school was founded in 1890 by a consolidation of Cleveland University of Medicine and Cleveland Medical College. The faculty includes 29 professors and 16 adjuncts, lecturers, etc., 45 in all. The clinical facilities are obtained from the Cleveland Homeopathic Hospital, and a college dispensary. The course embraces four years of thirty weeks each. Fees: First year, $110; second and third years, $105 each, and $125 for the fourth year. The Dean is Dr. Gaius J. Jones, Cleveland. Total number of students registered 1900-1 was 150, graduates 46. The present session opened Sept. 18, 1901, and closes April 9, 1902.

Columbus.

STARLING MEDICAL COLLEGE.—This school was organized in 1847 and has a faculty composed of 13 professors and 16 lecturers, associates, etc., a total of 29. St. Francis Hospital, which is under the control of this faculty, Hawke's Hospital, of Mt. Carmel, and a college dispensary are available for clinical study. This college is a member of the Association of American Medical Colleges. The laboratory and lecture-room space is ample. The work covers four years of seven months each. Fees: First year, $73; second, $71; third, $60, and $80 for the fourth year. The Dean is Dr. Starling Loving, Columbus. Total enrolment for 1900-1 was 173, graduates 32. The present session opened Sept. 11, 1901, and closes April 10, 1902.

OHIO MEDICAL UNIVERSITY.—This school was organized in 1890 and has a faculty of 26 professors and 5 assistants, 31 in all. The Protestant Hospital, Ohio Penitentiary Hospital, and a college dispensary provide material for clinical work. The amphitheaters and laboratories are well equipped. This school is a member of the Association of American Medical Colleges. The course embraces work over four years of seven months each. Fees: First year, $86; second, $79; third, $51, and $61 for the fourth year. The Dean is Dr. George M. Waters, Columbus. Total number of students enrolled for 1900-1 was 228, graduates 45. The present session began Sept. 11, 1901, and ends April 15, 1902.

Toledo.

TOLEDO MEDICAL COLLEGE.—This school was organized in 1882 and has a faculty made up of 18 professors and 16 lecturers and assistants, in all 34. Toledo Hospital, St. Vincent's and Robinwood Hospitals, Lucas County Infirmary Hospital, Toledo State Hospital for the Insane and a free dispensary supply good clinical facilities. This college is a member of the Association of American Medical Colleges. The curriculum embraces four years of seven months each. The fees are $75 for each year with a matriculation fee of $5, payable once. The Secretary is Dr. Park L. Myers, 1921 Franklin Ave., Toledo. Total enrolment for 1900-1 was 55, graduates 8. The next session opens Sept. 26, 1901, and closes April 24, 1902.

OREGON.

Oregon, population 413,536, has two medical colleges: Medical Department Willamette University, and University of Oregon, Medical Department.

MEDICAL DEPARTMENT WILLAMETTE UNIVERSITY.—This school is situated in Salem, a town of 4,258 people, and was organized in 1864. The faculty consists of 17 teachers. Clinical facilities for study are supplied by Salem Hospital, and a college dispensary. This school is a member of the Association of American Medical Colleges. The course embraces four years' work of six months. Fees: First year, $110; second, $100; third, $75; and $50 for the fourth year. Board and lodging costs from $3 to $5 a week. The Dean is Dr. W. H. Byrd, Salem. Total enrolment for 1900-1 was 27, graduates 5. The next session begins Oct. 2, 1901, and ends April 2, 1902.

UNIVERSITY OF OREGON MEDICAL DEPARTMENT.—This department of the State University was organized in 1887 and has a faculty of 15 professors and 11 special lecturers, a total of 26. It is situated in Portland, population 90,426. Good Samaritan and St. Vincent's Hospitals, containing 200 and 350 beds respectively, furnish good material for clinical study. The requirements for admission are those of the Association of American Medical Colleges. The college building is modern and well equipped, presenting ample teaching facilities. The course is four years of six months each. Fees: First year, $142.50; for the second and third, $137.50 each, and for the fourth the only fee is $7.50 for examination fee. Board and room can be obtained for from $4 to $6 a week. The Dean is Dr. Simeon E. Josephi, Portland. Total number of students for 1900-1 was 64, graduates 11. The next session opens Oct. 1, 1901, and closes April, 1901.

PENNSYLVANIA.

Pennsylvania, population 6,302,115, has six medical colleges. Of these Philadelphia, having a population of 1,293,697, contains five, as follows: University of Pennsylvania Department of Medicine, Jefferson Medical College, Hahnemann Medical College, Woman's Medical College of Pennsylvania, and the Medico-Chirurgical College of Philadelphia. The clinical facilities of Philadelphia present abundant and varied material for study. Besides the individual hospitals connected with each of the schools the charity hospitals are open to all the students in common. Board and lodging cost from $4 a week upwards.

The other school, Western Pennsylvania Medical College, is situated in Pittsburg, a city of 321,616 people. The cost of board and lodging is from $4 to $6 a week.

A preliminary examination is required of all applicants for a license to practice medicine or surgery in the state. This examination is held at stated intervals by the State Examiners, and includes: (a) English composition, grammar and rhetoric; (b) mathematics, covering algebra and plane geometry; (c) elementary physics, and (d) United States history, and (e) Latin equivalent to a year's study. Upon passing a successful examination a medical-student certificate is issued to the applicant. This certificate will admit the possessor to matriculation in any medical college in the state.

Philadelphia.

UNIVERSITY OF PENNSYLVANIA MEDICAL DEPARTMENT.—This is the oldest medical college in this country, having been organized in 1765 as the medical department of the College of Philadelphia; the first degree was granted in 1768. When the University of Pennsylvania was organized, in 1782, it became the medical department of the University, its present relation. The faculty is made up of 19 professors, 7 clinical professors, and 77 assistants, lecturers, etc., a total of 103. Abundant and varied clinical material is furnished by the University Hospital, where during 1899 there were 9215 cases treated; Maternity Pavilion, with 50 beds; Philadelphia Hospital, containing 1000 beds; Pennsylvania, Children's and German Hospitals, and the Southeastern Hospital and Dispensary. Special attention is paid to bedside instruction and to thoroughly practical work. Applicants for admission must furnish evidence of the education required to enter the academic department of the University. The buildings known as Medical Hall, Laboratory Hall and the Laboratory of Hygiene supply excellent laboratory and lecture room facilities and they are well equipped. The course embraces study for four years of eight months each. The total fees for each year are $200 each, with a matriculation fee of $5 for the first year. The Dean is Dr. John Marshall, Philadelphia. Total enrolment for 1900-1 was 565; graduates, 160. The next session opens October 2, 1901, and closes June, 1902.

JEFFERSON MEDICAL COLLEGE.—This school was organized in 1826, and has a faculty of 15 professors, 11 clinical and adjunct professors, and 58 lecturers [illegible] total of 84. Jefferson Hospital, together [illegible] partment, are used exclusively by students [illegible] study. Bedside instruction is given daily to small sections of the senior class. In addition the following hospitals are open for study of clinical cases: Pennsylvania [illegible] seph's, German, Municipal and Will's Eye [illegible] ge is a member of the Association of Ameri [illegible] and applicants for admission must conform to the regulations of that association. The course of study covers graded work for four years of eight months each. The laboratories are large and well equipped, a new five-story laboratory building having recently been added; the lecture rooms and amphitheaters are also ample. The tuition is $150 a year, with a matriculation fee of $5, paid but once. The Dean is Dr. James W. Holland, Philadelphia. The total number of students for 1900-1 was 736; graduates, 106. The next session opens October 1, 1901, and closes May 29, 1902.

HAHNEMANN MEDICAL COLLEGE AND HOSPITAL.—Homeopathic. This was organized in 1848 and has a faculty of 15 professors and 42 lecturers, instructors, etc., in all 57. Hahnemann College Hospital and Pennsylvania Hospital furnish material for clinical work. The requirements for admission are those established by the Intercollegiate Committee of the American Institute of Homeopathy. The work covers four years of thirty weeks each. Fees: First year, $105; second and third, $125 each, and $155 for the fourth year. Total number of students for 1900-1 was 264; graduates, 52. The Dean is Dr. Pemberton Dudley, Philadelphia. The next session begins September 30, 1901, and will end May 15, 1902.

WOMAN'S MEDICAL COLLEGE OF PENNSYLVANIA.—This school was organized in 1850, and has a faculty of 11 professors, 19 clinical and assistant professors, and 23 lecturers, etc., in all 53. Clinical facilities are offered exclusively to this college by the Woman's Hospital, West Philadelphia Hospital for Women. Other clinical advantages offered are those of the Pennsylvania, German, Children's and Philadelphia hospitals, Will's Hospital for Diseases of the Eye and the Philadelphia Lying-in Charity. This school is a member of the Association of American Medical Colleges, and the requirements for admission are those established by the organization. The lecture room and laboratory equipment is good. The curriculum covers four years of eight months each. Fees: First year, $141.50; second, $138.50; third, $135.50, and $100.50 for the fourth year. The Secretary is Dr. C. N. Pierce, Philadelphia. Total enrolment for 1900-1 was 175; graduates, 37. The fifty-second session begins September 26, and will end May 22, 1902.

MEDICO-CHIRURGICAL COLLEGE OF PHILADELPHIA.—This school was organized in 1881 and has a faculty made up of 19 professors, 10 clinical and associate professors, and 43 lecturers, demonstrators, etc., 72 in all. Opportunities for clinical study are offered exclusively to students of this school by the Medico-Chirurgical Hospital, with 130 beds; Chilren's Hospital, containing 40 beds, and a maternity hospital having 40 beds. In common with other schools the following are used: Philadelphia, Pennsylvania, German, Samaritan, St. Joseph's, St. Agnes', St. Mary's, Methodist and the Philadelphia Lying-in Hospitals. Applicants for matriculation must follow the rules of the Association of American Medical Colleges, to which this school belongs. With laboratories, lecture rooms and amphitheater this college is amply provided and the equipment is good. The work embraces four years of eight months each. Fees: First two years, $140 each; third year, $130, and $100 for the fourth year. The Dean is Dr. Seneca Egbert, 4814 Springfield Ave., Philadelphia. Total enrolment for 1900-1 was 408; graduates, 67. The next session opens October 1, and will close May 24, 1902.

Pittsburg.

WESTERN PENNSYLVANIA MEDICAL [illegible] cal Department of the Western [illegible] Medi- was organized in 1886. The facu [illegible] and [illegible] professors, and 30 associates, assistants, etc., 68 in all. Clinical material for study is furnished by a college dispensary, and the Emma Kaufman Clinic, Reineman Maternity Hospital, Mercy, South Side and

St. John's hospitals. This school is a member of the Association of American Medical Colleges and matriculants must be possessed of acquirement prescribed by that organization. Well-equipped laboratories provide ample facilities for individual work; the lecture-room space is sufficient. The course of study embraces graded work for four years of eight months each. Special attention is given to practical bedside work. The total fees are $130 for each year. The Dean is Dr. J. C. Lange, Pittsburg. Total enrolment for 1900-1 was 338; graduates, 73. The next session begins October 1, and will close Mav 29, 1902.

SOUTH CAROLINA.

South Carolina, population 1,340,316, has one medical college,

The Medical College of South Carolina.—This is situated in Charleston, a city of 55,807 people, and was founded as the Medical College of South Carolina in 1823; ten years later it was reorganized under its present title. The faculty is made up of 10 professors and 14 adjuncts, assistants, etc., 24 in all. The clinical facilities are those offered by the City Hospital, where surgical, obstetrical and medical instruction is given. Applicants for matriculation must show by certificate or examination that they possess the education required of second-grade teachers in the public schools. The course covers four years of six months each. The total fees for each of the first two years are $100, and $75 each for the last two. Board and room can be obtained for from $12 to $16 a month. The Dean is Dr. Francis L. Parker, Charleston. Total enrolment for 1900-1 was 95: graduates, 35. The next session opens October 1, 1901, and closes April, 1902.

TENNESSEE.

Tennessee, population 2,020,616, has ten medical colleges. Of these the Medical Department of the University of Nashville, Vanderbilt University Medical Department, University of Tennessee Medical Department, and Meharry Medical College are situated in Nashville, a city with a population of 80,865. The City Hospital, containing 100 beds, is used by all the schools in common for clinical study. Board and lodging cost from $3 to $4 a week. Knoxville, population 32,637, contains two colleges, Tennessee Medical College and Knoxville Medical College. The cost of room and board in that city is from $2.50 to $4 a week. Chattanooga Medical College and Chattanooga National Medical College are situated in Chattanooga, a city of 30,154 people. Board and lodging cost there from $1.50 a week upwards. There is one college, Memphis Hospital Medical College, located in the growing city of Memphis, population 102,320. Good board can be obtained for from $3 to $4 a week. The other school, the Sewanee Medical College, is located at Sewanee, a mountain town of 1200 people.

Nashville.

Medical Department University of Nashville.—This school was established in 1850, and has a faculty of 14 professors, and 13 lecturers, assistants, etc., in all 27. This school is a member of the Southern Medical College Association and the requirements for admission prescribed by that organization are enforced. The course of study covers four years of twenty-six weeks each. The total fees for each of the four years are $65. The Dean is Dr. William G. Ewing, Nashville. Total enrolment for 1900-1 was 182; graduates, 66. The next session begins October 1, 1901, and ends April 2 1902.

Vanderbilt University Medical Department.—This school was founded in 1874, and in 1895, when the present medical building was completed, the course was extended, the standard raised, and the present faculty. consisting of 10 professors and 20 associates, lecturers, etc., appointed. The [illegible] admission are those of the Southern Medical [illegible] of which this school is a member. The course [illegible] six months each. The total fees for the first three years are $105 each, and $130 for the fourth year. The Dean is Dr. William L. Dudley, Nashville. Total enrolment for 1900-1 was 211; graduates, 92. The next session begins October 1, 1901, and ends April 3, 1902.

University of Tennessee Medical Department.—This was organized in 1876 as the Nashville Medical College; its present relations, as Medical Department of the University of Tennessee, were assumed in 1879. The faculty is composed of 14 professors, and 13 lecturers, assistants, etc., 27 in all. The requirements for admission are those of the Southern Medical College Association, of which this school is a member. The course of study includes work for four years of six months each. The total fees for each of the first two years are $100; third year, $90, and $115 for the fourth year. The Dean is Dr. Paul F. Eve, 614 Broad St., Nashville. Total enrolment for 1900-1 was 182; graduates, 75. The next session begins October 1, 1901, and ends April, 1902.

Meharry Medical College of Walden University.—Colored. This school was organized in 1876 as the Medical Department of Central Tennessee College, now Walden University, "for the purpose of furnishing to the colored people of the South an opportunity obtaining a medical education." The faculty is made up of 9 professors, and 11 instructors, demonstrators, etc., 20 in all. This school is a member of the Association of American Medical Colleges, and the requirements for admission are those prescribed by that Association. The work embraces a four-year graded course, six months to the year. The total fees for the first three years are $40 each, and $50 for the fourth year. The Dean is Dr. G. W. Hubbard, Nashville. Total registration for 1900-1 was 217; graduates, 39. The twenty-fifth session begins September 21.

Knoxville.

Tennessee Medical College.—This school was organized in 1889, and has a faculty of 13 professors and 6 assistants, 19 in all. A college hospital and a free dispensary supply material for a study of clinical cases. This school is a member of the Southern Medical College Association, and the requirements for admission are those prescribed by that Association. The curriculum includes graded work for four years of six months each. Fees: First year, $75; second, $70; third, $67.50, and $94 for the fourth year. The Secretary is Dr. Henry J. Kelso, Knoxville. Total number of students for 1900-1 was 97; graduates, 35. The thirteenth session begins October 1, 1901, and closes April 1, 1902.

Knoxville Medical College.—Colored. This school was established in 1900 following the discontinuance of the Medical Department of Knoxville College, organized in 1895. The teaching force comprises 11 professors. The City Hospital and a college dispensary supply clinical material. Applicants for admission not possessing a certificate of the necessary educational requirements "must pass a satisfactory examination." The catalogue says that the course covers four years of six months each. Fees: First year, $42; second, $37; third, $30, and $40 for the fourth year. The Dean is Dr. E. L. Randall, Knoxville. Total number of students for 1900-1 was 34; graduates, 4. The next session opens December 4, 1901, and closes May 30, 1902.

Chattanooga.

Chattanooga Medical College.—This is the Medical Department of Grant University and was organized in 1889. The faculty is made up of 12 professors, and 22 demonstrators, instructors, etc., in all 34. Erlanger Hospital and a free college dispensary supply material for a clinical study of cases. The catalogue says that before an applicant for graduation can matriculate he must present a certificate showing that he is possessed of scholastic attainments equal to those required for a first-grade teacher in the public schools. The course of work covers four years of six months each and is graded. The total fees for the first, third and fourth years are $75 each, and $85 for the second year. The Dean is Dr. E. A. Cobleigh, Chattanooga. Total enrolment for 1900-1 was 224; graduates, 54. The thirteenth session begins October 7, 1901, and ends April 15, 1902.

Chattanooga National Medical College.—Colored. This was chartered in 1899 and shows a teaching force of 9. "The college has a large lecture room, two recitation rooms, one dissecting and a large pharmaceutical room." The catalogue claims that the course covers four years of seven months each. Total fees are $50 each year, with an additional graduation fee of $20. Total enrolment for 1900-1 was 20; graduates, 2.

It was the presentation of a diploma from this school, for a license to practice, in connection with other facts, that convinced the legislature of Tennessee of the necessity of state control. Hereafter all who expect to practice in that state must stand a state examination, except matriculates of Tennessee colleges who graduate before July, 1902.

Memphis.

Memphis Hospital Medical College.—This school was organized in 1878, and has a faculty composed of 10 professors and 15 assistants, 25 in all. Good clinical facilities are furnished by St. Joseph's Hospital, the City Hospital, with 200 beds, and a college dispensary. It is a member of the Southern Medical College Association. The course includes graded work for four years of six months each; "this, however, applies only to students who matriculated for the first time on or after January 1, 1899." With the addition of a large new building, ample laboratory and lecture-room space is afforded: facilities for practical laboratory work, in connection with the study of clinical cases, have also been added. The total fees for the first two years are $75 each, and $105 for the last two. The Dean is Dr. W. B. Rogers, Memphis. Total registration for 1900-1 was 750; graduates, 189. The twenty-second session begins November 1, 1901, and ends April, 1902.

Hannibal Medical College.—Colored. Some twenty years ago there was chartered under the laws of Tennessee an organization under this name, but there never has been an attempt to carry on regular lectures. Diplomas have been issued at various times, but always to negroes. It is thought that the recently enacted state law, compelling an examination, will abolish this practice.

Sewanee.

Sewanee Medical College.—This is a three-year school and is the Medical Department of the University of the South. It was organized in 1891 and has a faculty of 7 professors, and 14 associates, lecturers, etc., 21 in all. The requirements for admission are those of the Southern Medical College Association, of which this school is a member. The course covers three years of six months each, but the catalogue says that after 1902 four years will be required. The fees are $65 for each of the first two years, and $90 for the last year. The Dean is Dr. John S. Cain, Sewanee. Total enrolment for 1900-1 was 207; graduates, 102. The tenth session commenced July 3, 1901, and will close January 1, 1902.

TEXAS.

Texas, population 3,048,710, has four medical colleges. The University of Texas Department of Medicine is located at Galveston, a city of 37,789 inhabitants. Good board and room can be procured for from $15 to $20 a month. The Medical Department of Fort Worth University is at Fort Worth, population 26,888. The cost of board and room in that city is from $12 to $15 a month. The other two colleges, University of Dallas Medical Department and Dallas Medical College, are situated in Dallas, population 42,638.

Galveston.

University of Texas Medical Department.—This department of the State University was organized in 1891, and has a faculty of 9 professors, and 15 lecturers, assistants, etc., a total of 24. The John Sealy Hospital, also having an outdoor department, and St. Mary's Infirmary supply good material for clinical study. The requirements for admission are proof, either by certificate or examination, that the candidate is sufficiently proficient in English, including grammar, composition and rhetoric; mathematics, through plane geometry and algebra including quadratics, and general history. The curriculum embraces graded work for four years of eight months each. Fees, to residents of the state: First year, $50; second, $20; third, $15, and $5 for the fourth year. Non-residents of the state are required to pay an additional fee of $50 each year. The Dean is Dr. Henry P. Cooke, Galveston. Total registration for 1900-1 was 119; graduates, 6. The next session begins October 1, 1901, and ends June 1, 1902.

Fort Worth.

Medical Department Fort Worth University.—This school was organized in 1894, and has a faculty of 17 professors, and 14 lecturers, assistants, etc., in all 31. Clinical facilities are supplied by St. Joseph's Hospital, with 200 beds; the Benevolent Home, containing 75 beds; the Delia Collins' Rescue Home, having 50 beds, and a college dispensary. The requirements for admission are those of the Southern Medical College Association, of which this school is a member. Instruction is carried on by laboratory, didactic and clinical study. The course covers four years of six months each. The total fees for each of the first three years are $75, and $100 for the fourth year.. The Dean is Dr. Bacon Saunders, Fort Worth. Total enrolment for 1900-1 was 157; graduates, 27. The next session opens October 1, 1901, and closes April 3, 1902.

Dallas.

University of Dallas Medical Department.—This school has but completed its first year. The faculty shows a teaching force of 23. Parkland Hospital, with 90 beds; St. Paul's Sanitarium and a college dispensary are utilized for clinical study. Applicants for admission not possessing a certificate of sufficient work done, "must pass a satisfactory examination before a committee of the faculty." The course covers four years of six months each. The fees are $75 for each of the four years, with a matriculation fee of $5, and a graduation fee of $25, each paid but once. The Dean is Dr. Charles M. Rosser, Dallas. Total registration for 1900-1 was 81: graduates, 15. The second session opens October 1, 1901, and closes April 1, 1902.

Dallas Medical College.—This school has also completed but one year of its existence, recently becoming the Medical Department of Trinity University. The catalogue shows a faculty of 18, and requires four years of six months each for the graduation of all who matriculated after January 1, 1899. The City Hospital, Polyclinic Infirmary and a college dispensary supply clinical material. The requirements for admission claimed are those of the Association of American Medical Colleges, but this school is not a member. Fees: $75 each year for general fee; matriculation fee, $5, and $25 for graduation. The Dean is Dr. Jesse B. Titterington, Dallas. Total enrolment for 1900-1 was 51; graduates, 8. The second session begins October 28, 1901. and ends April 30, 1902.

VERMONT.

Vermont, population 343,641, has one medical school,

Medical Department University of Vermont.—This school is located at Burlington, a town of 18,640 people; it was organized in 1822, but suspended from 1836 until 1854, when it was reorganized. The faculty consists of 20 professors, and 14 adjuncts, instructors, etc., in all 39. The Mary Fletcher Hospital and a free dispensary furnish material for clinical instruction. Applicants for admission must show by certificate or examination sufficient knowledge of the following: English, including grammar, orthography and composition; geography, United States history, arithmetic and elementary physics. The laboratory and lecture room space and equipment are good. The course of study embraces graded work for four years of six months each. The total fees for each of the first three years are $115, and $114 for the fourth year. Board and room costs from $3.50 to $5 a week. The Secretary is Dr. B. J. Andrews, Burlington. Total registration of students for 1900-1 was 155; graduates, 15. The forty-ninth session begins January 2, 1902, and ends June 25, 1902.

VIRGINIA.

Virginia, population 1,854,184, has three medical colleges. The University of Virginia Department of Medicine is situated in Charlotteville, having a population of 6449. Board and room can be obtained at that place for $18 a month and upwards. The other two colleges, Medical College of Virginia and University College of Medicine, are located at Richmond, a city of 85,050 inhabitants. The clinical facilities are good and board and room can be obtained there for from $12 to $20 a month.

University of Virginia Medical Department.—This school was organized in 1825, and has a faculty of 7 professors, and 10 lecturers, instructors, etc., in all 17. A free dispensary furnishes clinical facilities for the present, but the new four-story hospital, now almost completed will add greatly in that direction. The requirements for admission claimed are those of the Association of American Medical Colleges, but this school is not a member of that Association. The course of study embraces four years of nine months each. Fees: First year, $110; second, $100; third, $80, and $60 for the fourth year. Total enrolment for 1900-1 was 173; graduates, 53. The seventy-seventh session opened September 15, and will close June 18, 1902.

Medical College of Virginia.—This school was organized in 1838 as the Medical Department of Hampden Sidney College, and in 1854 the present name was assumed. The faculty is made up of 15 professors, and 20 lecturers, instructors, etc., a total of 35. Clinical material is furnished by the Old Dominion Hospital, Maternity Hospital, and the City Dispensary; an outside obstetric department also furnishes opportunities for clinical work. This school is a member of the Southern Medical College Association, and the requirements for admission are those determined by that Association. The buildings are large and contain well equipped laboratories and amphitheaters. The course embraces four years of seven months each. The fees are $65 for each year, with an additional graduation fee of $30. The Dean is Dr. Christopher Tompkins, Richmond. Total registration for 1900-1 was 203; graduates, 47. The next session begins October 1, 1901, and will end May 3, 1902.

University College of Medicine.—This school was organized in 1893 and has a faculty of 17 professors, 32 lecturers, assistants, etc., a total of 49. Good clinical facilities are furnished by Virginia Hospital, with a maternity department and annex which was built especially for the purpose of affording clinical instruction; Richmond Eye, Ear and Throat Infirmary, containing 34 beds; the City Hospital, and a college dispensary. Applicants for matriculation must show by certificate or examination to be possessed of a certain proficiency in English, mathematics and Latin. The laboratory and lecture-room space and equipment are ample. The curriculum covers four years of seven months each. The total fees are $85 for each year. The Dean is Dr. J. Allison Hodges, Richmond. Total enrolment for 1900-1 was 224; graduates, 72. The next session begins October 1, 1901, and ends May 15, 1902.

WISCONSIN.

Wisconsin, population 2,069,042, has two medical colleges, the Milwaukee Medical College and Wisconsin College of Physicians and Surgeons. They are both situated in Milwaukee, a city of 285,315 people. Clinical facilities are furnished them in common by the County Hospital, with 175 beds, and the Milwaukee Hospital for the Insane. Board and lodging can be had for from $3 to $5 a week.

Milwaukee Medical College.—This school was organized in 1893, and has a faculty of 22 professors, 7 associates, and 28 lecturers, instructors, etc., a total of 57. Good clinical material is furnished by Trinity, St. Mary's, and the County hospitals, Milwaukee Hospital for the insane, and a college dispensary. This school is a member of the Association of American Medical Colleges, and the requirements for admission are those specified by that body. Ample laboratory and amphitheater facilities are afforded. The course covers four years of seven months each. The total fees are $60 each for the first three years, and $70 for the fourth year. The Dean is Dr. William H. Earles, Milwaukee. Total number of students for 1900-1 was 178; graduates, 36. The eighth session began September 18, and will close April 15, 1902.

Wisconsin College of Physicians and Surgeons.—This college was organized in 1893, and has a faculty composed of 24 professors, and 22 associates, assistants, etc., a total of 46. St. Joseph's Hospital, containing 150 beds; Wisconsin Maternity Hospital, a college dispensary and the material used in common with the other school supply ample facilities for clinical study. The requirements for admission are those of the Association of American Medical Colleges, of which this school is a member. The laboratories and lecture rooms are well equipped. The curriculum includes work for four years, seven and one-half months constituting a year. Fees: Matriculation, paid once, $5; general ticket for each semester, $40; for the use of microscope, a fee of $2 is charged for each course. The Secretary is Dr. J. A. Bach, Milwaukee. Total enrolment for 1900-1 was 123; graduates, 18. The next session begins September 24, 1901, and ends May 13, 1902.

THE ASSOCIATION OF AMERICAN MEDICAL COLLEGES.

Regarding the requirements for admission to be maintained by colleges belonging to this Association. They are as follows:

Section 1.—Each college holding membership in this Association shall require of each student, *before admission* to its course of study, an examination, the minimum of which shall be as follows:

1. In *English*, a composition on some subject of general interest. This composition must be written by the student at the time of the examination, and should contain at least 200 words. It should be criticised in relation to thought, construction, punctuation, spelling, and handwriting.

2. In *Arithmetic*, such questions as will show a thorough knowledge of common and decimal fractions, compound numbers, and ratio and proportion.

3. In *Algebra*, such questions as will bring out the student's knowledge of the fundamental operations, factoring, and simple quadratic equations.

4. In *Physics*, such questions as will discover the student's understanding of the elements of mechanics, hydrostatics, hydraulics, optics, and acoustics.

5. In *Latin*, an examination upon such elementary work as the student may offer, showing a familiarity usually attained by one year of study; for example, the reading of the first 15 chapters of Cæsar's Commentaries, and the translation into Latin of easy English sentences involving the same vocabulary.

Sec. 2.—In place of this examination, or any part of it, colleges, members of this Association, are at liberty to recognize the official *certificates of reputable* literary and scientific colleges, academies, high schools, and normal schools, and also the medical student's certificate issued by any state examining board covering the work of the foregoing entrance examination.

Sec. 3.—Colleges, members of this Association, may allow students *who fail in one or more branches* in this entrance examination the privilege of entering the first-year course, but such students shall not be allowed to begin the second course until the entrance requirements are satisfied.

Sec. 4.—Colleges, members of this Association, are free to honor official *credentials issued by medical colleges of equal requirements*, except in the branches of study embraced in the last year of their own curriculum.

Sec. 5.—Candidates for the degree of Doctor of Medicine in the year 1899 and thereafter shall have attended at least *four courses*

---

[1] No information to be obtained except that such college is in existence.

[2] Some are also teachers in day schools.

[3] Some are in both departments of this university.

[4] Does not grant degrees.

[5] Colored.

[6] Just organized.

[7] Apparently grants any degree.

[8] Could not be ascertained.

[9] Recently consolidated under the name, Hahnemann College of Kansas City.

of medical instruction, each course of at least six months' duration, no two courses of which shall have been in the same calendar year.

SEC. 6.—Colleges, members of this Association, are free to give to students who have met the entrance requirements of the Association additional *credit for time* on the four years' course as follows: (*a*) To students having the A.B., B.S., or equivalent *degree* from reputable literary colleges, one year of time; (*b*) To graduates and students of colleges, of *homeopathic or eclectic* medicine, as many years as they attended those colleges, provided they have met the previous requirements of the Association and that they pass an examination in materia medica and therapeutics; (*c*) To graduates of reputable colleges of *dentistry, pharmacy,* and *veterinary* medicine, one year of time.

SEC. 7.—A college not giving the whole four courses of the medical curriculum, and not graduating students, but otherwise eligible, may be admited to membership.

THE SOUTHERN MEDICAL COLLEGE ASSOCIATION.

The following extracts from the Constitution show regulations controlling matriculants and fees:

ARTICLE IV.

SECTION 1.—Every student, before being matriculated for the first course of medical lectures in any college belonging to this Association, shall be required to possess the following qualifications:

SEC. 2.—He shall hold a certificate from some known reputable physician, showing his moral character and general fitness to enter upon the study of medicine.

SEC. 3.—He must possess a diploma of graduation from some literary or scientific institution of learning, or a certificate from some legally constituted high school, general superintendent of State education, or superintendent of some county board of public education, attesting that he has been regularly examined and is possessed of at least the educational attainments required of first grade teachers of public schools, or a certificate that he has passed the entrance examination to a State University; and a student may be given one month, from the date of his admission, to submit his certificate of qualification.

* Amend Section 2, Article 4.—After the word "certificate" in the first line, insert "duly sworn to."

* Further amend Section 3, Article 4.—After the word "certificate," in the fourth line from the top insert "duly sworn to;" and after the word "University," in the fourth line from the bottom, insert "or other collegiate institution."

SEC. 4.—A set of tickets showing that the holder has attended one full course of medical lectures in any regular and recognized medical college shall be essential for matriculating for a second course of lectures in any college belonging to this Association; and every student prior to matriculating for a third or fourth course of lectures, shall be required to show, by similar evidence, that he has previously taken two or three courses of lectures.

* Amend Section 4, Article 4, by marking the first paragraph "a," and by adding to this paragraph at the end the following: "The minimum per cent. of actual attendance during any session requisite to credit a student with a full course, shall be 80 per cent. of the collegiate course; and a certificate of such attendance, signed by the Dean or Secretary, shall in all instances be promptly furnished by the college so attended." Amend this Section still further by adding paragraph "b," as follows: "Students shall be examined at the end of the first, and every succeeding year, on the studies of the year, and shall be graded. If a student fail on any of the studies of the year he shall not be credited with a full course, but only with the branches that he has passed successfully. He must be examined on every subject upon which he may have passed an unsatisfactory examination, during the ensuing session, at a time determined by the Faculty.

SEC. 5.—The following classes of students may apply for advanced standing and obtain it, provided every applicant undergoes a satisfactory examination upon every branch below the class desired to be entered:

(*a*) Graduates of Dentistry, of Pharmacy, and of Veterinary Medicine.

(*b*) Graduates and matriculates who have completed one or more courses in Colleges of Homeopathy and of Eclectic Medicine.

(*c*) Graduates of recognized colleges and universities who have completed therein prescribed courses in elementary branches of medicine, including chemistry and biology.

* Amend Section 5, Article 4, by adding paragraph "c" as follows: "Any legally qualified non-graduate practitioner of medicine may be admitted into the second year on passing a satisfactory examination on all of the studies of the first year."

SEC. 6.—The same charges shall be made in each of the courses, except where students are exempt from dissection and from laboratory work by reason of having performed the same before, and are not candidates for graduation; and colleges shall enforce and collect their published rates of charges, except in cases deserving reduction on account of the demands of worthy and deserving charity, and such cases shall not exceed 7 per cent. of the whole number of matriculates of the previous session. This law shall not apply to endowed institutions, whose benefactions are confined to their own State; or to colleges receiving State appropriations, or whose charter privileges compel them to give free scholarships to students of their respective States.

The following is recommended as the minimum rate of charges allowable by colleges belonging to this Association:

Matriculation Fee	$5.00
Professors' Tickets	75.00
Anatomical Ticket	10.00
Laboratory Courses, each..................	10.00
Graduation Fee	25.00

* Amend Section 6, Article 4, by striking out the following: "Except in cases deserving reduction on account of the demands of worthy and deserving charity, and such cases shall not exceed 7 per cent. of the whole number of matriculates of the previous session."

INTERCOLLEGIATE COMMITTEE OF THE AMERICAN INSTITUTE OF HOMEOPATHY.

Under date of Sept. 10, 1901, Dr. George Royal, Secretary of this organization, says: "Every college which secures admission to the Intercollegiate Committee of the American Institute of Homeopathy, must present evidence that they have complied with the requirements of the State Board of Health in their state, or, if there is no such board, then of those of the State Board of the state nearest them. They must show that they teach the principles of similia and agree to be regulated by such rules as the Committee has or may formulate. The following colleges are now in good standing: Denver Homeopathic Medi [illegible] .. Hospital College, San Francisco; Chicag .. [illegible] College; Hering Medical College; Dunham [illegible] .. mann Medical College and Hospital, Chicag [illegible] .. Department University of Iowa; Southwes [illegible] cal College, Louisville; Boston University School of Medicine; Southern Homeopathic Medical College, Baltimore; Homeopathic Medical College University of Michigan; Homeopathic Department University of Minnesota; Hahnemann Medical College of Kansas City University; Homeopathic Medical College of Missouri; New York Medical College and Hospital for Women; Pulte Medical College; Cleveland Homeopathic Medical College; Hahnemann Medical College and Hospital, Philadelphia."

NOTES.

The population given of both city and state is that of the last United States census (1890).

In estimating the time necessary to complete a course of study, the number of weeks in the table should be multiplied by four, except for the three-year schools.

There are but two colleges in the country that do not claim a four-year course, these being the North Carolina Medical College and the Sewanee (Tenn.) Medical College.

Last year an attempt was made by THE JOURNAL to cover the ground in the same manner as has been done this year, but at that time without success as regards certain of the statistics, and that special number was therefore given up. The number of graduates for the school year 1899-1900, however, were obtained, correctly we believe, and were as follows according to states:

Alabama, 56; Arkansas, 8; California, 146; Colorado, 44; Connecticut, 24; District of Columbia, 78; Georgia, 153; Illinois, 681; Indiana, 62; Iowa, 91; Kansas, 49; Kentucky, 166; Louisiana, 118; Maine, 32; Maryland, 262; Massachusetts, 212; Michigan, 228; Minnesota, 69; Missouri, 501; Nebraska, 38; New Hampshire, 30; New York, 436; North Carolina, 20; Ohio, 315; Oregon, 16; Pennsylvania, 502; South Carolina, 43; Tennessee, 600; Texas, 40; Vermont, 40; Virginia, 140; Wisconsin, 39. A total of 5239.

About fifteen colleges were not included in the above, but at the outside these did not graduate over one hundred men and possibly not half that number. We estimate seventy-five and believe this is within fifteen of being correct. This number added would make the total number of graduates for last year (1900) 5314, against 5444 for this year.

There were 23,846 students registered at the regular colleges during the year ending July 1, 1901; 1683 at the homeopathic; 664 at the eclectic, and 224 at the physio-medical and nondescript—a total of 26,417.

There were 4879 graduates from the regular colleges; 387 from the homeopathic; 148 from the eclectic, and 30 from the physio-medical and nondescript—total M.D. degrees conferred during the year, 5444.

There are in all 5,958 teachers in the medical schools of this country.

There are 10 medical colleges located in towns of less than 10,000 inhabitants; 24 in towns between 10,000 and 50,000; 11 in towns between 50,000 and 100,000; 36 in towns between 100,000 and 250,000; 28 in towns between 250,000 and 500,000, and 45 in towns of more than 500,000 inhabitants.

The following states and territories have no medical colleges: Arizona, population 122,931; Delaware, 184,735; Florida, 528,542; Idaho, 161,772; Indian Territory, 392,060; Mississippi, 1,551,270; Montana, 243,329; New Jersey, 1,883,669; New Mexico, 195,310; Nevada, 42, 335; North Dakota, 319,146; Oklahoma, 398,331; Rhode Island, 428,556; South Dakota, 401,570; Utah, 276,749; Washington, 518,103; West Virginia, 958,800, and Wyoming, population 92,531.

In the Table indicating homes of students, those marked foreign include Canadians. This will explain the number in the "foreign" column, in certain colleges located near the border; for instance, Detroit College of Medicine registers fifty students from the Province of Ontario, and Saginaw Valley Medical College has fourteen students registered from the same province.

CANADA.

The Dominion of Canada, with a population of 5,335,055, distributed through seven provinces and the Northwest territories, an area which reaches from the Atlantic to the Pacific, contains only 12 medical colleges. Of these, 5 are situated in Ontario, 4 in the province of Quebec, 2 in Nova Scotia, and one in Manitoba. One of the five colleges in Ontario is merely a teaching body; it does not confer degrees, since it is not in affiliation with any university. The distinction between university and college in Canada is definite, namely, the latter is a teaching body only and has no right to grant a degree. The announcements of the following institutions were not received: 1, Faculty of Medicine, Queen's University, Kingston, Ont., and 2, Manitoba Medical College, affiliated with the University of Manitoba. The course of the latter is four years of eight months each.

Toronto, Ontario.

University of Toronto, Medical Faculty.—All the lectures and demonstrations of the 1st and 2d years are given in the laboratories and lecture rooms of the University; *more than two-thirds* of the instruction in the 3d and 4th years are given in the wards and in the pathological and clinical laboratories. A 5th year is now demanded by the Ontario Medical Council, for which provision will be made. Clinical instruction is given in the Toronto General Hospital, Mercer Eye and Ear Infirmary, Burnside Lying-in Hospital, Hospital for Sick Children, and St. Michael's Hospital. Before commencing students must satisfy, as to qualifications, the College of Physicians and Surgeons of Ontario (Provincial Board). Fees are: Registration (payable once), $5; each of the first four years, $100; fifth year, $50; for the degree of M.B., and M.D., each $20. Number of students registered last session, 339; graduates, 52. The 15th session, since the re-establishment of the Medical Faculty of the University, will commence October 1.

Trinity Medical College.—This college is in affiliation with Trinity University, the University of Toronto, Queen's University, and the University of Manitoba. It is situated in Toronto. Toronto General Hospital, Hospital for Sick Children, St. Michael's Hospital, Burnside Lying-in Hospital, and the Eye and Ear Hospital are open to the students for clinical instruction. The entering candidate must pass the examination required by the Provincial College of Physicians and Surgeons. The fee for each session of eight months is $100, exclusive of fees for examinations and hospitals. Matriculates during last session were 157; graduates, 37. The 31st "consecutive winter session" will begin September 25, and continue for eight months.

Ontario Medical College for Women.—This college is located in *Toronto*, and is *not* empowered to grant degrees in Medicine, but it qualifies students fully to take the examinations in any University. The college requires no certificate of matriculation examination, but will accept that of the university selected by the student. The fee for each year is $100, exclusive of all hospital and university fees. The number of undergraduates last session was 339; graduates, 52. The 18th session will open Septembr 17 and continues for eight months.

London, Ontario.

Medical Department of the Western University.—This college makes use of Victoria Hospital for its clinical work. The fee each year is $90, and $25 for graduation. The requirements for matriculation are those demanded by the College of Physicians and Surgeons of Ontario, and the full course is one of 5 years. The matriculates of last session were 77; graduates, 13. The 20th session opened September 10.

Montreal, Quebec.

University of Bishops College, Faculty of Medicine.—The course leading to the degree of C.M., M.D., extends over four years and consists of 4 sessions of six months each, and three summer sessions of three months each, only one of which is compulsory; the faculty strongly recommends attendance upon the three summer courses. Students who require the Quebec license will be given an extended course to comply with the provincial laws. The Montreal General Hospital, Royal Victoria, Western Hospital, Hotel *Dieu Hospital* and Women's Hospital *afford opportunities* for clinical instruction. Students must, on commencing, satisfy the Provincial Board as to their preliminary qualifications. The fee for the first year is $81; second year, $84; third year, $86; fourth year, $74, and summer course, $25, and degrees, $25. During last session the students numbered 106. The 31st annual session will commence October 1.

McGill University, Faculty of Medicine.—This college has a course of four years of nine months each. The total fees for the course are $500. Clinical instruction is given in the Montreal Gene [illegible] Victoria Hospital, and Montreal Maternity [illegible] except university graduates in arts, must pass [illegible] amination required by the Provincial College of Physicians and Surgeons. Last year's matriculates numbered 490; graduates, 106; post-graduate students, 23. The 70th session will commence September 23.

Ecole de Medecine et du Chirurgie.—This college is the Montreal branch of the Medical Faculty of the Universite-Laval in Quebec. It is a French school and was incorporated in 1845. Its students in all classes now number from 280 to 300 each year.

Quebec, P. Q.

Universite Laval, Faculte du Medecine.—The course consists of four years. The fees for the entire course are $180 and $216, according to preliminary qualifications. The matriculates during last session were 102; graduates, 24.

Halifax, Nova Scotia.

Faculty of Medicine of Dalhousie University.—The course consists of 4 years of 8 months each, and leads to the final M.D. and C.M. examination. Prospective students must pass the preliminary examination of the Provincial Medical Board or a university examination. During last session there were 95 students, of which 14 belonged to the graduating class.

Halifax Medical College.—This college supplies no "preliminary examiners;" students are referred for examination to the Registrar of the Provincial Medical Board,. The course consists of four years of eight months each. The fees for the full course are $300, and $30 for graduation. During last session the students numbered 88; graduates, 12. The 33d session began August 29.

Six Years' Course for the Degree in Arts and in Medicines.—As the number of subjects about which it is necessary for the student to know something has increased during the past years the medical course has gradually been lengthened, the demands upon the student have been greater and the average age at which men enter practice has continually increased. This state of affairs has given rise to a considerable discussion as to whether it is advisable for a young man intending to study medicine to take a preliminary course in arts or sciences. The requirement of such degrees as a condition for entrance at Harvard and Johns Hopkins is sufficient evidence that some of the most progressive and representative members of our profession consider such a course of study not only advisable but indispensable. The poor quality of instruction in our secondary schools is no doubt responsible for the delay of students in entering college, and this has made the average age very high for the student who graduates from both a collegiate and medical course. With improvement in secondary education this state of affairs will be remedied and students will be able to enter upon their professional work at a reasonable age. At present the requirement of the degree in arts and science with a four years' course in medicine is considered too high by many, and various solutions of the problem have been suggested. Certain schools have given credit to graduates in arts and science for studies with a medical bearing taken during their academic courses. Other schools have sought to arrange a schedule of studies which shall give a reasonably complete liberal education in connection with a medical course in a shorter length of time than has been previously customary. Within the past year we have noticed from the announcements of Cornell University, McGill University and the University of Michigan, an arrangement by which students can cover the course and receive both degrees in six years. In Cornell before the establishment of the medical department a number of courses were given in anatomy, physiology, histology, embryology, bacteriology and physics which counted toward the degree in arts. There seems to be no reason why these studies should not be considered general culture courses suited to the student desiring a general education along biologic lines who has not in view the study of medicine. On the other hand, all of these studies are indispensable for the man who is to take up medicine, and if they are taken during the academic course, there is no reason why the medical course should not be shortened by the time required to take them during the academic course. The amount of general culture which the student gets by such an arrangement is about the same that English, French, and German students are now required to have, and while the complete college course with broader culture is desirable if possible, the combination of two courses in six years is a far better arrangement than that the student should not take any college course at all. A number of leading universities have now arranged courses which tend in this direction. For several years it has been possible for the student to obtain the degree in arts at Harvard in three years. The regular course of study at Johns Hopkins is three years, the scientific course at Yale has never been more than three years, and in some colleges and universities the somewhat lower requirements for entrance make the four years' course about the equivalent of a three years' course in other institutions. This shortening of the general culture course is of great importance to the man who must spend at least a year in hospital training as well as four years in the medical school, and we believe that the still more radical change which has been adopted in the universities which we have mentioned might be wisely introduced at other universities. This would not prevent younger men who had the time and inclination from pursuing a more comprehensive course, and it would encourage many men who now go into medicine without the advantage of academic study to try to get this valuable extra two years of training. No doubt the time will come in the future when our medical instruction in the United States will be more nearly uniform in all States, as is the case in nearly all European countries, and this combination six years' course is about what we may expect will be the standard.—*Am. Med.*, Aug. 24.

MEDICAL EDUCATION.

UNIVERSITY WORK IN MEDICINE.

It is no longer necessary for a young man who wants an education first to make the fateful choice between "culture" and professional training. Culture and preparation for a calling in life are not mutually exclusive. Culture that does not prepare for a distinct vocation is a pious fraud. Professional training which does not yield culture is a routine drill in some selected knack. with mind as much as possible left out. Culture that deserves a genuine man's respect is not something apart from the ordinary concerns of life. It is not to be had by withdrawing interest from real work, and devoting attention to a range of thought outside and above and beyond men's practical pursuits. What we really want to express when we praise culture is respect for well-developed, well-balanced, and well-adapted human capacity. There can be no culture which does not consist in doing something well. If there were only one sort of thing which is worth doing well, there would be only one possible culture. As there are innumerable kinds of career. all necessary to progressive human happiness, there are equally numerous possible cultures. The cultured man is he who is not merely mechanically fitted to a social function; but he whose thoughts and feelings work intelligently and harmoniously out into the whole process of life, from the point where his own part has to be done. To fit men for life by fitting them for something different from their life, is an ideal that would be grotesque if it had not so long been sacred. To fit a man for life by giving him insight into the most and best possible in his part in life, and zeal to realize that conception, is the sane and social ideal worthy to guide educational programs.

All this is old and familiar enough. It has ranked. however, as contemptible heresy. It is getting to be practical orthodoxy. It is too much to say that educational authorities have modified their verbal formulas to this extent, but actions still have the most prophetic voice, and the logic of events is arguing the case for rational education almost as fast as the most eager could wish.

With more specific reference to medical education it may be said that there are two contrasted types of demand which medical instruction might be planned to supply. The first may be suggested by supposing the case of a young man who says to himself: "I want to get out of life all there is in it for myself, and I want to do it by means of the medical profession. I want, therefore, to get, in the shortest possible time, all the medical information that I can turn to my uses." The other demand may be put in the form of an imagined expression of the general public interest: "We want a proper quota of men of first-rate natural endowment, to make protection of health their special function. We want them to acquire knowledge, and to develop judgment and skill to the limit of their capacity. We want them to bring all the resources of preventive and remedial medicine to the service of their fellows."

The history of quackery need not be called upon for proof that with very little education, involving practically no culture at all, men are able to achieve notorious successes in satisfying the former type of demand. The ideal of the medical profession is distinctly of the other type. The man who enters into the spirit of the profession wants to be the sort of man that the interests of society require him to be. His education should be of the kind which will do the most to satisfy the general need.

Medical instruction in the universities is adjusting itself very rapidly to these perceptions. The ideal of the scholar is knowledge of everything in its relations. When "pure" scholarship controls educational programs they tend to meander off from concrete affairs until the typical scholar is so interested in everything in general that he is good for nothing in particular. The ideal of the practical man, on the contrary, is ability to bring something specific to pass. When this aim controls education it tends to make trade-schools—places where men learn to turn out piecework of a prescribed pattern. The trade may be preaching or teaching or lawyering or doctoring or carpentering. In effect it is, in either case; rule of thumb work. The union of the technical school and the university provides the best conditions imaginable for proper balance between these tendencies. No knowledge or skill would be absolutely worthless to a medical practitioner or investigator. There are, nevertheless, many kinds of knowledge and skill that would cost a member of the medical profession much more than they are worth. On the other hand, the physician can hardly know too much about his own profession, yet he may concentrate his attention so exclusively upon technicalities as to miss many other things that would make him a more effective man. Every professional man has to fix on a working program between the two extremes. The medical curriculum in our universities is the best proposition that scholars and practical men together can offer at present toward a balance of the different claims.

There are just as sharp differences of opinion as ever among university men about fundamental theories of higher education, but whatever individuals think about the matter the universities are actually moving ahead, as fast as they can see footing for next steps, toward solving the problems of reasonable ratio between the more and the less essential in medical training.

With variations both of kind and degree for latitude and longitude and social stratum, the people with whom American physicians practice demand of the medical profession, and are sure to demand more and more, certain attitudes and habits of mind and certain sorts of information which, whether rightly or wrongly, are regarded as credentials of education. This fact requires at least a certain minimum of attention to those subjects which tradition has pronounced cultural. The physician is a man among men, a citizen among citizens. Not alone in his general relations to the state, but as a frequent incident of his professionl duties, he is called upon for knowledge and judgment about business and law and government. It would be an abortive scheme of education that would omit the rudiments of industrial and civic economy. All the special knowledge which the physician must use consists merely of more particular cases which fall under the general laws of matter. Of course, he must be initiated at least into all the physical sciences. He must know the logic of scientific reasoning, the methods of scientific discovery, and some of the more important results of physical, chemical and biological research. It is not absolutely necessary to read French and German in order to be a progressive physician. It is a prodigious convenience at any rate, and if one wants to be sure of ability to keep among the best informed in his profession he must acquire those languages. The universities are not building a trocha around the medical profession when they propose a program of medical study based upon a foundation which includes all these elements. The standard thus established is justified not by an arbitrary theory of culture, but by calm calculation of the demands which a physician's proper functions must satisfy. In other words, the university influence in medical instruction brings into the curriculum those non-essential factors which a strictly professional training would ignore. These are in some respects more important to the fully equipped physician than the reputed essentials.

The university element assures one more capital factor in medical education. It guarantees that the knowledge which the student gets shall look toward science, and not stop with mere information. The old culture superstition located educational values in certain high caste subjects. We now find culture values not in the things known, but in the way they are known. To know anything in its connections is to be on the way toward all the culture possible. Perception of the relations within things and among things is science. The conduct of medical studies by the universities involves methods which will put the most technical details in scientific organization. Facts will be traced to principles. Phenomena will lead back to laws. Objects and occurrences will get their proper setting both in the genetic series and in the functional organization to which they belong. In the universities, therefore, technical training becomes more precise because it is cultural, and culture becomes more genuine by working out to technical values.

If the physician can not see his facts as they are, and can not draw correct conclusions from pertinent evidence, his failures have more direct and serious consequences than those of any other vocation. When we consider the gravity of the services which society expects of medical men, the highest standard for their education can seem neither too liberal nor too severe.

ON RESEARCH WORK FOR UNDERGRADUATES IN MEDICAL SCHOOLS.

One of the questions which the modern medical student sometimes has to answer during his course rather than at the beginning of it is, "Shall I or shall I not as an undergraduate engage in special research?" The question was formerly but little likely to come up. Teachers, as a rule, knew but little and students less of the real meaning of original investigation. Even those professors who had the capacity to undertake it or to guide it were prevented from doing so by the demands of private practice upon their time or the limitations of the equipment of the colleges. Now, that an increasing number of the occupants of chairs in our best medical schools give up private practice and give their whole time to the subjects which they represent, and are appointed to these chairs not only because they can teach, but because they can produce and are capable of guiding productive study, the conditions are very different. The more earnest and ambitious medical graduates attach themselves to such professors and their laboratories and spend a period of time in attacking problems and solving them, for it is coming to be that demonstration of power in some sort of original work is necessary if a man wishes to enter the lists for the higher successes open to members of the medical profession. The enthusiasm of the capable investigator is enormously stimulating and it is but little wonder that young and eager minds coming into contact with it in the medical school or medical department of a university should themselves be fired with the desire of increasing the world's general stock of knowledge instead of being satisfied merely with gaining information regarding the contributions of others.

It seems to us, however, that, under the present conditions of medical education, for the majority of undergraduate medical students research work is not suitable. We recognize fully the influence of research upon development and the importance of gaining as early as possible in one's career the attitude of mind which alone comes through working for knowledge for its own sake in fields before insufficiently cultivated, but in most instances a student, if he is to occupy himself with it at all, does best to postpone until after he has graduated the undertaking of such work. It is but rarely that the undergraduate student is sufficiently prepared for original work. The average student of medicine has quite enough to do to follow faithfully the regular work of the medical course, and if he can do more than is absolutely required without injury to his health he will usually do best to direct his spare energies toward extending his knowledge beyond the confines of what is demanded in one or more of the fundamental branches. If he succeed in urging an unwilling instructor to put him upon a special problem he too often will neglect his regular studies, or injure his health and fall short of success in both. In such instances the student is injured and his instructor's time is worse than wasted.

There are some exceptions to this general rule; medical curricula are of necessity constructed for average students. In every medical school a few students stand out conspicuously as being especially capable, and the tendency is growing to provide more advanced and special courses for such pupils. Among the men of such a group there may occasionally be one who by virtue of unusual mental capacity, or of special training antedating his entrance upon medical studies, is easily recognized by a teacher as a man capable of undertaking research work during the undergraduate period without detriment to the student or to the school. The higher the standard of entrance to the medical school the greater the probability of finding such men in its classes. If a student be asked by a professor in a good medical school to engage during his course in original research, the student will do well to acquiesce; for, in a good medical school the professors should be men who are capable of sound judgment in such matters; and the responsibility will lie with the teacher rather than with the student. Here is applicable as much as anywhere Goethe's admirable maxim:

Vor den Wissenden sich stellen
Sicher ist's in allen Fällen.

If the student has confidence in his teacher he can not do better than temporarily place himself unreservedly in his hands. He should regard it a great honor and privilege to be chosen to engage in original work and his master's confidence in his ability will make him doubly desirous of proving himself worthy of it. If, on the contrary, a student be ambitious to undertake original investigation and the faculty advise him to devote his whole time and energies to the regular work of the school, he will be wise if he be guided by those best capable of judging as to what is best for him.

While it is undesirable for most undergraduates to undertake any special original research which will require a considerable length of time for its completion, there can be but little doubt of the advantages which accrue to medical students who approach the regular work of the medical course by the methods of research. Perhaps as great an improvement as any recently made in medical education has been the introduction of such methods in the teaching of the regular course. The student may be led to acquire knowledge, in territories already explored, more or less according to the methods used by the original discoverers. In the study of law the "case method" of teaching is analogous. In this far, "research work" may be unreservedly recommended to all undergraduates. The responsibility of the proper conduction of such work depends upon the faculties of our medical schools. The method is past the experimental stage and its success is assured. It will no longer do to urge students to gain their principal knowledge from books. The knowledge which a student really makes his own has to be wrested with a certain amount of difficulty from Nature herself. Books and teachers may be good guides to direct the student in his own work; they are too apt to be harmful when more is expected of them. The utilization of the methods of research—personal observation, reflection and experiment—in the ordinary courses of the medical school will reveal many mistakes in current text-books; properly organized such courses may lead after a few semesters to the accumulation of data which will permit of the correction of various errors and so really constitute a collective original research.

If the class system could be done away with, and it is already falling to pieces in some schools, the objections to undergraduate research work would in large part disappear. At present we disgrace a student who does not graduate in medicine in a stated number of years along with the other members of his "class." It is desirable that the student have liberty to prolong his course without disgrace. When some such arrangement has been perfected it might be advisable for the best students to spend six or even more "Lehrjahre" in completing their training in the fundamental branches by Monographic Work in one or more departments. The course followed by Huxley in his own work before 1860 might well be applied to some extent at least in an undergraduate course of a school of the highest order.

It will be noted that while we are of the opinion that the majority of medical students are unfitted, especially during their undergraduate years, for original research, our reasons for this are different from those brought forward by one of our contributors.[1] His principal argument lies in the assumption that the methods of original investigation in the medical sciences are not only fundamentally different from, but actually injurious to, the "medical mode of thought" which is to be used in observing symptoms, arriving at a diagnosis, and deciding upon a course of treatment. But has he any evidence which would indicate that such an assumption is true? Surely every-day experience points to the opposite view and certainly the statements made in his paper can scarcely be regarded as convincing. It is difficult to understand how a training which teaches a man how to think and work independently can be an injury to his future career or how practice in the weighing of evidence and the arriving at justifiable conclusions should lead to unnecessary deliberation and slowness of judgment. Is it not an error, too, to think that research is limited to the determining of new truths of a general character only, and is it not rather the case that the majority of original investigations deal with particular problems in special fields? Only occasionally does that master-mind appear which is capable of new generalizations, justifiably far-reaching. Again, is it fair to consider that work unworthy of the name of research which, though it fail to say the last word upon the problem upon which it is engaged, gathers all the data at the time available, reflects upon them and draws legitimate inferences from them, even when the result is only an approximation to the whole truth? We think not. Indeed, since the time of Heraclitus, our main consolation after ineffectual attempts to reach the absolute has, perforce, lain in the habit of forming relative judgments. Nor will one regard such relative judgments or tentative conclusions as being devoid of responsibility when it is recalled that one of them may lead thousands of men into action under the most serious circumstances. Finally, does not danger lie in ambush on that road which would lead the "medical mode of thought" too far away from the principles which underlie the accurate observation, logical reflexion and judicious experiment which characterize all scientific methodology? It would not be a far cry, it is to be feared, from such a vagabond mode of thought to that "medical intuition" or *das aerztliche Gefühl* which was formerly accredited with the making of brilliant diagnoses, as it were, "by the Grace of God."

We must confess to seeing but little danger of our medical students or of our medical practitioners becoming too scientific. This country demands not only more scientific physicians in whom the people may safely put their trust, but also more medical scientists capable of properly training them. It is gratifying to find that the medical schools of the better sort are making strenuous efforts to supply both urgent needs.

---

[1] See page 736.

INDEPENDENCE OF STUDY AND THOUGHT IN MEDICAL EDUCATION.

Twenty years ago, when the course for the medical degree was compassed in two five months' sessions, it seemed essential that every moment should be utilized in lectures and clinics and the day's work uniformly consisted of eight or nine hours of lectures and arena clinics, with two or three hours additional of work in the dissecting room or chemical laboratory, the only practical courses given at that time. No time was left the student for study and reflection and it is small wonder that many of the facts presented eluded his comprehension at the time, and that many of them escaped his memory even before his course was completed. Such a system could not fairly be called one of education, but was rather a mere cramming of information.

The most significant fact in the recent remarkable progress in medical education is not the increase in the requirements for admission, nor the longer time now demanded in the course for the degree; it is the change in the methods of teaching, the great development of the laboratory and of the dispensary and ward clinics, and the subordination of the didactic lecture and the arena clinic, which are no longer deemed the all-sufficient means of training for the medical man. It is the object of medical, as of any other education, to develop and train the faculties that the student may acquire the power to observe closely, to record accurately, and to think logically and clearly along medical lines. The acquisition of information is incidental, and, at best, the amount of knowledge which a student can accumulate in his college course is but a small fraction of the sum total of that knowledge; much of that which he does acquire, of the wisest teacher, he may never use. and it is certain that most of the knowledge which he will use in his practice will be acquired during his post-collegiate career. The great purpose of the medical college life, is, therefore, to educate the student how to observe facts, to acquire information, and how to reason logically and closely in reference to them.

How is he to acquire the ability to observe keenly and accurately? Surely, not by reading or by hearing of the observations of others, helpful as this may be, but by the systematic and constant exercise of his own faculties; hence, the great utility of the laboratory and the small clinic in which he is brought in contact with the facts themselves and not with what somebody else has said or written of them. Likewise, he can acquire the power of clear, logical, sustained thought only by the exercise of his reasoning power, not by a mere description of what others have thought, or by the observation of the teacher, clinical or otherwise.

If these statements are correct then time must be allowed the student for study and reflection outside of the hours scheduled for lectures, clinics, recitations and the other stated work of the curriculum. Adequate time for this purpose is provided in very few medical schools of to-day. Almost without exception the curricula are overloaded, too many hours being demanded for scheduled work. This has doubtless resulted from the manner in which the course of study has been constructed. Each professor, duly impressed with the importance of his own subject, has demanded as much time as he could secure for the work of his department. The result has been not only an overloaded curriculum, but in most cases, one very poorly balanced. The amount of time allotted to any particular branch has depended, not on the relative importance of that branch, but on the comparative persistence and persuasiveness of the professor in charge. Evidence of this need only be sought in the wide variation in the courses of study in our numerous colleges. Branches taught in some are not taught in others, and the number of hours allotted to a particular branch in one schedule may be several times that given to it in another.

An effort was made recently to construct a curriculum on a rational basis, which is of interest in this connection. The faculty of this school having determined that radical measures were necessary, set before itself the following propositions: 1. How many hours daily should the average student be expected to devote to work, both in and out of the college? It was agreed that nine hours should be a maximum for students of the first two years, and ten hours for those of the last two years of the medical course. 2. What part of this time should be allotted to scheduled work in the college, and what part to preparation, reading and reflection, outside? 3. What proportion of the scheduled hours should be allotted to lectures and recitations, and what to laboratory, practical, and clinical work? Considering these two queries together, it was agreed that a one-hour lecture or recitation should receive from the average student two hours of preparation, while a two-hour laboratory, practical or clinical exercise would require only one hour of preparation. Three hours, therefore, should constitute a period, whether for lecture, recitation, laboratory, or clinic, with this difference, that in case of the lecture or recitation one hour of the three would be spent in the class room, in the laboratory or clinical period, two hours, would be so spent. It was further decided that for the first two years an equal amount of time should be assigned to lecture and recitation periods on the one hand and to laboratory periods on the other. If, for example, during a certain portion of the year a student has one lecture, and one recitation daily, involving four hours of preparation, and a two-hour laboratory exercise involving one hour of outside work. during another interval he would have only one lecture or recitation and four hours of laboratory work—a total of nine hours of work daily in either case. During the clinical years a larger portion of the time is spent in scheduled work, the amount of time given to clinics and practical courses being larger, but not less than four of the ten working hours daily are allotted for outside study and reflection.

4. The above propositions having been agreed upon, it remained to determine how much time should justly be allotted to each of the required branches of the curriculum. And this, be it noted, was not ascertained by asking each head of department how much time he felt

that he required to teach his branch exhaustively—that being clearly impossible in any case—but by general discussion and conference, as to the relative importance of the several subjects. It is of interest to note in passing how promptly and amicably this question was settled. Heads of departments, previously insistent upon a large amount of time, when faced with the proposition that after all the student had only a given number of hours at his disposal, readily assented to an allotment of hours fairly proportionate to the importance of the several subjects.

This specific case has been cited to illustrate what seems to us a rational method of constructing a course of study, but the most significant feature of it all is the large amount of time allotted to the student for independent reading, reflection—thinking—outside of the scheduled hours. The medical college is not so much a place where the student is to be taught, but a place where he is to be educated, to be given the proper environment for the growth and development of his faculties. The faculty must abandon the idea that he is a reservoir to be placed upon the benches of the lecture room during his every waking hour and stuffed with facts, and accept the idea that he is an observing, thinking mind whose chief need is an opportunity to grow.

THE ELECTIVE SYSTEM IN THE MEDICAL SCHOOL.

Among the modern pedagogical methods which are being discussed in relation to medical education, is the elective system, now so generally adopted by the leading institutions for general learning in this country and abroad. It may be defined as that method under which a student pursuing a course for a degree is allowed some choice in the studies he shall take, the method by which he shall pursue them, and the teachers who shall instruct him. Election finds its chief *raison d'etre* in the fact that individuals differ widely in mental make-up, not only, and not so much perhaps in reference to the sum total of mental capacity, but in the relative strength of the faculties; some men excel in powers of observation, others in memory, others in imagination, and others in reasoning power, and if it be the object of an education to develop a well-balanced, thoroughly-trained mind, it is obvious that, if there are wide differences in the individuals to be trained, the methods of training must differ in different cases.

The acquisition of information is one of the purposes of a college course, and here, too, there is abundant room for election by the individual student, because of the immensity of knowledge. It is obvious that the amount of information which the most diligent student can obtain of any subject during a college course, constitutes but a fraction of the sum total of knowledge therein. A teacher of anatomy, for example, devotes his life to the acquisition and promotion of knowledge of his chosen subject and finds that life all too short for its mastery. While, it is true, there are certain fundamental facts which every student must be taught, it seems clearly impossible for any teacher to select a group of topics, and to present them by any method which shall be the best possible for every individual student. It may, indeed, be safely asserted that no two teachers of anatomy would agree as to what constitutes an ideal course in that subject for a medical student, and this assertion would hold good for teachers in any other branch. Evidence of this is furnished in the widely diverse character of the courses offered in the various medical schools. This being the case, why should not the individual student, aided by the advice of his teachers, be allowed some choice in the matter and permitted to adapt his course of study to his tastes, his abilities, and his needs?

The fundamental idea of the elective system is then, the adaptability of a course of study to the peculiar needs and purposes of the individual student, and it is the opinion of the best educators that ideal results can be procured in no other way. But there are further advantages in the system. Not the least of these is the increased enthusiasm and interest with which the student pursues his work. The difference in the spirit which animates one who is taking courses of his own election, courses which he has taken voluntarily, and not merely because they were prescribed by the faculty, has been noted by almost every teacher who has had to do with them. This difference in spirit reacts in turn upon the teacher and affords him a constant stimulus to faithful and efficient work. It has sometimes happened that an enthusiastic, progressive teacher, having been promoted to an assured place in the faculty, has begun to show a decline in diligence and effectiveness soon after attaining the coveted place. Sure of his position, certain of large classes, his course being required of every student, a strong incentive to good work is removed. Very different is the situation under the elective system; the pupil being allowed to choose the professor's course, or one of several others, offered by ambitious younger men, perhaps assistants in the department, soon begin to discover that the larger experience and knowledge of the older men are more than offset by the eager enthusiasm and energy of the younger assistants, and presently the professor finds that the attendance upon his course is diminishing. Not less important is the opportunity and stimulus afforded to the younger man. Like the privat docent of the German University, he is placed squarely in competition with others and realizes that his future career is in his own hands, to be determined solely by the ability, capacity for work and efficiency which he displays as a teacher and investigator.

Then, too, the very act of election on the part of the student, his careful consideration of his own needs, and the selection of the courses best fitted to them, constitute an educational resource of no mean value.

The chief objections urged against the elective system are, first, the danger that the student will be inclined to specialize, devoting all, or most of his time to one subject, and second, the expense involved in increased space, equipment, and instructors. The advocates of election insist that these objections are invalid. In reference to the danger of specialism, it is said that election does not necessarily imply unlimited freedom of choice as to the general branches to be taken, but that, if the student be allowed some latitude as to the topics under each branch, as to the method of study, whether by lecture, recitation, laboratory or clinic, and as to teachers, all of the benefits of the plan can be secured. A broad and thorough course can be insured by insisting, first, that each student present before graduation a specified minimum of credit in each general branch; second, that his cards of registration be subject to approval of the dean or other officer of the college, and third, that he be required to pass a thorough, practical examination in each department before graduation. It is urged further that the student's own judgment and common sense are prone to be underrated. The number of those is very few who do not realize the necessity of a good knowledge of all of the branches as a preparation for medical practice.

In reference to the need for larger facilities in the matters of space, equipment, and faculty, the advocates of the elective system reply that these must be provided in any event, if the demands of modern medical education are to be met. The subdivision of large classes into small groups for recitation and conference, laboratory and practical exercises, and especially for bedside teaching, is a *sine qua non* for the proper and adequate training of medical men.

A further advantage of the elective plan is the fact that it opens the way for the utilization, under some such scheme as the extra-mural plan of Edinburgh, of many hospitals where no students are admitted at present. This can not well be accomplished except under some plan by which the members of the staff giving instruction are suitably recognized and students are given full credit for work done.

The elective system has been introduced more or less extensively into a number of medical schools. In the Harvard Medical School the Medical Departments of Columbia University, Johns Hopkins University, the University of Pennsylvania, Rush Medical College, and some others, more or less amount of election is allowed. The plan is so generally in use and has been so successful in the larger institutions of general learning that the experience of those medical schools in which it is being tried will be watched with great interest by all who are concerned in any way with medical education.

VALUE OF THE FUNDAMENTAL BRANCHES.

As soon as the student has satisfied the requirements for admission to the study of medicine in some reputable school he may be said to have "burned his bridges" in a much more accurate sense than obtained ten or fifteen years ago. The matriculation examination is becoming yearly more stringent in the larger number of medical colleges, while the demand that the prospective candidate for graduation shall be a person of broad and liberal culture is now more imperative than ever. Time was when the medical student and his friends regarded the freshman as a sort of experimental bread-winner; if the preliminary canter over the medical course did not please him or was not successful any other race could be easily entered. If the boy discovered that he did not care to be a physician, he could take up the grocery business or go back to the farm. Contrariwise, if he failed in, or for any reason abandoned some other occupation, there was always a convenient, and frequently a complaisant, medical "college" to be entered at short notice. A comparison of the Announcements of the previous decade with the present will readily show how much more difficult it now is than it formerly was to carry out the curriculum, and this difficulty is much more likely to increase than diminish. The time is probably at hand when many of the subjects now taught in the freshman and sophomore years will form part of the student's preliminary education.

The additions thus made have an important bearing on the courses commonly known as the fundamental medical branches—biology, anatomy, chemistry, physiology, etc.—because the student must himself decide whether he will attend a college where the latter are mostly disposed of as a part of his preliminary studies and where, consequently, more time is devoted to purely medical investigations, or whether he will undertake them as a portion of the regular collegiate program. It is not our purpose to discuss this matter here except to point out that the pursuit of one or other plan is probably as desirable for one class of students as it is undesirable for another, and that to the average student it matters little when or where he has received such instruction, as long as he does receive it, before engaging in more advanced studies.

Apart from the ambition that most students exhibit to proceed to the final degree, there is a feeling that the subjects of the earlier years are merely means to an end—a sort of ladder on which to climb and when the top is reached to be flung aside as so much useless lumber. It is a common experience to hear even the senior student, not to speak of the recent graduate, glory in the fact that the elements of histology and chemistry, once so familiar to him, are now but a dim memory of that distant past when he was an unsophisticated freshman. While this declaration is not so frequently heard as in former days when the line of demarcation between biology and pathology was more plainly drawn, yet the feeling that there is a great gulf fixed between the theory of the fundamentals and the practice of the bedside has by no means died out.

Is there any reason why, for instance, human anatomy, or embryology or organic chemistry should not be studied, as an introduction to the practice of medicine, with the same persistence and the same singleness of purpose that seems to be so readily accorded to general surgery? If the fundamentals are really essential to his success as a practitioner and to his growth as a scientific man, it is fatal for the student either to neglect them altogether or to regard them, in his after years, as the cast-off clothing of a medical fashion long outworn and fit only for the garret of his mental storehouse.

Probably one of the reasons why in the past certain fundamental studies failed to appeal to students and practitioners of medicine as essential branches was the short time allowed for grasping all the facts and fancies of medical teaching. When the two or three year student (often defective in a preliminary scientific training) was confronted by the mass of material that then, as now, was set forth for him to learn and digest he, perforce, chose the so-called "practical" studies and rejected the others—singing, meantime, the ancient song:

> "Could a man be secure
> That his days would endure
> As, of old, for a thousand long years,
> What things might he know!
> What deeds might he do!
> And all without hurry and care."

We have not recovered, even with the lengthening of the courses of study and the relegation of some branches to the entrance examination, from this feeling that art is long and life is brief.

This neglect of the fundamental branches, in the choice of studies that the student has felt and still may feel it necessary to make as a burden upon his memory, sometimes results from a notion that a large portion of them is, in some sense, more ornamental than useful, just as many educators still cling to that vague idea, current with our grandfathers, that a more or less intimate knowledge of Greek and Latin forms the chief ingredient in the education of a gentleman.

Yet another obstruction in the path of the student was the manner in which the fundamental branches were formerly and—in some colleges are still—taught. Without denying certain inherent virtues in didactic teaching, there can be no doubt but that the mere memorizing of facts in physiology, anatomy and chemistry presented almost entirely in lectures and textbooks during the freshman and sophomore years furnished the most certain means of forgetting them the year after graduation. The embryo physician at the beginning of the twentieth century has, it is safe to say, no such excuse. There are few, even of the smaller colleges, in which the old-fashioned and uninteresting "knife and forceps" anatomy (furtively studied in a foul and nauseating room) is not replaced by demonstrations, recitations, illustrated by models, dried and moist preparations, drawings from the subjects, etc., all carried on in a clean and pleasant laboratory or amphitheater. A corresponding improvement has also taken place in the methods of teaching all the other primary branches, where the laboratory has displaced the old lecture-room, where the student is trained to observe and to record his observations in a manner that will be of the greatest service to him when he is face to face with diseased conditions in after life.

If we accept, in this connection, Spencer's test and inquire what knowledge is of most worth, it is surely not necessary to argue, for example, that without a knowledge of anatomy, general, regional and pathological, surgery would in practice be about as rational and effective (to quote his words) as if "a merchant were to commence business without any knowledge of arithmetic and bookkeeping. We should exclaim at his folly and look for disastrous consequences. Or if, before studying anatomy, a man set up as a surgical operator, we should wonder at his audacity and pity his patients." In like manner, if a knowledge of anatomy be essential to the practice of surgery it is also required in internal medicine, in medical jurisprudence, in obstetrics, in gynecology—in every condition and walk of medical life.

If the intimate relations of anatomical studies to the more advanced subjects of the curriculum be admitted as an axiomatic truth, the importance of physiology—which may be regarded as including biology, embryology and histology—chemistry, pharmacy, etc., to one who desires a lasting and widening knowledge of every other branch of medical learning can not be gainsaid. But this study of fundamental medicine is not to be pursued simply because it is a help in getting "credits" or because it is useful in passing examinations in the final branches. It represents the scientific part of medicine and it certainly begets that most useful and valuable of all habits—the scientific habit. It teaches the student to try and see things as they really are, and, while exercising a rational skepticism, to give due weight to evidence of the proper kind. This is one reason why a conscientious study, in accordance with modern methods, of the subjects of the first semesters is likely to assist the physician in unraveling the tangles of everyday practice, to enable him to keep abreast of the times as he progresses in all useful knowledge, to distinguish false from true, to reject doubtful theories and to help him from being driven hither and thither by every wind of doctrine. Most important of all, a continued study of them furnishes the index by which his fellow practitioners and—at last—the public decide what kind of physician he really is.

To the student who is just entering on his first work we would say: If you wish to be commonplace in every acceptation of that term the way is easy and medical degrees not so very difficult to obtain. If, on the other hand, you desire to live and work among the worthy and be classed among the best no better preparation can be had than setting upon bedrock and keeping in subsequent repair the foundation stones of our temple of art. Against such a defense, the winds and waves of ignorance of both "regular" and "irregular" charlatanism, of exaggerated therapeutics, and of false pathology, will surely beat in vain.

TEACHING BY RECITATION, DIDACTIC LECTURE, THE AMPHITHEATER CLINIC, THE WARD CLASS.

The four methods by which the practical branches of medicine, surgery, obstetrics and the specialties are generally taught are by recitation, by the didactic lecture, by the amphitheater clinic and by the smaller clinic in the dispensary or ward of the hospital, i. e., the ward class. By these methods, with a little practical laboratory work, the student in his junior and senior years is expected to be drilled in applied medicine so that he will be fitted to engage in practice.

What are the advantages of each of these methods and what their mutual relations? It is frequently said that the didactic lecture should be discarded, that recitations are unnecessary and a waste of time, as the student can learn by reading without reciting; that the clinic to large classes is but a dramatic display, and that teaching should be done wholly to small sections and in the ward or in the laboratory. May it not be that there is something of good in each of these methods and that a too hasty discarding of the one or the other may be detrimental to the best interests of medical education?

If by recitation is meant merely the reciting from memory of certain allotted portions of a text-book, and if the teacher is but a timekeeper who records attendance and marks the student according to the nearness of his approach to repeating the order and wording of the approved text-book, then the teacher is a figurehead, the recitation a farce and an injury to teacher and pupil alike. The true recitation is a conference. The teacher not only listens and criticises, but he invites inquiry; he explains and expounds; he may talk much more than does the pupil; he does not hesitate to call attention to debatable statements in the text-books; he quotes other authorities; he incites his students to look up original articles; he is something far different from a recording clerk who marks percentages showing a student's ability to memorize. And the student under this method of teaching is not only acquiring facts, but is learning how to study. Many students do not know how to read and assimilate a medical article even though it is well written. They fail to put in their proper relations the facts of prime and of subordinate importance. Their conception of a disease is, therefore, a distorted one, its relation to other diseases is misty, the bearing of facts in physiology, pathology and therapeutics upon this disease and its clinical manifestations are poorly appreciated. When such students attempt to tell what they know their failings at once become apparent to themselves and to others. One often thinks he understands until he tries to put his knowledge into articulate or written words. Loose statements made in the recitation do not pass the muster of the critical instructor and the critical fellow-students. Exactness of knowledge and of expression is demanded, and the student makes but a few failures of this sort before he begins to change his habits of study and learns to read, think and express himself clearly and logically.

The proper place for the recitation is at the beginning of the junior year, when the study of the practical branches is first taken up. Before beginning the higher work of the senior year and the study of actual clinical cases there should be a general survey of the subject so that things may be seen in their proper relations, diseases may be grouped and differential diagnoses made understandingly. The study of practical medicine and surgery should not be begun with the oil-immersion lens, but with an objective of lower power and wider field. The recitation course carefully conducted, with properly fitted teacher, good text-books, classes or sections of no more than twenty-five gives this training that is necessary before the student enters upon the more advanced work.

Clinical work is in reality laboratory work. The ward is the laboratory, the patient and the instruments of precision the material; problems are here to be wrought out requiring the same powers of observation, the same collocation of facts, the same logical reasoning, the same precise demonstration, that are required in the laboratory of chemistry or pathology. Every argument elsewhere made for laboratory methods applies to the clinical method of teaching. The closer the student comes to his patient, the more he works out for himself the problem of disease confronting him in a given case, the more firmly fixed in his mind will be the facts thus learned and the better training has he had in independent work. The spirit of original research can easily be developed where students can have ward and bedside opportunities for the daily observation of patients and the comparison of different cases of the same disease, with free access to case records and a consulting library. Instruction in ward classes of six or seven, where the instructor quizzes and expounds, using as a text a concrete case already carefully studied by the members of the class and watched by them for days or even weeks, this is an ideal method of teaching the practical branches.

And there can be no question that this method of teaching more than any other benefits the instructor and keeps him stimulated to do his best. The case must be carefully studied by him before he can intelligently demonstrate it to a critical group of bright senior students. Loose statements will not be tolerated, nor can the teacher in the ward class, as is sometimes done in a clinic and in the arena, draw upon his imagination to fill in the missing symptoms or physical findings that enable him to make out a typical case of some disease. He must demonstrate not what the book says ought to be, but what is actually present.

But what of the amphitheater clinic? Is it wholly useless and to be discarded? As a means of training the student's own powers, of teaching him self-reliance and ability to reach conclusions and to produce independent work it can not be compared with the ward class just mentioned. But ward classes must be small and instructors must be many. From the nature of things in a large school these ward classes can not all be taught by the great physician or surgeon who stands at the head of his department, a man perhaps of world-wide fame, one from whom all the students desire to receive instruction and to whose teaching they are by right entitled. In order that all may learn of him his sections must be larger, fifty, a hundred or more; the amphitheater and not the ward must be the schoolroom. The man selected to give the large clinic should be a man of proven unusual ability in some one direction. He should be either a great operator, an original investigator, a physician of unusually wide experience, or a teacher who has unique ability in imparting knowledge. Such a man can teach a large audience. With a certain class of cases there is much to be learned by seeing the patient even from the distance of the benches of the amphitheater; such as a deformity of a fracture, its method of reduction, and the dressing applied. A tabetic can be well demonstrated as to gait, sensory and motor disturbances to a large class. Further, a class learns much from a careful review of the history of the case and from observing the methods of a good teacher in eliciting a history. The analysis of symptoms, the careful differential diagnosis, the discussion of prognosis are all valuable in the right hands.

The didactic lecturer who repeats the text-book to the class is a thing of the past, or should be. The didactic lecture should be limited to the taking up in detail of special topics, the work as a rule elective; subjects can thus be gone into more fully than is possible in a recitation course and more systematically than in the clinical work. Here, too, the same high-grade teacher is demanded as for the clinic, the man who by his own original work has something new to propound, or who has by an extended study of the work of others made himself master of the subject so that he can speak authoritatively, or who has an unusual ability in the presentation of a topic so that the crooked is made straight and the rough places plain for the student. Especially fitting for the didactic lecture is the discussion of recent work in the different branches of medicine, work that is not yet in the text-book, that is as yet in magazine and monograph. This is the proper field for the didactic lecturer. Merely to repeat the old familiar story that the student has read or can read in the text-book, that has been rehearsed in ward class and in clinic is to waste valuable time.

Recitations lay the foundation; they give the broad view, enabling things to be seen in their proper relations; the ward clinic trains the individual powers of observation, teaches independence of thought, gives manual training and skill in technique; the clinical lecture shows especially the methods of a master in his specialty; the didactic lecture takes up a topic exhaustively and brings the knowledge up to date.

There is a place for all these methods of teaching the practical branches, and where the work is properly divided, where instructors are not mere automatons, but wide-awake teachers; where the professors are experts as well as teachers, students should get a training enabling them to go out and become not only successful as practitioners of medicine, but successful as students in continuing their studies by themselves, their zeal in the pursuit of knowledge keeping them abreast of the times for many decades after they have been graduated and in spite of the cares and exactions of a busy practice.

CHANGES IN OUR MEDICAL SCHOOLS NECESSARY TO MEET MODERN CONDITIONS.

It is difficult to take the part of a prophet and it is thankless to take that of an adviser. There are, however, some changes which nearly all agree are coming to our medical schools, here earlier and there later, but eventually everywhere. The most important of these is the elective course. This system seems to be necessary on account of the enormous overgrowth of the curriculum and of the necessity of more thorough and more individual work. It gives the greatest possible liberty to the teachers and to the students alike. It eliminates by the law of the survival of the fittest the antiquated and the careless teachers. It makes the fictitious differences in professorial titles null and void, and it gives the active teacher immediate and effective recognition. It makes all changes in methods of study and institutional management easy.

The architecture of the medical school must be modified. Heretofore a single roof has been broad enough to house the medical college. It is not so any longer. There must be an anatomical institute, an institute of pathology as well as a hospital to make an effective medical school. One roof and even one location is not enough. Perhaps one faculty is not enough, but several faculties may be necessary to the coming medical education—one working in one part of the city or country and one in another—but all co-ordinated by the unifying and correcting action of the student's privilege of election under the guidance of his dean.

Extramural or non-resident teaching promises to increase greatly the facilities for education. In no way can adequate obstetric teaching be secured except by dividing the students among scattered lying-in hospitals and dispensaries. The same may be said of medicine and surgery, of the various specialties and of that intimate dependence between patient and student so necessary to his best interest and success. The medical school that shall achieve the widest success will be the one that allows its students the greatest liberty in selecting their teachers and places of study, still giving credit and ultimately a degree on evidence of work done.

In the coming medical school the social and esthetic life must be more fully satisfied. The buildings and furniture should take on dignity and beauty if they are to bring out the best in thinking men in the four years or more they are in use. There must be appropriateness and beauty in the lecture rooms and library, in the laboratories and assembly hall. The physical needs of the students must be met in the gymnasium and perhaps in a common dining-room or in clubhouses. Lectures laboratories and libraries are not enough to educate a medical profession which shall command the esteem and receive the economic tribute of modern society. Our medical students need all those helps to social life and esthetic culture which the university finds itself obliged in modern times to offer. Consider the activities of the university, and the needs of the medical school are counted. The club, the fraternity house and the common dining-hall; the dormitories, the gymnasium and the open playground; the esthetic decorations of the buildings, grounds, audience rooms and study rooms; the assembling of the broadest, most enthusiastic and most masterly scholars; the cultivation of all that is earnest, refined and devout in the student body—these and much more that these things stand for, are before the administrators of our medical schools for utilization.

Medical schools must become imbued with a more scientific and democratic spirit. Into the management of the school must come not only the influence of every member of the intramural and extramural faculty, but the student body must be well represented in the educational councils of the college. Only so can the dwarfing influence of vested interests and of antiquated ideals be overcome and the modern spirit of individual, active, life-imbuing education be given free course.

THE PLACE OF TEXT-BOOKS IN THE MEDICAL CURRICULUM.

It may be set down as a proposition from which there will be no dissent that every agency should be availed of that will contribute to the better comprehension and application of the science and art to which the medical student dedicates his life, and that will help to make him a more intelligent and a more practical physician. All education should have for its ultimate object not merely the imparting of knowledge, but even more, its successful and practical application. This end can be attained in divers ways, and while not a little depends upon the teacher and his methods, far more depends upon the pupil.

Discussion has recently waged about the part that the didactic lecture should play in the medical curriculum, and there has been a sort of frenzy with regard to the place that should be given to laboratory teaching. A sober judgment will decide that each of these has its own peculiar value, and that a better result will be secured from a judicious combination of the two than by any undue preponderance of the one over the other. Nor are all of the requirements yet fulfilled by these means. It is not possible in any course of medical instruction, however complete, to cover the entire field in all of its details, and this unavoidable deficiency must be made good by the use of text-books. This has a further advantage in stimulating intellectual activity and growth and developing intellectual independence, as well as in broadening the mental view and strengthening the mental grasp. As compared with the artist's picture, didactic, clinical and laboratory instruction may be considered as furnishing the sketch or outline, the details of which must be filled in by ample and judicious reading. It is a physiologic axiom that an unused organ atrophies and an unexercised faculty becomes enfeebled, and the brain and the intellect are better developed for being given a certain amount of pabulum to assimilate, in addition to that which it receives from the teacher, as it were, in a predigested form. The text-book, therefore, remains an important adjunct in the medical curriculum, its use in its place should be encouraged and we would commend especially the use of those that deal fully, comprehensively, and in a detailed manner with all the phases of the subject with which the student should be familiar, rather than the more concise and condensed presentations which may be committed to memory, and do not form a strong foundation upon which a worthy superstructure of knowledge may be built.

The several elements of a thorough system of medical education, including didactic lectures, clinical instruction and laboratory teaching, and the collateral use of text-books may be compared to the constituent factors of chromoscopy, or colored photography, of which if any one be wanting an uncolored picture results instead of the naturally-tinted reproduction.

WHAT DOES THE PRACTICE OF MEDICINE OFFER AS A LIFE WORK?

Under the present status of medicine in this country, what has medicine to offer as a life work? To the student deficient in preliminary training, and who must, in consequence, enter the only schools which will receive him, namely a poor one, the outlook is bad. Such a student begins the study of medicine with the idea of gaining a livelihood only. He has no conception of medicine as a science; no pleasure in the investigation of the many problems which confront the physician; only a half knowledge of the responsibilities of his calling; he can have no pleasure in scientific discussion and in fellowship with the best men of the profession; he will exist without social standing among the educated and cultured people of the community. He enters medicine to gain a livelihood, and he will find that his investment was a poor one.

To-day the status of medicine is such that he who would meet success must have a good preliminary education. The discipline of mind, the broad culture of a college education would be of great assistance to the student and to the practitioner. But if the student has not this training he should be able, as a minimum preparation, to pass the entrance examination of a good university or college. In addition, a reading knowledge of French and German is very essential to-day.

To a student so prepared who will spend at least four years in honest work in one of our best medical schools, and supplement the medical course with a service of one or two years on the house staff of a hospital, medicine offers much.

To a physician so educated, who is energetic, painstaking, and thorough in his work and whose integrity is unimpeachable, medicine offers more than the law, theology or politics. As a practitioner his life will be full of the most laborious and exhausting work. He will be much exposed to inclement weather, at all seasons of the year. His duties may interfere with his social and material pleasures. His sleep will be broken by calls to the suffering.

But to offset the discomforts which experience and fortitude lessen until he no longer considers them, he has the robust health and sturdy character which open-air exercise and the constant battle with and frequent mastery of the fell destroyer bring him. In the city his duties may fall in more pleasant lines of work, for a metropolitan practice is attended with less physical discomfort than is that of a country practice.

Wherever located, a good physician has no idle hours. Work—good, well-directed, persistent work, such as a properly educated physician knows how to do—will distinguish him from the indolent and ignorant in medicine, as it will in all walks of life. Medicine to-day offers opportunities for work as it never has in the past. For him who knows how, there are many problems to be worked out. The alleviation of human suffering, and the prolongation of life are subserved not alone by attendance upon the sick but by every measure which will enable us to discover the cause of and prevent disease. Much remains still to be investigated, and it lies within the province of the practitioner, quite as much as in the field of work of the pathologist, to make scientific observations and experiments. The intellectual life of such a man is full. He has the pleasure of constant intercourse with scientific, broad and cultured people. His work gives him but little time for the so-called pleasures of society. But he is a factor in the community, honored, respected and loved by all who know him. Such a man working unselfishly, doing good work because he is interested in it, and not because he expects a fee for it, will perhaps not become wealthy. He will, nevertheless, have a sufficient income to make a comfortable home and lay by enough to keep him and those dependent upon him when old age shall have come.

There never was a time in the history of the world, probably, when medicine gave as much promise to the student of a successful career, as now. But he who takes it up as a life vocation, from sordid motives, or who is poorly prepared and improperly educated, will meet defeat in competition with the man who is a physician because he wishes to benefit mankind. The true doctor is a nobleman. Carlyle said of the profession: "He that can abolish pain, relieve his fellow mortal from sickness, he is indisputably usefullest of all men. Him savage and civilized honor. As a lord chancellor, under one's horsehair wig, there might be misgivings; still more so, perhaps, as a lord primate, under one's cauliflower; but if I could heal disease I should say to all men and angels without fear, En Ecce!"

THE MEDICAL COLLEGE ASSOCIATIONS AND THEIR INFLUENCE ON HIGHER STANDARD OF MEDICAL EDUCATION.

The progress of medical education in the United States is one of the most remarkable phases of modern culture which has been observed during the past fifteen years. For the motives of this progress we are obliged to look in various directions: to the enormous increase in wealth which has marked our mastery over the physical resources of the earth through modern machinery: to the equally unexpected increase in our knowledge of diseases through the general scientific advancement, and lastly, to the coincident revival of a science or art of pedagogy. But aside from these general motives which underlie the progress of medicine as a whole, the course of progress in medical education and its most remarkable unanimity throughout the whole United States is in a peculiar measure due to the influence of the Association of American Medical Colleges, and its sister organization, the Southern Medical College Association. These bodies have kept the various rank and file of medical colleges in step and up to time. There have been leaders and scouts far in advance of the general body, but the great bulk of reputable colleges have been kept near these leaders by the unifying influence of these Associations, seconded by the hearty support of the various State Examining and Licensing Boards.

Through the influence of these pedagogic Associations, we have a gradually advancing standard for our professional education which is unparalleled by any similar growth in law, theology or schoolmastery and equaled only by that of dentistry and pharmacy. The preliminary requirements are now about those of the second year of the high school, but fortunately many, perhaps one-fourth of the eighty schools united in these bodies, are one or two years in advance of this minimum. The course of study now covers four years, and this is probably the maximum of required intramural study.

In attaining these ends the Associations have acted very cautiously and very firmly. These two objective points have been held firmly in view, but topics of general pedagogic interest have not been neglected as a reference to the proceedings of their meetings show.[1] The "Syllabus" was the work of three educational conferences and contained information and detailed instruction which saved much expensive and discouraging experimentation in the rapid change from a two-year to a four-year graded course. Later the establishment of medical libraries was encouraged and directed and the elective system was advocated. At each meeting numerous papers on medical pedagogy were introduced and the discussions were active, interesting and valuable. Delegates went home with added enthusiasm for better and more ideal work. Some radical and revolutionary papers in the early meetings of the Associations have been lived up to by the faculties of all the members and now the ideals of these iconoclasts are held as fundamental.

The work of these Associations has been so quiet and unpretentious, so full of argument and persuasion and so lacking in contention and compulsion that were it not for its depth and vigor it would attract little attention. A few of the leading colleges have never entered either Association. Three colleges have for one cause or another resigned, and two colleges have been expelled. Eight colleges have been denied membership. Out of 125 regular medical schools about 80 hold active membership in one Association or the other. There are now only five or six schools outside this membership which maintain a standard equal to the required minimum. It would seem as likely that all medical schools would find it to their advantage pedagogically and socially to unite into one helpful association as that literary colleges and even high schools have done so.

There is every evidence in the combined meetings of the two Medical College Associations which have been held during the last three years at Columbus, at Atlantic City and at St. Paul, and by the action taken in both Associations at their last meeting, that some union is likely to take place during the coming year. Nothing stands in the way except slight differences, which are rapidly passing away. The work of the Associations *hereafter will* be almost entirely pedagogic. Such great changes as medical education has suffered has been attended by much crudity and lack of system. The methods, purposes and motives of clinical and laboratory teaching and the general coördination of the whole curriculum is the work of much individual and collective labor. Let the Associations lay aside their differences and their legislative action and attend to this great problem on which so much of the honor and credit of our profession depends.

AN OVERCROWDED PROFESSION—THE CAUSE AND THE REMEDY.

We have in the past called attention to the overcrowded state of the profession in this country and the prospects for the future. It is not difficult to name a cause for this evil; it is chiefly to be looked for in the multiplication of facilities for medical education of a certain sort, and to the ambitious and advertising proclivities of *a certain portion* of the profession. For many years in the past there has been a steady multiplication of medical colleges, organized to meet a felt want —not of the medical profession—but of the founders. Articles of incorporation are easily and cheaply gotten, and with a little investment the new institution is launched. The result is not only an oversupply of diplomaed graduates, but the usual inverse ratio of quantity and quality. The highways and byways are raked for students; the preliminary requirements are nominal in the strictest sense; and the graduation requirements too often necessarily follow the same rule. The instruction is mediocre, the clinical facilities poor, but the institution goes its way and flourishes; the faculty gets an advertisement and a growing clientele of half-fledged doctors, all the readier by reason of their insufficient mental and professional acquirements to furnish business for their revered professors in the way of consultations, etc., while the profession as a whole and the public suffer in proportion. We have cheapened the medical profession by making it too common and lowering its standards, if not actually as compared with the past, at least relatively as compared with the scientific advances of the day. It is true that our best is in no way inferior to the best of any land, but our average is not what it should be, and our lowest is infinitely below what ought to be endured.

---

[1] Bulletin of the American Academy of Medicine, 1890-1901, inclusive; The Journal, 1889, et seq.

This is what has been in the past and what we have not yet fully outgrown. That there are agencies and influences at work for the better is undeniable and their effects are already visible. The medical practice acts that exist now in the great majority of states are to be counted among these, and this we owe to the organized effort of the profession which has latterly become, more than ever before, alive to its own interests and that of the public in this regard. There is much yet to be done in this line; they must be made more universal and more uniform, and as regards the latter there must be no leveling down. If we wish to make ourselves respected we must make ourselves respectable—a truism too much overlooked in the past. Then, there should be a self-denying ordinance adopted by the profession generally and the title of professor be no longer an indication of stockholding in a corporation for profit, direct or indirect, but on the other hand a valid evidence of acquirements that have received the endorsement of public and professional appreciation. With this advance in requirements for practice there should be a marked and general stiffening up of the preliminary educational requirements; the reform must start at the fountain head if it is to be what is imperatively required. The control of entrance examinations must be put out of the hands of the medical college faculties, which should be delivered from the temptation of augmenting their student lists. There should be in each state a non-political authority, independent of the colleges, to regulate the requirements for admission to the medical course as well as to medical practice. This is already the rule in some states. Until this system is universally and efficiently applied we still shall have much that should not be.

The prospect, however, is brightening, and there is no call at present for any very pessimistic outlook for the future if we can only sacrifice self-interest and work together for the common good. Of the 160, more or less, existing medical colleges in this country and their thousands of professors and other medical attachés, there are a large number that can profitably be spared. It is to be hoped that with higher standards universally applied their number will soon be adequately reduced, and that only the fittest will survive.

WHAT SHOULD GOVERN THE STUDENT IN THE SELECTION OF A MEDICAL SCHOOL?

Young men and women entering on the study of medicine may be divided into two general classes. In the first are those who look upon the practice of medicine as a calling in which there must be self-sacrifice, hard work, constant care, and great responsibility. These are ambitious to prepare themselves to the best of their ability for the duties they assume. Their motives are high and noble. In the second class, happily getting smaller each year, are those who look upon the practice of medicine as a calling in which one can make a living without effort and into which entrance is easy. The only ambition of this class is to get a degree with the smallest outlay of time, energy, and money. To these we have no advice to give.

It is of the highest importance that the young man entering on the study of medicine should select a school which will best fit him for his work. The four years he spends in getting his degree will prove to be the most important four years of his life. If the student spends these four years in a medical college whose requirements for entrance are low, whose teachers are mediocre, whose facilities for instruction are poor, whose clinical advantages are inferior, there are nine chances to one that he will go through life a "poor doctor" in more ways than one. One of the laws of physics as applied to hydraulics is that water never rises higher than its source.

The first two years of the medical student's life are more important than the two later years, for in them the scientific foundation is laid. A practitioner must study the practical branches of medicine and surgery all his life and he will obtain clinical experience from every case which he treats, but the fundamental subjects are rarely studied after leaving college. It therefore behooves the student seeking a school to select one that is thoroughly equipped and capable of giving him the best possible instruction in the fundamental branches. Too many make the mistake of selecting for the first two years a school poorly equipped with teachers, with laboratory facilities, etc., with the intention of going to one of the leading colleges for the two later years. This is often done on account of ecomomy, but it is very poor economy. Better wait and save and then start right, for the extra investment thus made will bring satisfactory returns through life.

The better colleges have good laboratory facilities in connection with every fundamental branch, such as anatomy, histology, embryology, pharmacology, bacteriology, etc. They generously equip laboratories with necessary instruments for thorough individual instruction in all these branches. A student must often judge of the worth of an institution by personally examining its facilities for teaching these branches, for sometimes the catalogue will not give him reliable information in this regard.

In the last two years the practical side should be considered: that which applies to the everyday work which will fall to the young physician when he enters on his practice. To do good practical teaching here, clinical material is necessary. Without these no school can fit the young man in the final two years of his medical studies no matter what facilities it may have aside from them.

Laboratory and clinical facilities being the fundamental necessities, there will come other advantages that are not to be entirely slighted. For instance, the school that has connected with it men of repute, men who have made a name for themselves through investigations and scientific medical work, are to be considered before the schools which have no such men connected with the teaching faculty. While it does not follow that these names in themselves will necessarily make good students—and no one should aim to shine merely by reflected light from his alma mater—there is always an advantage in hearing instruction directly from the recognized masters in the profession. Such men, moreover, are generally appreciative of genuine interest on the part of students and will often give their special aid and attention in such cases.

While every systematic educational course has for its chief end to fit the student to use his mind, in medicine, as in every technical branch, a man must be trained to do as well as to think. Hence, the advantage of hospital training, the "practical year," the importance of which has been so emphasized by Ziemssen and Von Jaksch. Every student should look forward to an interneship as a final crowning of his medical course, and since this is not attainable by all, it is well for him to select a school in which the clinical instruction includes practical hospital work for every student as a dresser or clinical aid. Without some practical experience of this kind the conscientious newly launched practitioner will often feel almost overwhelmed by his responsibilities. The old preceptorial system met this need in a way, though otherwise lacking, the modern medical school in the recent past, if not at present, has too often worked ill in the opposite way by sending out graduates without adequate training under skilled oversight.

It must not be imagined that the good schools are only to be found in the large cities. There are institutions scattered all over the country, whose facilities are excellent, whose teachers are above the average, and who strive to give their students a thorough practical education. Such schools may have moderately small clinical advantages, compared to some in the larger cities; but this apparent lack is made up by there being fewer students to be subdivided into classes for personal instruction and for clinical work at close range. The medical department of some of our state universities, although located in small towns, are splendidly equipped for the first two years' work, even though the same institutions may not be well supplied with clinical advantages. The school, however, which creates in the young man an ambition to study, a craving for knowledge and a desire to keep up the work after he leaves the college, is the one that is to be considered as foremost. Such schools turn out men who become leaders in the profession, and their greatness reflects credit on their alma mater. A school with such credits is a safe one to select.

THE CASE METHOD OF TEACHING.

The case method of teaching which has been incidentally mentioned elsewhere in this issue, while originally elaborated in legal institutions, has also been utilized to advantage in medical instruction. In a crude form it has long been in use; the practice of demanding bedside diagnosis, etc., at clinics is an old one and has been employed by many teachers. The introduction of the fully-elaborated method at the University of Pennsylvania occurred some two years ago, and the details, as followed out in that institution, are given by Frazier in the University *Medical Bulletin* for September.

Each student is given a manifold copy of the complete clinical data of a case in the hospital records, including family history, physical examination, antecedents, blood, urine, sputum, etc., examinations as well as the full history of the disease. He is instructed to prepare a report from these facts including diagnosis, prognosis and treatment; in some cases only one or two of these may be required; in others, special attention is called to the diagnosis, prognosis or treatment. No conclusions are accepted or given credit for unless based on logical reasoning from the facts given. These papers are distributed each Saturday and a report required on the following Saturday. A week later the instructor analyzes the reports before the class, points out their errors and omissions, states what further examination might be conducted to elucidate the case, and gives the subsequent history, results of treatment, etc., as they occurred. As a rule, typical cases are not selected, but those that give the student some exercise of judgment in his diagnosis and they are so chosen as to work into a systematic scheme embracing instances of affections of each important class. Dr. Frazier finds the methods of value in developing the power of discrimination, educating the judgment, encouraging research into authorities, and widening the reading of the student. He also finds that it especially arouses enthusiasm and interest, a point the importance of which is not to be underrated.

It is evident that a plan that presents, as this does, cases as they will occur in actual practice must be more interesting than purely impersonal facts or dry enumeration of symptoms. Instruction in case-taking, which is at least indirectly involved in this method, is also important and perhaps it could not be better given. Though the observations here are ready-made, so to speak, they indicate what ought to be observed and it may be that this will prove to be one of the best adjuncts in the education of the faculties of medical observation.

THE PREPARATION FOR THE MEDICAL COURSE.

When the nation was younger, and the supply of physicians was small, and the demands of a rapidly increasing population for medical attention large, two years was considered sufficient time to equip the raw recruit for the performance of his professional work. The course of instruction at the medical school was, however, preceded and ably supplemented by association with an active practitioner as preceptor, and whose tutelage often constituted a most valuable and highly important factor in the education of the young physician.

This method, in conjunction in some instances with post-graduate study in foreign countries, resulted in a race of physicians who understood especially the art of medicine, and whose labors and results entitle them to the highest meed of respect praise and commendation. As time went on, however, the supply of medical men became ample, and eventually excessive, while at the same time the field of medical knowledge became wider and more difficult of encompassment, so that a fuller measure of learning and a higher degree of proficiency were required of the medical graduate. Thus, a period of study covering three years was declared insufficient, and the present course of four years was established.

With these advances, and by reason of the requirements growing out of them, it became necessary to make entrance upon the study of medicine conditional upon the possession of certain intellectual and scientific qualifications. It thus comes about that in a small, but growing number of medical schools, the post-session of a Bachelor's degree as an indication of adequate preparation has been made the prerequisite of matriculation. Now, it has been found that by this course the graduate of medicine is pretty well on in life when he receives his professional degree, and it is contended, as it seems to us reasonably, that by making a part of the work of the last collegiate year preparatory to that of the medical course at least one year of this long period of study could be saved the student, without detriment either to himself or to the profession of medicine. Elementary work should have no place in the curriculum of the medical school proper, and the student should be thoroughly grounded in such branches as botany, biology, chemistry, physics, etc., apart from the possession of a general education before he is permitted to enter the medical school.

Other things being equal, the best and most broadly educated men and women will make the best and most successful medical students and practitioners. But it is evident that a certain harmonization in our general educational scheme is necessary to give it a unity and a continuity that it has not in the past possessed, but in which, evidence is now accumulating, a good beginning has already been made.

THE TEACHING OF ANESTHESIA IN MEDICAL SCHOOLS.

The contempt bred by familiarity is exhibited by the comparative indifference to danger displayed in the practice of anesthesia. The gravity of narcosis by ether, chloroform, nitrous oxid, ethyl bromid, etc., is not always fully appreciated, although in order to effect the desired result the patient is necessarily brought in varyingly dangerous proximity to the point of dissolution. In view of these facts no special argument should be required to make clear the wisdom, nay, the urgency, of including instruction in both the practice and the principles of anesthesia as an essential part of the medical curriculum. In this spirit there should be given a series of lectures dealing with the physiologic actions and the toxic effects of the various anesthetics employed, and the means for combating the latter should they arise, and laying down the indications for and against individual anesthetics in the presence of varying disturbing factors, together with a demonstration of the various forms of apparatus and their mode of employment, as well as the measures to be taken for resuscitation; and, finally, the student should be required to witness a certain number of narcotizations, and under skilled supervision participate directly in a number of others. As things are at present, the graduate must gain his own experience either in private or in hospital practice, and while fortunately this course is in the overwhelming majority of cases unattended with serious results, these may under certain circumstances be most disastrous. A few hospitals have specially trained anesthetists under whose supervision narcosis is practiced, and it would be a step in advance if all institutions of this character were similarly officered. For these reasons it must be obvious that the practical teaching of anesthesia in the medical schools is an end much to be desired.

THE USE AND ABUSE OF LABORATORIES.

It is a truism that every agency capable of doing good is in equal degree capable of doing harm. The difference resides in the mode of application, or, as with drugs, in the dose. This statement is applicable to laboratory work as it exists in medical education. Knowledge is complex, and isolated facts often have little value, but when correlated with others their importance may become manifest. So the teachings of the laboratory, which can not be considered as final, if not correlated with those of clinical observation and of reading, may be barren and even lead to misconception. Demonstrative instruction is the most impressive, and in so far as the work of the laboratory is directed to a demonstration of normal and morbid processes will it be of practical value. The laboratory student further acquires or develops a spirit of investigation which will stand him in good stead in the scientific study of cases, with the result that his diagnoses will be the more accurate and his treatment the best adapted to the individual case and the most successful in result.

MEDICAL EDUCATION TO-DAY FAR BETTER THAN IN THE PAST.

Unsatisfactory as the condition of medical education in this country has been in the past and many as are the desiderata of the present time, there is ample reason for encouragement. Twenty-eight years ago there was but a single medical school in the country with more than a two-year course, and few even fifteen or eighteen years ago. Now, as shown by tables elsewhere, there are but two in the country that do not demand, or at least profess to demand, four years' attendance before graduation, and of these two, one proposes to adopt the four-year course after 1902. It is true that there may be evasions of the rule and that some institutions may profess more than in fact they perform, but these must be rare exceptions among those recognized as reputable colleges, if they really exist at all. Medical education in this country is a different thing from what it was two decades ago, and there is every prospect that the progress of the recent past will be continued in the future.

Death of President McKinley

Without reproach in life or fear in death, William McKinley, Christian knight and twenty-fifth President of the United States, has passed away.

A fateful fortnight is gliding into its place in history. A cruel assault; a gallant and blameless man stricken; a day or so of gloom and the hot wrath of millions; a day or so of wild joy, with the mirage of health and service luring on; a day or so of fear and foreboding; a smile, a gasp, a woman yearning by; and they who thought to change the rule of man by force began to feel, and long will feel, the dagger of their new dispensation press hard and cold against themselves.

The solemn thunder of the funereal car has ceased; ceased, too, has the sonorous tribute of the minute gun, and the first flood of neighbors' silent tears. The dead, who knowingly wronged no man, is in his grave; and the Nation that is mightier, juster, better for his having lived, sobs "Amen," faces front and marches on.

Few words and simple speech best voice the dead man's requiem. William McKinley had those things and did those things that mark a great man. No extravagant eulogy nor intoxicating rhetoric should cloud or confuse our judgment of the man as he was in his heart. Years ago, when he climbed the first steps of his broad career, he was already an average American. He knew, had sacrificed for, and was helping to get what his country needed to make it one, to make it strong, to make it great among the nations. To the knowledge and deeds of the apprenticeship of this average American came, in richer form, in the harvest years of his mastery, tact, prudence, kindliness, brotherly love, and an abiding purpose and courage to know and do the will of his people and his God. Of such are statesmen whom nations trust and love.

In the category of the great we may write him who sleeps in glorious peace beneath the martyr's palm. He has led a pure life and shone a peerless husband. He has taken up arms for his country. He has put away bitterness from within his party. He has led his countrymen to the conquering stand of a nation that makes, sells, and lends, rather than that of one that begs, borrows, and defaults. He has preached brotherhood and pursued it, and from his touch no wounds smart. He has made war only when he must, and when he has ceased he finds no foe. Triumph has brought new lands and problems of rule without precedent. With his last breath he has warned his brethren that a nation can not live in, upon, and for itself alone; and, hence, for new conditions he has proclaimed new policies. As a man he has been the American's ideal, and higher there is none; as a statesman he has been trustworthy, if not aggressive in initiative. We know he was good; let us err, if err we do, upon the right side and also call him great.

Meantime trade, the Nation's life, halts not, nor falters the Nation's trust in itself and form of government. To the widow of the beloved dead goes out sympathy deep and significant in its universality. Continents and isles mourn with us. Little that has followed in the train of the martyr's fall would we have had unsaid or undone. "God's in His heaven; all's well with the world."

A great man that was loved has fallen. In the crises of time primitive virtues revive and rule. An ancient Roman has passed from among us. Of such they sang:

"Integer vitae, scelerisque purus."

THE WOUNDS OF PRESIDENTS GARFIELD AND M'KINLEY.

Naturally enough, laymen, the lay press and many medical men have compared the wounds of President Garfield and President McKinley since the latter was so brutally murdered on September 6. There is, however, from a surgical standpoint, absolutely nothing similar in the wounds of these illustrious patients. The wound in President Garfield's arm was a flesh wound, as was the one in President McKinley's breast, and can, therefore, be dismissed, as having no bearing upon the result.

The second and fatal wound of President Garfield was fired from the rear, and was made by a 44-caliber bullet, fired from a British bulldog revolver. The result of the autopsy showed how completely the distinguished surgeons in attendance had been deceived as to the real nature of the injury; for instead of passing through the liver, transversing the abdominal cavity, and lodging in the anterior wall, as was thought, the wound was entirely extra-peritoneal. The records of the autopsy leave no room for doubt, for the postmortem was made by the President's eight surgeons themselves and the report signed by all. The official announcement of its results said:

"It was found that the ball after fracturing the right eleventh rib, had passed through the spinal column in front of the spinal canal, fracturing the body of the first lumbar vertebra, driving a number of small fragments of bone into the adjacent soft parts and lodging below the pancreas, about two inches and a half to the left of the spine and behind the peritoneum, where it had become completely encysted.

"The immediate cause of death was secondary hemorrhage from one of the mesenteric arteries adjoining the track of the ball, the blood rupturing the peritoneum and nearly a pint escaping into the abdominal cavity. An abscess cavity, six inches by four in dimensions, was found in the vicinity of the gall-bladder, between the liver and the transverse colon, which were strongly adherent. It did not involve the substance of the liver, and no communication was found between it and the wound. A long suppurating channel extended from the external wound between the loin muscles and the right kidney *almost to the groin. This channel, now known to be due to the burrowing of pus from the wound, was supposed during life to be the track of the ball.*"

While the immediate cause of President Garfield's death is said to have been secondary hemorrhage, such a result was due to a sloughing blood vessel, one of the usual terminations of septic cases. President Garfield had pyemia. His symptoms indicated it; the autopsy proved it. The question has been asked thousands of times during the past few days on account of the favorable bulletins reporting President McKinley's condition, if his distinguished predecessor in office could have been saved by modern surgery. Possibly he could; though it is optimistic and presuming too much to say that such a result would have been, as has so often been said in the recent past, reasonably certain.

A 44-caliber bullet fracturing the rib, then crashing through the body of a lumbar vertebra and driving a number of fragments into the soft parts, thence lodging behind the pancreas, makes a wound and condition not to be despised by even the boldest and deftest of modern operators. Moreover, President Garfield was a very stout man, which would have increased the difficulties. Were such a bullet promptly located to-day by the X-rays, any experienced and conscientious surgeon would hesitate as to his course. If he elected to remove the bullet, again he would be embarrassed to know whether it were best to choose the anterior or posterior route. A laminectomy is a comparatively simple operation in a thin subject; but to reach the body of a vertebra, much less go anterior to it, as would have been necessary to have recovered the ball and removed the spiculæ of bone driven forward by it, in a patient of President Garfield's build, would have taxed both the anatomical knowledge and surgical daring of the greatest of his surgeons, the gifted Agnew. If the anterior route were chosen, one has only to think of the important vessels and nerves superimposed on the bullet, and were almost in contact with it. By either, anterior or posterior route, the danger from hemorrhage would of necessity have been great.

Again, can we say that pyemia has been banished from surgery? Certainly not; rare it is, to be sure, at present; but President Garfield had just the kind of a wound that is to-day, with all our much-vaunted aseptic and antiseptic surgery, difficult to treat and uncertain in its results. Compound fractures, especially of soft bones such as vertebræ and ribs in inaccessible situations, constitute the most fertile cause of pyemia to-day. Moreover, pyemia following bone injuries is admittedly more fatal than pyemia following injury to soft parts. Therefore, there should not have been at the time so much criticism of those brave and skilful men who labored incessantly for nearly three months to save their distinguished patient. Now, that the matter is up again for discussion, it should be the duty of medical men, particularly, to set matters and history right, and not encourage the belief, so very general, that President Garfield's wound, fatal in 1881, would be trivial to-day. It was fatal in 1881 and would probably be fatal in 1901. Mistakes may have been made; but even if they had not been, there is little likelihood that the Nation would have been spared the poignant grief at the brilliant Garfield's untimely taking off and the disgrace of a second murdered president.

President McKinley was shot from the front with a 32-caliber ball entering five inches below the left nipple and one and one-half inches to the left of the median line. It traversed the abdominal cavity, perforating both anterior and posterior walls of the stomach, the opening in the former being small, the one in the latter large and ragged—just the character of wound usually made by a pistol ball at very close range. After thorough closure of the gastric wounds, from which there had been some extravasation, a careful search was made for other possible injuries. None were discovered, and the surgeons were reasonably certain that the bullet had found lodgment in the muscles of the back. The abdominal cavity was freely irrigated with normal salt solution, and closed without drainage by through-and-through sutures of silkworm gut. A small piece of clothing—presumably from the undershirt—had been carried in by the bullet; but was, we understand from the statements given out, found in the abdominal portion of the wound.

In exploring the abdomen, Dr. Mann acted wisely in enlarging the original wound, rather than performing median section. Irrigation of the cavity is to be distinctly commended; likewise the use of interrupted sutures, saving as they do the loss of time, and facilitating to no inconsiderable degree, when rightly placed, drainage—two very important elements in the President's condition.

Whether or not provision should have been made for further drainage depends entirely upon the existing conditions, and they were best judged by the distinguished surgeons charged with the responsibility of saving, if possible, the most precious life in the world. The profession has had the utmost confidence in each of them; the Nation has shown its gratitude for the promptness with which their awful responsibility was assumed, and the thoroughness and ability with which it was carried out.

If the operation had been hurried there might be some reason to feel that possibly each step of it could not have been considered as judiciously as the occasion demanded. Such was not the case; the President was under ether an hour and a half and was in such good condition all the time that there was no demand made upon the operator for haste. The autopsy shows that good judgment was shown in not prolonging search for the ball.

In declining to use the X-rays subsequently, notwithstanding the general anxiety as to the ball's exact location, the surgeons were judiciously passive and following the teachings of the greatest of military surgeons. A second anesthesia and operation for the extraction of a 32-caliber bullet in the muscles of the back would, under the circumstances, have been not only injudicious, but censurable. One can not forbear to say at this time that the Roentgen rays are not an unmixed blessing, as death has followed operations for encysted bullets that were doing no harm at the time of their removal. One of a yielding nature may be induced to act against his better judgment, on account of the anxiety and importunings of patient and friends, always greater than they should be, but due to an exaggerated importance given by laymen to the "ball" and its recovery. Those who knew the President's surgeons personally have felt assured from the first that no precipitate action would be taken to meet a danger largely chimerical in its nature, whilst urgent, portentous, awful problems were pressing forward for solution.

What were the probabilities when it was known that President McKinley, a man 58 years old, with a weak heart, had sustained a penetrating wound of the abdomen? Death, undoubtedly, was the likelier issue. When, however, the details of the operation were given Saturday morning, and it was recalled that the President was shot at 4:30 in the afternoon, when his stomach was presumably empty, or nearly so, more than a modicum of comfort and hope was felt by a stricken Nation. The operation had been promptly done; it had been thoroughly well done; it had been done by the best exponents of modern surgery. The incidents of the first, second, and third days—the period of greatest danger—were distinctly favorable to the President's recovery, though his abnormally high pulse-rate caused uneasiness. It had all along been out of proportion to the temperature and respirations, but it was explained as being usual with him. The fourth and fifth days served only to fortify his surgeons in the opinion already expressed that he would recover. It seemed that he would and that he should get well; yet there were still dangers ahead to which a too hopeful and impulsive people were oblivious. They came on the sixth day and had practically ended this magnificent life in another twenty-four hours!

Of the exact causes leading to the change which resulted in death, we shall know more when the full report of the autopsy is published. This will be after cultures have been made and a histological examination has been completed. When this full scientific report is officially given out it will be time to discuss the cause which led to the necrotic condition found at the autopsy but not before. Until then at least there should be no criticism of the management of the case and full credence should be given to the official bulletins signed by the attending surgeons and to these only. The absence from Buffalo of the nearest relatives of President McKinley at the time of the unfavorable change showed plainly enough that they had left him doing so well that only recovery was thought of. The public were fairly and candidly treated from beginning to end. The unexpected happened. While the Nation grieves as it has never done before on account of the pathetic and unusual circumstances surrounding President McKinley's death, we should give full credit and honor to the heroic surgeons who, with a moment's notice, gave to the President of the United States everything that science had to offer. As we think so will the lay press, his countrymen and the world.

The criticisms of 1881 are not, we hope, to be repeated. The courageous action of Dr. Mann and his associates in performing an immediate laparotomy is more to be commended now than it would have been three years ago; for since our war with Spain and the Anglo-Boer war in South Africa non-intervention in gunshot wounds of the abdomen has been the rule in military surgery. A masterly inactivity in such injuries has had the weighty endorsement of Senn, Nancrede, Lagarde, Parker, and other surgeons of prominence in our army, and Treves, Sir William MacCormac, and others of the English surgical staff. Many of the *supposed* perforating wounds of the abdominal cavity in the American and English armies recovered without operation. A rule which is applicable and proper in military surgery can not always be accepted in civil practice. The wounds are different; the facilities and environments are different. The modern rifle-ball is small, conical, .303 of an inch in caliber, of great velocity, and cuts like a knife. Such a wound occurring in soldiers with comparatively empty gastro-intestinal tracts—brought about by starvation and diarrhea, common conditions in soldiers—might be recovered from; whereas, a pistol ball which is usually larger, rounder and of less velocity, makes a greater and more ragged opening, through which extravasation from any of the hollow viscera injured would almost surely take place. It is also far more likely to carry in clothing and other foreign material which would have a tendency to cause irritation and even sepsis.

It is of interest to recall the fact that the first successful laparotomy for a shot wound of the abdomen was a pistol shot wound of the stomach, successfully operated on by Kocher of Berne in 1884. Kinloch of South Carolina had previously (1882) unsuccessfully operated on a case of multiple wounds of the small intestines. The first successful laparotomy for an intestinal wound was by W. T. Bull in 1884.

While the prompt, commendable and praiseworthy surgery at Buffalo did not result as it deserved to, in the recovery of President McKinley, it has placed the treatment of gunshot wounds of the abdomen upon a firmer and better footing than ever before; just at a time, too, when it had suffered a partial eclipse, on account of the teachings of military surgeons; teachings which are right for the battlefield and emergency hospitals, with their poor equipment for abdominal work, but wrong when one can have the benefit of timely aid from a competent abdominal surgeon in a well-equipped modern hospital.

If in dying, this great and good man has advanced the cause of surgery, and has been the means of exterminating anarchy in the country he loved and served so well, then he will not have suffered and died in vain!

NO DISAGREEMENT AMONG THOSE WHO ATTENDED PRESIDENT McKINLEY.

The undersigned surgeons and physicians who were in attendance on the late President McKinley have had their attention called to certain sensational statements recently published in the daily papers, and particularly one New York paper, indicating dissensions and mutual recriminations among them.

We desire to say to the press and public, once for all, that every such publication and all alleged interviews with any of us containing criticism of one another or of any of our associates are false, and are nothing but scandal-mongering.

We say again that there was never a serious disagreement among the professional attendants as to any of the symptoms or as to the treatment of the case or as to the bulletins which were issued. A very unusual harmony of opinion and action prevailed all through the case.

The unfortunate result could not have been foreseen before the unfavorable symptoms declared themselves late on the sixth day and could not have been prevented by any human agency.

Pending the completion and publication of the official reports of the postmortem examiners and attending staff, we shall refuse to make any further statements for publication and alleged interviews with any of us may be known to be fictitious. MATTHEW D. MANN; ROSWELL PARK; HERMAN MYNTER; EUGENE WASDIN; CHARLES G. STOCKTON.

Buffalo, Sept. 17.

MANAGEMENT OF THE CASE OF PRESIDENT M'KINLEY.

It is not unusual for physicians or surgeons to make mistakes in judgment and therefore it often occurs, when a case is ended and death supervenes, that those who have been in attendance look back and wish they had done a little differently here or there. Such things are liable to occur until the time comes when human judgment is infallible. But reviewing the facts of President McKinley's case from the beginning, so far as they have come to us from reliable sources, and supplementing the reports by all that we can reasonably surmise, we see no reason for the slightest criticism of the surgical and medical treatment. Whatever medical science could do at the present time was apparently done. The administration of a minute quantity of solid food on Wednesday, which has been criticised, appears to us to have been perfectly justifiable and that it could have had no ill effect is sufficiently proven by the autopsy. From the prompt acceptance of responsibility by the surgeons at the beginning to the last sad phase there is nothing in the conduct of the case that calls for self-reproach on their part or justifies criticism of their course by others. It shows more prominently than many cases our limitations and is in this way humiliating, but this does not in any way detract from the services of those who did all that human wisdom and ability could do.

When on Friday morning announcement was made of the relapse which had taken place, those in charge were criticised for the supposed optimistic reports that had been circulated. Before criticising, however, it would be well to inquire whether criticism was just. Physicians who have been interviewed know that the report of what they say is more likely than not to be incorrectly given to the public. Those connected with this case have disclaimed responsibility for what appeared in the newspapers both before and since the President's death. Our reporter called on three of them for information for this journal and they justly refused to make any statement outside of the official bulletins. If they were expressing opinions to the newspaper reporters, they certainly would not have held them back from the medical journals. Dr. Roswell Park denied on Thursday morning, the day before the relapse, a previous newspaper report crediting him with having expressed a belief in the certain recovery of the President.

Others of the Buffalo surgeons also have repeatedly denied any responsibility for statements attributed to them in the papers. Drs. Mann and Park, we are authoritatively informed, have stated that at no time were they free from anxiety, and it is probable that the same can be said of the others, with possibly one exception.

The surgeons should be held responsible for the official bulletins which they signed and for these only. These show no utterance of absolute confidence in recovery. Rather, the continued high pulse was indicative to members of the profession that all was not as it should be. We therefore see no reason for criticism on this point. When the facts are made known it will probably be found that some symptoms were present that were not what might have been desired, but it would have been just as unwise to have given publicity to this indication of possible danger as to give the optimistic opinions that were unjustly credited to some of the surgeons. The editorial opinion expressed in the last issue of The Journal regarding the official and other statements of the attending surgeons is still held as the only one justified by the facts.

When the full official report of the autopsy is published comments may be made regarding the gangrenous condition found in the track of the bullet. It would be merely theorizing to discuss the subject before the bacteriological and the histological examination has been made and the findings published.

THE SHOOTING OF THE PRESIDENT.

(From our Correspondent.)

Buffalo, N. Y., September 17, 1901.

The feeling of security for the recovery of the illustrious patient which the attending surgeons had was of only brief duration. From the time of operation the pulse was rapid and gave great concern to the attendants. This was at first supposed to be due to the shock from the wound and operation, especially when it was seen that the great sympathetic nervous system and its solar plexus was in the line of the track of the second bullet. The continuance of the high pulse, however, compelled the discarding of this theory. The question of peritoneal sepsis then arose; but there was no abdominal tenderness, no meteorism and no muscular retraction; as peristalsis was present, as the temperature fell instead of rising, and the pulse kept high, and as, furthermore, the examination of the blood made by Dr. Wasdin showed no leucocytosis, this cause was excluded.

During Tuesday of last week it was noted that the nutritive enemata gave the President a good deal of discomfort and were not retained. Broths were, therefore, ordered to be given in small amounts by the mouth, and on the following day a bit of toast was given. The bowels had not moved on that day and as the heart action still remained unsatisfactory it was thought expedient by the surgeons in charge to call Dr. Charles G. Stockton in consultation.

The question next arose whether the high pulse might not be dependent on intestinal toxemia. A considerable amount of indican was found on examination of the urine, but it diminished greatly when, as the result of cathartics, several evacuations had occurred. Nevertheless the high pulse continued. The increasing weakness during Wednesday night and Thursday resulted in the calling of Drs. William W. Johnson of Washington, D. C., and Edward G. Janeway of New York City, in consultation.

Despite heart stimulants, digitalis, adrenalin, normal salt transfusion and oxygen inhalations, the heart's action became weaker and weaker, and because there was no reaction from all the stimulation, the President's condition became one of utter hopelessness. It was expected that he would die during Friday but he survived until 2:15 Saturday morning.

He suffered little pain, and his sturdy faith, courage and bravery continued to the end. Dr. Mynter says of him: "The fortitude, courage, cheerfulness, and gentle consideration toward all his attendants, the doctors, nurses and orderlies, was remarkable. The martyred President won the love affection and admiration of everyone who had the privilege of administering to his wants during those seven sad days."

THE POSTMORTEM EXAMINATION.

The autopsy was held at the Milburn house at 11 a. m., Saturday, September 14. The examination was made by Dr. Harvey R. Gaylord, of the New York State Cancer Laboratory, assisted by Dr. Herman G. Matzinger, professor of clinical pathology in the University of Buffalo. Major W. B. Kendall, surgeon U. S. A., Fort Porter, and Captain Edward L. Munson, assistant surgeon, U. S. A., of the Brigade Hospital represented the

Government. Drs. Mann, Mynter, Park, Wasdin, Rixey, Stockton, Janeway, Johnson, Cary, and Baer, and the District Attorney and a stenographer were also present.

The following were the findings of the autopsy: Rigor mortis. The wound on the chest consisted of a blackish-yellow abrasion, surrounded by a large zone of discoloration. The point of impact of the first bullet was between the second and third ribs, just at the right edge of the sternum. Incision through the tissues at this point showed a moderate blood infiltration, extending to the muscle, and immediately under the point of impact, a small cavity was seen, the size of a pea, where the skin had been torn away from the subcutaneous tissue.

On opening the abdomen, the wall of which was two and one-half or three inches in thickness, the omentum was found adherent all around the wound of operation. This wound was five inches long, extended down to the muscle and was healthy in appearance, no gangrene being present. The omentum was healthy and no signs of peritonitis were evident. The intestines were smooth and shiny without adhesions or exudate. The mesentery of the transverse colon was adherent to the stomach wound. On loosening these adhesions, the sutures of the wounds of the anterior and posterior walls of the stomach were found tight and in place, allowing no leakage.

Around the sutures, however, there was a zone of total gangrene of the wall of the stomach about two inches in diameter and ready to slough. A similar gangrenous condition was found on the opposing surface and adherent mesentery of the transverse colon, the necrosis extending into the head of the pancreas.

From the wound in the posterior wall of the stomach it was found that the bullet passed through the transverse mesocolon, near its attachment, thence through the posterior layer of peritoneum, cutting a groove into the upper end of the left kidney, and entering the retro-renal fatty tissue. The whole track of the bullet presented the appearance of a gangrenous hole, the gangrene in the retro-renal tissue being of the size of a fist. From this point the bullet passed into the posterior muscular tissue and could not be found, although careful search was made for four hours.

The heart was small, covered and infiltrated with fat, and the muscular walls were thinned. One dram of a turbid yellow serum was found in the pericardial cavity, but there was no evidence of injury of the heart, nor was pericarditis present. The kidneys were somewhat contracted, but all the other organs were normal.

THE CAUSE OF DEATH.

The necropsy showed that death was the result of sepsis due to gangrene resulting from the wound and that it could not have been avoided. Had the President lived twenty-four hours longer the gangrenous area around the stomach would have sloughed and death would have resulted from diffuse peritonitis.

The result of the operation so far as it went was perfect. No peritonitis was present, no particles of food were found outside of the stomach, but Nature had made no effort to repair the injury.

About twenty-four cultures were taken from the pericardium blood, right auricle, the healthy parts of the peritoneum, and along the entire gangrenous track.

REMARKS.

There has been much lay criticism because of the small bit of toast which the President was allowed to have on Wednesday morning, and these criticisms credit intestinal toxemia to its ingestion. Nothing was ordered for the President without the concurrence of all the surgeons in attendance, and the report of the autopsy just given demonstrates that the toast could have had obsolutely no effect on the outcome of the case.

Towards the last, the surgeons were inclined to believe that the wound from the first bullet on the sternum might have produced a contusion of the heart with a probable myocarditis or pericarditis from which the high pulse-rate might be due, but this hypothesis also was not borne out by the findings of the autopsy. It was at one time suggested that the President had a tobacco heart, but as he smoked only three or four cigars a day this is very unlikely.

The question whether or not the bullet was poisoned is attracting considerable attention just now. It could not have been poisoned with curare as was suggested, since this agent produces a rapid paralysis of the heart. The claim that it might have been steeped in a culture of virulent bacteria is ingenious, and Dr. Mynter says that if it had been dipped in a pure culture of pyogenic bacteria, just such a wound might have been produced. The three remaining cartridges are in the hands of Dr. Herbert Hill, the city chemist, who will make a chemical analysis, and Dr. Herman Matzinger will make a bacteriologic examination.

It has also been suggested that the necrosis might be accounted for by the injury to the pancreas and the leakage of pancreatic juice. Dr. Park considers this possible and refers to the work of Williams, Flexner and Opie in this direction.

The surgeons disclaim many reports in the lay press reported as coming from them. The official report will not be ready until next week. The bacteriologic examination of cultures taken and the microscopic examination of sections of tissues are not yet completed. The lack of leucocytosis in the blood-count may be attributed to lack of reaction in the repair of the wound. All the samples of urine taken were negative with the exception of that obtained after the operation, which, it is reported on good authority, showed hyaline casts but with a normal amount of urea and with no albumin reaction. This was considered to be possibly due to ether.

OFFICIAL BULLETINS.

BUFFALO, Sept. 6, 7 P. M.—The President was shot about 4 o'clock. One bullet struck him on the upper portion of the breastbone, glancing and not penetrating. The second bullet penetrated the abdomen five inches below the left nipple and one and one-half inches to the left of the median line. The abdomen was opened through the line of the bullet wound. It was found that the bullet had penetrated the stomach. The opening in the front wall of the stomach was carefully closed with silk stitches, after which a search was made for a hole in the back wall of the stomach. This was found and also closed in the same way. The further course of the bullet could not be discovered, although careful search was made. The abdominal wound was closed without drainage. No injury to the intestines or other abdominal organ was discovered. The patient stood the operation well. Pulse of good quality, rate of 130. Condition at the conclusion of the operation was gratifying. The result can not be foretold. His condition at present justifies hope of recovery.—George B. Cortelyou, Secretary to the President.

10:40 P. M.—The President is rallying satisfactorily and is resting comfortably. Temperature 100.4 degrees; pulse, 124; respiration, 24.—P. M. Rixey, M. B. Mann, R. E. Park, H.

Mynter, Eugene Wasdin, George B. Cortelyou, Secretary to the President.

Buffalo, Sept. 7, 1 A. M.—The President is free from pain and resting well. Temperature, 100.2; pulse, 120; respiration, 24.

3 A. M.—The President continues to rest well. Temperature, 101.6; pulse, 110; respiration, 24.—P. M. Rixey, George B. Cortelyou, Secretary to the President.

6 A. M.—The President has passed a good night; temperature, 102; pulse, 110; respiration, 24.—P. M. Rixey, Roswell Park, George B. Cortelyou, Secretary to the President.

9 A. M.—President passed a fairly comfortable night and no serious symptoms have developed. Pulse, 146; temperature, 102; respiration, 24.—P. M. Rixey, M. D. Mann, Roswell Park, Herman Mynter, Eugene Wasdin, George B. Cortelyou, Secretary to the President.

12 M.—There is no decided change in the President's condition since last bulletin. Pulse, 136; temperature, 102; respiration, 28.—P. M. Rixey. George B. Cortelyou, Secretary to the President.

3:30 P. M.—The President continues to rest quietly; no change for the worse. Pulse, 140; temperature, 102.2; respiration, 24.—P. M. Rixey, M. D. Mann, Roswell Park, H. Mynter, Eugene Wasdin, George B. Cortelyou, Secretary to the President.

6:30 P. M.—There is no change for the worse since last bulletin; pulse, 130; temperature, 102.5 degrees; respiration, 29. —P. M. Rixey, George B. Cortelyou, Secretary to the President.

9:30 P. M.—Conditions continue much the same. The President responds well to medicine. Pulse, 132; temperature, 102.5; respiration, 25. All temperatures reported are taken in the rectum. The physicians in attendance wish to say that they are too busily engaged to repy to individual telegrams.—P. M. Rixey, Roswell Park, H. Mynter, Eugene Wasdin, George B. Cortelyou, Secretary to the President.

Buffalo, September 8.—The public will be kept fully advised of the actual condition of the President. Each bulletin is carefully and conservatively prepared and is an authoritative statement of the most important features of the case at the hour it is issued. The people are entitled to the facts and shall have them.—George B. Cortelyou, Secretary to the President.

3:20 A. M.—The President has passed a fairly good night; pulse 122; temperature 102.4 degrees; respiration 24.—P. M. Rixey, H. Mynter, George B. Cortelyou, Secretary to the President.

9 A. M.—The President passed a good night and his condition this morning is quite encouraging. His mind is clear and he is resting well; wound dressed at 8:30 and found in a very satisfactory condition. There is no indication of peritonitis. Pulse 132; temperature 102.8; respiration 24.—P. M. Rixey, M. D. Mann, Roswell Park, Herman Mynter, Eugene Wasdin, George B. Cortelyou, Secretary to the President.

12 M.—The improvement in the President's condition has continued since last bulletin; pulse 128; temperature 101 degrees; respiration 27.—P. M. Rixey, George B. Cortelyou, Secretary to the President.

4. P. M.—The President since the last bulletin has slept quietly, four hours altogether since 9 o'clock. His condition is satisfactory to all the physicians present. Pulse 128; temperature 101; respiration 28.—P. M. Rixey, M. D. Mann, Roswell Park, Herman Mynter, Eugene Wasdin, Charles McBurney, George B. Cortelyou, Secretary to the President.

9. P. M.—The President is resting comfortably and there is no special change since last bulletin. Pulse 130; temperature 101.6; respiration 30.—P. M. Rixey, M. D. Mann, Roswell Park, Herman Mynter, Eugene Wasdin, Charles McBurney. George B. Cortelyou, Secretary to the President.

Buffalo, September 9, 6 A. M.—The President passed a somewhat restless night, sleeping fairly well. General condition unchanged. Pulse, 120; temperature, 101; respiration, 28.—P. M. Rixey, M. D. Mann, George B. Cortelyou, Secretary to the President.

9:20 A. M.—The President's condition is becoming more and more satisfactory. Untoward incidents are less likely to occur. Pulse, 122; temperature, 100.8 degrees; respiration, 28.—P. M. Rixey, M. D. Mann, Roswell Park, Herman Mynter, Eugene Wasdin, Charles McBurney, George B. Cortelyou, Secretary to the President.

3 P. M.—The President's condition steadily improves and he is comfortable, without pain or unfavorable symptoms. Bowel and kidney functions normally performed. Pulse, 113; temperature, 101; respiration, 26.—P. M. Rixey, M. D. Mann, Roswell Park, Herman Mynter, Eugene Wasdin, Charles McBurney, George B. Cortelyou, Secretary to the President.

9:30 P. M.—The President's condition continues favorable. Pulse, 112; temperature, 101; respiration, 27.—P. M. Rixey, M. D. Mann, Roswell Park, Herman Mynter, Eugene Wasdin, Charles McBurney, George B. Cortelyou, Secretary to the President.

Buffalo, September 10, 7 A. M.—The President has passed the most comfortable night since the attempt on his life. Pulse, 118; temperature, 100.4; respiration, 28.—P. M. Rixey, Roswell Park, George B. Cortelyou, Secretary to the President.

9 A. M.—The President's condition this morning is eminently satisfactory to his physicians. If no complications arise a rapid convalescence may be expected. Pulse, 104; temperature, 99.8; respiration, 26. This temperature is taken by mouth and should be read about one degree higher by rectum.—P. M. Rixey, M. D. Mann, Roswell Park, Herman Mynter, Eugene Wasdin, Charles McBurney, George B. Cortelyou, Secretary to the President.

3:20 P. M.—There is no change since this morning's favorable bulletin. Pulse, 110; temperature, 100; respiration, 28. —P. M. Rixey, M. D. Mann, Roswell Park, Herman Mynter, Eugene Wasdin, George B. Cortelyou, Secretary to the President.

10:30 P. M.—The condition of the President is unchanged in all important particulars. His temperature is 100.6; pulse, 114; respiration, 28. When the operation was done on Friday last it was noted that the bullet had carried with it a short distance beneath the skin a fragment of the President's coat. This foreign material was, of course, removed, but a slight irritation of the tissues was produced, the evidence of which appeared only to-night. It has been necessary on account of this slight disturbance to remove a few stitches and partially open the skin wound. This incident can not give rise to other complications, but it is communicated to the public, as the surgeons in attendance wish to make their bulletins entirely frank. In consequence of this separation of the edges of the surface wound the healing of the same will be somewhat delayed. The President is now well enough to begin to take nourishment by the mouth in the form of pure beef juice.—P. M. Rixey, M. D. Mann, Roswell Park, Herman Mynter, Charles McBurney, George B. Cortelyou, Secretary to the President.

Buffalo, September 11, 6 A. M.—The President has passed a very comfortable night. Pulse, 120; temperature, 100.2; respiration, 26.—P. M. Rixey, Eugene Wasdin, George B. Cortelyou, Secretary to the President.

9 A. M.—The President rested comfortably during the night. Decided benefit has followed the dressing of the wound made last night. His stomach tolerates the beef juice well, and it is taken with great satisfaction. His condition this morning is excellent. Pulse, 116; temperature, 100.2.—P. M. Rixey, M. D. Mann, Roswell Park, Herman Mynter, Eugene Wasdin, Charles McBurney, George B. Cortelyou, Secretary to the President.

3:30 P. M.—The President continues to gain and the wound is becoming more healthy. The nourishment taken into the stomach is being gradually increased. Pulse, 120; temperature, 100.2.—P. M. Rixey, M. D. Mann, Roswell Park, Herman Mynter, Eugene Wasdin, Charles McBurney, George B. Cortelyou, Secretary to the President.

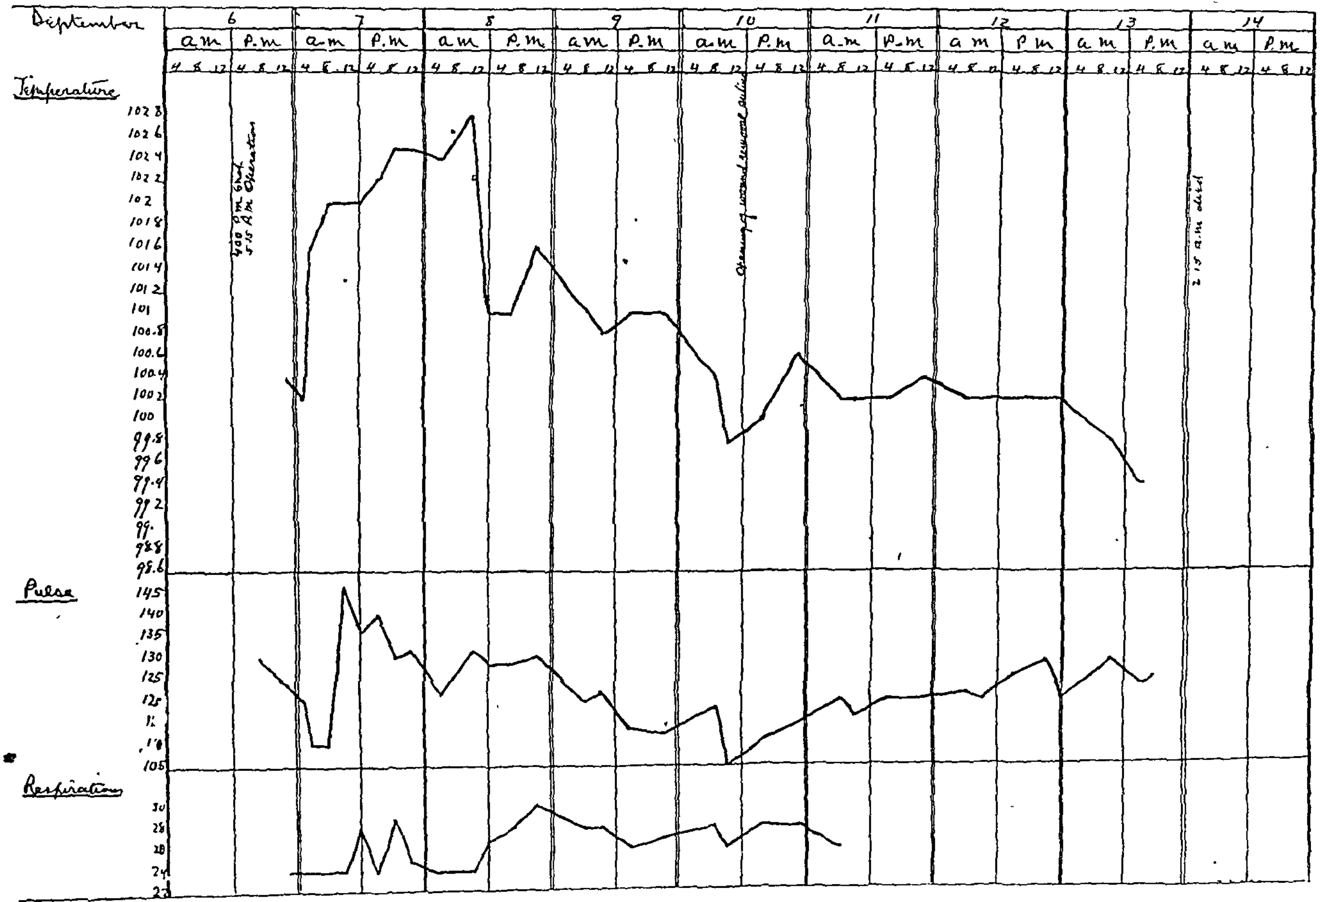
10 P. M.—The President's condition continues favorable. Blood count corroborates clinical evidence of absence of any

blood poisoning. He is able to take more nourishment and relish it. Pulse, 120; temperature, 100.4.—P. M. Rixey, M. D. Mann, Roswell Park, Herman Mynter, Eugene Wasdin, Charles McBurney, George B. Cortelyou, Secretary to the President.

Buffalo, September 12, 6:20 A. M.—The President has had a comfortable night. Pulse, 122; temperature, 100.2.—P. M. Rixey, George B. Cortelyou, Secretary to the President.

9:30 A. M.—The President has spent a quiet and restful night, and has taken much nourishment. He feels better this morning than at any time. He has taken a little solid food this morning and relished it. Pulse, 120; temperature, 100.2 degrees.—P. M. Rixey, Roswell Park, Herman Mynter, Eugene Wasdin, M. D. Mann, Charles McBurney, George B. Cortelyou, Secretary to the President.

3 P. M.—The President's condition is very much the same as this morning. His only complaint is of fatigue. He continues to take a sufficient amount of food. Pulse, 126; temperature, 100.2 degrees.—P. M. Rixey, M. D. Mann, Roswell Park, Herman Mynter, Eugene Wasdin, George B. Cortelyou, Secretary to the President.



Temperature, Pulse and Respiration Chart of the Case of President McKinley made from Official Bulletins.

8:30 P. M.—The President's condition this evening is not quite so good. His food has not agreed with him and has been stopped. Excretion has not yet been properly established. The kidneys are acting well. His pulse is not satisfactory, but has improved in the last two hours. The wound is doing well. He is resting quietly. Temperature, 100.2; pulse, 128.—P. M. Rixey, M. D. Mann, Roswell Park, Herman Mynter, Eugene Wasdin, Charles G. Stockton, George B. Cortelyou, Secretary to the President.

12 M.—All unfavorable symptoms in the President's condition have improved since the last bulletin. Pulse, 120; temperature, 100.2.—P. M. Rixey, Eugene Wasdin, Charles G. Stockton, George B. Cortelyou, Secretary to the President.

Buffalo, September 13, 2:50 A. M.—The President's condition is very serious and gives rise to the gravest apprehension. His bowels have moved well, but his heart does not respond properly to stimulation. He [illegible] ous. The skin is warm and the pulse small, regular [illegible] 126; respiration, 30; temperature, 100.—P. M. Rixey, M. D. Mann, Roswell Park, Herman Mynter, Eugene Wasdin, Charles G. Stockton, George B. Cortelyou, Secretary to the President.

9 A. M.—The President's condition has somewhat improved during the past few hours. There is a better response to stimulation. He is conscious and free from pain. Pulse, 128; temperature, 99.8.—P. M. Rixey, M. D. Mann, Roswell Park, Herman Mynter, Eugene Wasdin, Charles G. Stockton, George B. Cortelyou, Secretary to the President.

2:30 P. M.—The President has more than held his own since morning, and his condition justifies the expectation of further improvement. He is better than yesterday at this time. Pulse, 123; temperature, 99.4.—P. M. Rixey, M. D. Mann, Herman Mynter, Eugene Wasdin, Charles G. Stockton, George B. Cortelyou, Secretary to the President.

4 P. M.—The President's physicians report that he is only slightly improved since the last bulletin. The pulse and temperature remain the same as at that hour.—George B. Cortelyou, Secretary to the President.

5:35 P. M.—The President's physicians report that his condition is grave at this hour. He is suffering from extreme prostration. Oxygen is being given. He responds to stimulants but poorly. Pulse, 125; respiration, 40.—George B. Cortelyou, Secretary to the President.

6:30 P.M.—The President's physicians report that his condition is most serious in spite of vigorous stimulation. The depression continues and is profound. Unless it can be relieved the end is only a question of time.—George B. Cortelyou, Secretary to the President.

9:30 P. M.—"The President is dying."

Buffalo, September 14, 2:15 A. M.—"The President is dead."

Buffalo, September 14.—Autopsy.—The bullet which struck over the breastbone did not pass through the skin and did little harm. The other bullet passed through both walls of the stomach near its lower border. Both holes were found to be perfectly closed by the stitches, but the tissue around each hole had become gangrenous. After passing through the stomach the bullet passed into the back walls of the abdomen, hitting and tearing the upper end of the kidney. This portion of the bullet track was also gangrenous, the gangrene involving the pancreas. The bullet has not yet been found. There was no sign of peritonitis or disease of other organs. The heart walls were very thin. There was no evidence of any attempt at repair on the part of nature, and death resulted from the gangrene which affected the stomach around the bullet wounds as well as the tissues around the further course of the bullet. Death was unavoidable by any surgical or medical treatment, and was the direct result of the bullet wound.—Harvey D. Gaylord, M.D.; Herman G. Matzinger, M.D.; P. M. Rixey, M.D.; Matthew D. Mann, M.D.; Herman Mynter, M.D.; Charles Cary, M.D.; Edward L. Munson, Assistant Surgeon United States Army; Roswell Park, M.D.; Eugene Wasdin, M.D.; Charles G. Stockton, M.D.; Edward G. Janeway, M.D.; W. W. Johnston, M.D.; W. P. Kendall, Surgeon United States Army; Hermanus L. Baer, M.D.

Medical News.

[Because of the large amount of Educational matter, and likewise of that on the death of the President, a considerable portion of our regular Departments has been crowded out.]

ILLINOIS.

Dr. Andrew H. Kimbrough, Danville, is seriously ill as the result of a paralytic stroke.

The new hospital at Elgin, which was to have been opened September 1, by the Sisters of St. Joseph, is not yet ready, and the opening has been postponed indefinitely.

Smallpox is reported from East Hillsboro, and from Champaign County near Tolono. In the first case the infection is supposed to have been received at Alton, and in the second at Peoria.

Chenoa Doctors Raise Rates.—At a meeting of the physicians of Chenoa it was decided that to be in harmony with the physicians of McLean and Livingston counties all fees charged would be the same as agreed upon by the medical societies of the two counties.

Personal.—Dr. Babcock Meloy has succeeded to the practice of the late Dr. Katharine Miller, Lincoln.——Dr. William C. Dixon, Terre Haute, has moved to Canton.——Dr. Emerson M. Sutton, Peoria, has returned from Europe.——Dr. Isaac B. Ennis, Martinton, has located in Gilman.——Dr. J. Frank Wilson, Versailles, has moved to Bluffs.——Dr. Edmund Ludlow, Paxton, has gone to Denver, Colo., to practice.——Dr. Edward D. Howland, Lockport, has moved to Chicago.——Dr. William K. Farley, Waterman, has gone to Oregon.——Dr. and Mrs. William D. Nelson, Jr., Marietta, have gone to Europe for study.——Dr. Edward C. Lemen, Jr., Upper Alton, has been commissioned assistant surgeon of Volunteers, with the rank of captain, and assigned to the Eighth Infantry, U. S. army.

Chicago.

The Chicago Eye, Ear, Nose and Throat Hospital has provided a number of free beds for charity patients.

To Sterilize Pencils.—Dr. Arthur R. Reynolds, commissioner of health, has recommended the sterilization of pencils used in the public schools.

Baptist Hospital Changes.—Dr. Reuben Peterson has resigned as gynecologist, and Dr. Palmer Findley has been appointed in his stead.——Dr. A. E. Halstead has been appointed to the surgical staff and Dr. Charles E. Paddock obstetrician.

Scarlet Fever in Rogers Park.—There are now 55 cases of scarlet fever in this suburb with two deaths, and the Health Department has been forced to threaten to station policemen at the doors of infected houses unless the quarantine is more strictly observed.

New Hospital.—The new hospital of the Sisters of Mary, erected at a cost of $250,000, is nearing completion. The structure is six stories high, fire-proof, of cut stone and pressed brick, with strikingly high porticoed entrances. The ground dimensions are 196 by 87 feet. The operating rooms are on the top floor. On the north and south sides of the building are inclosed porches, which can be so heated as to be habitable the year around.

Personal.—Dr. Robert A. McArthur has returned from his summer vacation.——Dr. James Nevins Hyde has returned from his summer vacation in Salem.——Dr. and Mrs. Julian E. Hequembourq have returned from a month's visit to the Massachusetts coast.——Dr. Emma Morgan has located in Rock Island.——Dr. Paul E. N. Greeley has moved to Waterman.——Dr. James M. Lyons has opened an office in Lockport.——Dr. H. R. Struthers has located in Martinton.

Banquet to Dr. N. S. Davis, Sr.—The Chicago Medical Society is arranging to tender a banquet to Dr. N. S. Davis, at the Auditorium Hotel, Chicago, Saturday evening, October 5. Dr. Davis is the oldest living ex-president of the Society, one of the founders and the oldest living ex-president of the American Medical Association, widely known and highly respected by the profession of the whole country, and a man who has always stood out for the best interests of the American medical profession. He deserves all the honors that any society can confer on him.

Anthrax.—The recent outbreak of anthrax at Palatine, and its increasing prevalence in the surrounding country, which is largely devoted to dairying interests, prompted the health commissioner to send the secretary of the department, together with one of its meat inspectors—an expert veterinarian—to that section to investigate the existing conditions. As a result, and at the suggestion of the representatives of the department, the farmers throughout the infected district have formed a local association for the purpose of stamping out the disease and preventing its further spread. This association, through its officers, has pledged the department that no milk or veal calves or beef cattle will be shipped from any of the infected herds. In view of these pledges, and the thoroughly reliable character of the men who made them, it was not deemed necessary on the part of the city to establish any quarantine against the food supplies from this district. It is believed that with the enforcement of the measures now under way the present outbreak will soon be under control.

The Smallpox Situation.—The Health Department points out that in the group of states of which Illinois is the center and with which Chicago is in most immediate and constant communication, there have been, during the first 36 weeks of this year, a total of 15,373 cases of smallpox reported, as against a total of only 5620 cases reported during the corresponding period of 1900. This is an increase of 273 per cent. in Northwestern states as against an increase of less than 75 per cent. in the rest of the country. In the state at large, outside of Chicago, there have been fewer cases—229—this year than last—250—but in the city itself there have been 248 cases this year, as against only 51 last year. This great increase—nearly five times more than last year—is due, of course, to the repeated importations from the surrounding infected territory, and while no new case has been discovered since August 12, and the city has been free from the disease since August 28, it is not to be expected that further importations can be prevented during the fall and winter. The experience in New York City forbids such hope; there they have had this year, up to the close of August, 1831 cases and 370 deaths—as against Chicago's 248 cases and 2 deaths. The lesson of these facts and figures is that Chicago is more exposed now than a year ago, and that individuals not properly protected by vaccination are in greater danger of contracting smallpox now than then.

INDIANA.

Typhoid fever in Muncie is reported to be much more fatal than usual and, it is said, is not water but mosquito borne.

Dr. Brose S. Horne, Bluffton, has been appointed physician of the state penitentiary at Michigan City, vice Dr. Alva L. Spinning, resigned.

A Methodist hospital and deaconess' home to cost not less than $200,000 is to be built in Indianapolis on land recently purchased at 29th and Illinois streets.

Dr. Baker's Death.—The faculty of the Medical College of Indiana has passed resolutions expressing the loss sustained by the college in the death of Dr. Philip S. Baker, who for many years had held the chair of chemistry.

Personal.—Dr. Samuel M. Reid has resigned as city health officer of Muncie.—Dr. Brook B. Freeman, Valparaiso, is critically ill with dropsy.—Dr. Frank Songer, Hillsboro, who has been ill for five months, will spend the winter in Florida.—Dr.

Frank H. Wilcox, New Albany, has been elected township physician.

KANSAS.

Smallpox.—The Secretary of the State Board of Health reports that at the end of August there were less than a dozen cases of smallpox in the state, in five localities. On September 2 two new cases of the disease were discovered in Topeka.

Personal.—Dr. B. W. Toothaker will remove from Westmoreland to St. Joseph, Mo.—Dr. Edward Trachsell, Meriden, has moved to Denver, Colo.—Dr. Carroll Montgomery has decided to remain in Manhattan, and assume charge of the practice left by his father.

New Medical Law.—The registration of physicians prior to the date the new medical law went into effect amounted to 2300 of the 2600 physicians estimated to be in the state. Of these about 1600 presented diplomas from reputable medical colleges; 100 had certificates from other states; 400 were admitted under the seven-year practice clause and the remainder took the prescribed examination.

MICHIGAN.

A "Christopathic" sanatorium is the latest addition to the roll of sanatoria in Battle Creek.

Personal.—Dr. D. E. Newcomb, Carleton, was stricken with paralysis September 6, and is in a precarious condition.—Dr. Abiel S. Martin, Vicksburg, intends to locate in Otsego. —Dr. P. H. Wilson, Hancock, has been appointed physician to Baltic mine.

Transportation of Bodies.—At a special meeting of the State Board of Health a rule was adopted providing that all bodies, without regard to cause of death, will be subject to transportation, when prepared by licensed embalmers in accordance with the rules of the State Board. In all states with the exception of Michigan, the transportation of bodies dead from smallpox, Asiatic cholera, yellow fever, typhus fever or bubonic plague, is absolutely forbidden. By permitting the transportation of such bodies in Michigan, the qualifications of licensed embalmers are recognized. The detailed rules in caring for such bodies will insure the public health against contagion from these bodies.

NEW YORK.

Personal.—Dr. Homer E. Smith, Norwich, has returned from his trip to South America.—Dr. Homer C. Tarbell, West Groton, has opened an office in Groton.—Dr. James King, Buffalo, who has been in Vienna for the past five months, is now in London, England.

State Antitoxin Laboratory.—A building has been secured for the establishment of a state antitoxin laboratory in Albany and Dr. H. D. Pease, of the Sheffield Scientific School, Yale University, has been appointed director. The animal house will be provided with the most perfect hygienic conditions attainable for such purposes, and will be supplied with about 15 horses for the manufacture of serum. The Commissioner of Health proposes to supply state institutions with diphtheria and other antitoxins free of cost, and also to furnish these remedies to municipalities in the state which are not already provided with a similar laboratory. These new departments are intended to supply to all the health officers throughout the state the same facilities for investigation, diagnosis and treatment of infectious diseases now afforded by the city of New York.

Mortality of New York.—According to the state health department's report for July, New York City reported 1155 deaths from insolation and in the entire state 1283 deaths were ascribed to the effects of heat. There were 8 deaths reported from lightning stroke, and 111 deaths occurred from drowning, altogether making over 2000 deaths attributed to accidents and violence, much beyond any former record. The rural death rate was 13 per 1000 population, the urban being 23, while that of the entire state was about 20. There were 400 deaths from pneumonia out of 602 from all acute respiratory diseases, and of 400 deaths from diseases of the urinary system, outside of New York City, 240 were from Bright's disease. Smallpox is reported as causing 89 deaths, a number in excess of that of any heretofore recorded, 74 having occurred in June; of these, 80 occurred in New York City, where about 250 new cases developed during July, the last four weeks showing a decrease.

Buffalo.

Census Statistics.—In New York City there are 638,045 foreign born males and 632,035 foreign-born females. In the entire city there are 33,587 colored males, of which 27,132 are negroes, and 33,717 females, of whom 33,534 are negroes. The same locality presents in return native males 1,067,660, and native females 1,099,462. The exact enumeration in the case of the four boroughs of New York City is given without materially disturbing the ratio of the percentages, barring the colored element.

OHIO.

Medical Colleges Open.—Ohio Medical University, Columbus, opened September 11, with 197 new students registered and more than 400 present at the opening exercises.—Starling Medical College opened the same day with an initial registration exceeding one hundred.

Personal.—Dr. Kate M. Johnson has opened an office in Wooster.—Dr. E. B. Davis has located in Covington.—Dr. Johnson S. Hunter, Piketon, has moved to Jackson.—Dr. Luther Schofield has moved from White House to Maumee.—Dr. David H. Biddle has moved from Haydenville to Athens.—Dr. O. S. Wood, Pomeroy, has located in Haydenville.

Grand Army Medical Arrangements.—The medical committee for Grand Army week at Cleveland was made up of two corps of physicians; the first a consultant body and the second an active medical corps of relief. Dr. George C. Ashmun was chairman of the committee. The consulting body was composed of 24 physicians, some of whom were constantly on duty at headquarters. The medical corps of relief was made up of 32 physicians who answered telephone calls from all parts of the city. The committee provided 19 ambulances, which were stationed at intervals along the line of march.

PENNSYLVANIA.

Typhoid fever is reported to be epidemic at Bolivar.

Anthrax is raging among cattle on Loyalsock Creek, and two persons at Laporte have been infected.

A physician of Bismarck has been arrested by order of the president of the Cornwall Township school board, charged with having neglected to report a case of smallpox.

Personal.—Dr. James Mitchell has returned from his service with the army in the Philippines and will open an office in Lancaster.—Dr. W. S. Bertelot has located for practice in Reading.

A patent medicine vender of Washington, D. C., who was tried at Chambersburg for practicing and prescribing medicine without a license, was acquitted on the technicality that she had not opened an office.

Dr. Miller Honored.—Philadelphia professional friends of Dr. John S. Miller, Denver, Col., who was formerly one of the demonstrators of anatomy in the Jefferson Medical College and surgeon to St. Joseph's Hospital, Philadelphia, tendered him a dinner, September 10. Professor Francis X. Dercum, of Jefferson Medical College, presided and acted as toastmaster.

Medico-Chirurgical Hospital Improvements.—At a cost of $70,000 extensive improvements have been begun to the Medico-Chirurgical Hospital, Philadelphia, which will be completed in October. The infirmary will be moved into the new building at Seventeenth and Cherry streets, which is now practically finished. The old dental laboratories will also be moved from the rear of the hospital into the new building, and will be made into a dormitory for nurses. The old laundry adjoining the accident room will be discontinued, and this, together with the present dispensary, will be made into a new receiving ward for the treatment of emergency cases. Two new refrigerating plants are to be installed.

MARYLAND.

Dr. J. Walter Sims, Cooksville, has been indicted for not reporting to the State Board of Health the existence of smallpox in his neighborhood.

Typhoid fever is epidemic in Cumberland County. The local board of health attributes the spread of the disease to flies and has informed residents that they must make war on the flies, which, it believes, carries the disease from house to house.

Personal.—Dr. Albert K. Hadel, Baltimore, is at Cape May.——Dr. William Oakley Haines, Baltimore, has gone to Canada.——Dr. Thomas Sudler, Baltimore, former city councilman, has been presented with a handsome silver service.——Dr. Sewell S. Hepburn, Jr., West River, has moved to Annapolis.

Nurses for the Insane.—The recommendation of Dr. J. Clement Clark, superintendent, that a training school for nurses be established at Springfield State Hospital for the Insane, was adopted at the last meeting of the Board of Directors. There are 20 male and 16 female nurses who will be instructed on the treatment and care of the insane by the medical staff and supervisors. The course will be a two years' one, and a certificate and increase of salary is to be given to the graduates. There were in the hospital, August 31, 328 patients, 231 male and 97 female.

Site for Isolation Hospital.—Health Commissioner Bosley has been authorized to secure an option on ten acres of land on the Reisterstown road near Pimlico and West Arlington, as the site for the Municipal Hospital for infectious diseases. Dr. Bosley's idea is to erect several different buildings on the property, thus keeping the patients suffering from one infectious disease separated as much as possible from those with others. To do this it is estimated the commission will need considerable more money than the $25,000 which has been provided, and an additional appropriation will be included for this purpose in the ordinance of estimates for the year 1902.

CANADA.

Physician Arrested.—A Toronto doctor was arrested on the 13th, charged with procuring an abortion.

Huron Medical Association.—The regular quarterly meeting of this Association was held at Clinton, Ontario, on September 6. Dr. William Graham, presided, and Dr. J. W. Shaw acted as secretary.

College of Physicians and Surgeons, Quebec.—Sixteen physicians will represent the District of Montreal on this Board for the ensuing year, thirteen the District of Quebec, three the District of Three Rivers, and three the District of St. Francis.

Personal.—Dr. Laberge, medical health officer of Montreal, has started for Germany.——Dr. W. H. P. Hill, who has just completed his term as house surgeon at the Montreal General Hospital, has gone to Europe prior to entering upon practice in Montreal.

Montreal General Hospital.—The medical staff of the Montreal General Hospital for the ensuing year will be made up as follows: Dr. von Eberts, medical superintendent, and Drs. Turner, Secord, Robertson, Campbell, Howard, Bruce, Brown, Rogers and Ker as house surgeons.

Dr. Montizambert, director of public health, has handed in his report to the Minister of Agriculture on the recent Tuberculosis Convention at London. It is understood that the report combats Professor Koch's theory that bovine tuberculosis is not transmissible to human beings.

Dowieites Arrested.—A special dispatch from Victoria, B. C., dated the 12th inst., states that an elder of the Dowieite persuasion and one of his disciples have been arrested on a charge of manslaughter for refusing to provide proper medical assistance for the infant child of the latter.

Bacteria in Cheese.—On account of frequent complaints as to certain cheese being "off" flavor, Professor Harrison, bacteriologist of the Ontario Agricultural College, was ordered by the government to investigate, and he has found a species of bacteria which he thinks is responsible for the trouble.

Toronto Druggists to Meet.—There is to be held on the 19th inst., a general meeting of the retail druggists of Toronto for the purpose of considering relations with the proprietary trade. It is understood that a number of the druggists of the city are in favor of cutting adrift from patent medicines.

Collapsed in the Witness Box.—Two years ago Dr. J. H. Morrison, an oculist of St. John, N. B., was injured in a street railway accident in that city. He sued the company for $60,000, and after various delays the suit came up for trial during the past week. While under examination the doctor collapsed from nervous strain and is now said to be at the point of death. Dr. Morrison was for many years inspector of schools in Manitoba.

Doctor Appeals to the Courts.—Dr. H. C. Dumont, who has been denied a license to practice in the Province of Quebec, has been granted a petition for a writ of mandamus by Mr. Justice Langelier against the College of Physicians and Surgeons of that province. The writ of mandamus orders the College to issue the license. Five or six cases of a similar nature were decided in Quebec last year in a similar manner. The College will take the case through the Court of Appeal, and, if necessary, to higher courts.

St. Francis Medical Association.—This Association held its regular meeting on Thursday, the 13th inst. Dr. McCabe, of Windsor Mills, was recommended to the position of joint coroner of the district in succession to the late Dr. McMorrine. Dr. P. Pelletier reported that it was the intention of the Quebec Provincial Board of Health to take steps to instruct the people in hygiene, and that a convention would be held shortly at Sherbrooke in this connection. He asked the support of the Association for this movement. The following officers were elected for the ensuing year: President, Dr. J F. Rioux, Sherbrooke; first vice-president, Dr. W. D. Smith, Sherbrooke; second vice-president, Dr. McCabe, Windsor Mills; honorary secretary, Dr. Russell Thomas, Lennoxville.

War on the Ontario Medical Council.—A meeting of the executive committee of the Medical Defense Association, which it will be understood has nothing to do with defending practitioners from suits for alleged malpractice, and is no part nor parcel of the organization recently perfected at the Canadian Medical Association meeting—the Physicians' Protective Association—was held recently in Toronto, when a sub-committee of publication was appointed to supervise the issuing of a short series of letters to the public press setting before the profession, the public and the legislature of the province the disabilities under which the medical profession in Ontario is supposed by the members of this Association to be resting. Dr. J. H. Sangster, of Port Perry, has undertaken to do this work at the urgent and unanimous wish of his executive committee: and for the next month or two the officials of the Medical Council will be kept busy reading what Dr. Sangster thinks of that august body.

British Columbia Medical Association.—The second annual meeting of this Association was held at Victoria on the 5th and 6th inst. and there was a good representation of the profession from the province. Several eastern physicians came on from the meeting of the Canadian Medical Association at Winnipeg. On the forenoon of the first day the delegates were taken by special steamer to the William Head quarantine station, which was inspected. In the afternoon, Dr. John Dunc, the president, delivered the annual presidential address [illegible]ory of medicine from his student days. D[illegible], of Nanaimo, read a paper on midwifery, which provoked an interesting discussion. On the afternoon of the 6th the visitors were taken to D'Arcy Island, where the lepers were inspected. In the forenoon, Dr. Fagan read a paper on tuberculosis, and in the evening a banquet was held at the Driad. The following officers were elected for the ensuing year: President, Dr. Walker, New Westminster; vice-president, Dr. Helmcken; secretary, Dr. Pearson, Vancouver.

Deaths and Obituaries.

John Eliot Woodbridge, M.D., Charity Hospital Medical College, Cleveland, Ohio, 1866, a member and former trustee of the American Medical Association, died at Bad Nauheim, Germany, from heart disease, August 31, aged about 55. After graduation he practiced for a time in Kentucky and as an acting assistant surgeon in the army. In 1870 he settled in Youngstown, Ohio, where he speedily gained a large practice. It was in 1884 that he first began to experiment with the treatment for typhoid fever, which has since been known by his name, and for a time attained a measure of popularity with the profession. At the outbreak of the Spanish-American war he entered the Volunteer army as major and surgeon and was placed in charge of the hospital at Fort Meyer. A year ago, to regain his health he went abroad, spent the winter in Egypt and then went to Bad Nauheim, where he died.

Gustav Schiff, M.D., University of Würzburg, Germany, 1856, who had practiced in Chicago, Nashville, Dallas and San Francisco; served throughout the Civil war, and labored heroically during the Tennessee cholera epidemics of 1866 and 1873, died at his home in San Francisco, September 2, from Bright's disease, aged 68.

John M. Meyer, M.D., Transylvania University, Lexington, Ky., 1843, the oldest practicing physician in Kentucky, and a member of the American Medical Association, who had been in declining health for some time, died at his home in Danville, September 5, aged 84.

Philip Schaffner Baker, M.D., Medical College of Indiana, Indianapolis, 1879, professor of chemistry in De Pauw University, Greencastle, Ind., and known throughout the country as an educator, died at Asheville, N. C., September 2, from tuberculosis, aged 50.

Conrad R. Ohlinger, M.D., Ohio Wesleyan University, Cleveland, 1898, of Cleveland, acting assistant surgeon, U. S. Army, was drowned while returning from a scouting expedition in the Pambugan Mountains, Samar, Philippine Islands, August 20.

Sidney Rogers Burnap, M.D., College of Physicians and Surgeons, New York, 1862, a prominent physician of Windsor Locks, Conn., died at his home in that place, September 3, from brain tumor, after an illness of several months, aged 68.

Edmund P. Duval, M.D., University of Pennsylvania, Philadelphia, 1847, a practitioner for 33 years in Maryland, and from 1880 to 1892 state librarian of Maryland, died at his home in Annapolis, September 5, aged 75.

Alonzo D. McComb, M.D., Western Reserve University, Cleveland, Ohio, 1880, for twenty years a practitioner of medicine in Hawthorne, Pa., died at his home in that place, September 5, from Bright's disease, aged 47.

Etienne Gosselin, M.D., Laval University, Quebec, 1883, a prominent physician of Quebec, died at his home in that city, September 6, from typhoid fever, after an illness of three weeks, aged 46.

Louis Warfield Ritchie, M.D., University of Georgetown, Washington, D. C., 1863, a veteran of the Civil war, died at his home in Washington, September 9, from Bright's disease, aged 58.

Charles F. Atwood, M.D., Bellevue Hospital Medical College, New York, 1879, died at his residence in Winterport, Maine, September 6, after an illness of two weeks, aged 45.

William Washington Rigby, M.D., Baltimore Medical College, 1892, died at his home in Spartanburg, S. C., from typhoid fever, after a long illness, September 4, aged 30.

Charles De Saussure Clarkson, M.D., Medical College of the State of South Carolina, 1890, died suddenly from apoplexy, at his home in Allendale, S. C., September 3, aged 35.

George Lewis Staley, Jr., M.D., College of Physicians and Surgeons, Baltimore, 1878, died at his home in Baltimore, September 9, after an illness of six weeks, aged 44.

Dennis B. Dorsey, M.D., College of Physicians and Surgeons, Keokuk, Iowa, 1891, died at his home in Braymer, Mo., September 2, after a prolonged illness, aged 71.

John R. Williams, M.D., Vanderbilt University, Nashville, Tenn., 1892, died at his home in Port Royal, Tenn., from typhoid fever, September 3, aged 33.

Samuel R. Owens, M.D., University of Tennessee, Nashville, 1886, died at his home near Somerset, Ky., August 29, aged 76.

Charles W. Adkins, M.D., University of Louisville, Ky., 1858, died at his home in Langston, Ala., September 4, aged 60.

J. M. Winn, M.D., died at his home in Forest City, Ill., September 5, aged 71.

Book Notices.

A Practical Treatise on Medical Diagnosis for Students and Physicians. By John H. Musser, M.D., Professor of Clinical Medicine in the University of Pennsylvania. Fourth Edition, Revised and Enlarged. Illustrated with 250 Woodcuts and 49 Colored Plates. Cloth. Pp. 1105. Price, $6.00. Philadelphia and New York: Lea Brothers & Co. 1900.

This excellent volume is well supplied with artistic and, for the most part, original illustrations, and the text is clear and concise. In this edition the author has introduced the latest acquisitions of medical research. His desire to make use, as much as possible, of methods of scientific precision, has placed the work facile princeps of its class. The treatise should find its way into the library of every practitioner and student, if it is not there already.

The Treatment of Fractures. By Charles Locke Scudder, M.D., Surgeon to the Massachusetts General Hospital, Out-Patient Department. Assisted by Frederick J. Cotton, M.D. Second Edition, Revised. With 611 Illustrations. Cloth. Pp. 457. Price, $4.50 net. Philadelphia and London: W. B. Saunders & Co. 1901.

That a second edition of this work should be necessary in less than a year speaks well for the manner in which the first edition was received by the profession. As the first edition was so recently reviewed in these columns, it will be necessary to mention here only the changes and additions which appear in this, the second edition. One of the most important changes is the introduction of a number of additional *x*-ray plates. The value of the *x*-ray plate in the diagnosis of many fractures can not be overestimated. The value, therefore, of the introduction of good *x*-ray plates of the various fractures in a work of this kind is very apparent. A series of clinical cases has also been introduced, which makes a fitting supplement to the chapter on skull fractures. The use of plaster-of-paris dressings in the treatment of fractures is particularly emphasized, and numerous excellent plates have been introduced illustrating the various methods of their application. The same excellent style has been maintained in the work, and the publisher's part equally well done.

Association News.

New Members.

The following is a list of new members of the American Medical Association for the month of August:

ALABAMA.
Westmoreland, H. D., Huntsville.

ARKANSAS.
MacCammon, Vernon, Arkansas City.
Graham, J. F., Hot Springs.

CALIFORNIA.
Cagliera, G. E., San Francisco.

CONNECTICUT.
Lynch, Robt. J., Bridgeport.

FLORIDA.
Bize, L. A., Tampa.

ILLINOIS.
Kilbourne, E. D., Chicago.
Sharpe, Anne McFarland, Jacksonville.
Stees, Marie J., Freeport.
Chapin, C. E., Bloomington.
Lucas, F. B., Peoria.
Hopkins. S. W., Walnut.
Heywood, C. W., Riverside.
Becker, E. C., Chicago.
Swan, C. F., Chicago.
Burdick. A. B., Chicago.
Melton, W. A., Jr., Warrensburg.

IOWA.
Beach, M. A., Carroll.
Stiles, F. N., Davenport.
Hoxie, W. E., Hampton.
Pollock, W. L., Boone.
Stalford, G. A., Latimer.
Russell, C. R., Ottumwa.
Smith, E. J., Harlan.
Cantwell, J. D., Davenport.

INDIANA.
Wolferman, A. Gertrude, Indianapolis.
Keller, F. G., Alexandria.

KANSAS.
Wever, J. S., Leavenworth.
Berry, J. A., Topeka.

KENTUCKY.
Wash, Bishop, Cornishville.
Bates, S. W., Sheperdsville.
Rodgers, J. F., Bowling Green.
Cain, C. E., Mt. Victory.

LOUISIANA.
McBride, R. E., Houma.
Ballowe, H. L., Diamond.

Mason, C. H., West Superior.
Coon, J. W., Milwaukee.
Minshall, A. P., Viroqua.

Miscellany.

Medical Corps of the U. S. Army. Information for Candidates Seeking Appointment.

The Medical Corps of the Army, as increased from a total of 192 to 321 medical officers by recent Congressional action, consists of a Surgeon General with the rank of brigadier general, eight Assistant Surgeons General with the rank of colonel, twelve Deputy Surgeons General with the rank of lieutenant colonel, sixty Surgeons with the rank of major, and two hundred and forty Assistant Surgeons with the rank of first lieutenant, mounted, for the first five years, and the rank of captain, mounted, thereafter, until promoted to major. Section 1172, Revised Statutes of the United States, provides that "No person shall receive the appointment of Assistant Surgeon unless he shall have been examined and approved by an Army Medical Board, consisting of three Surgeons or Assistant Surgeons, designated by the Secretary of War; and no person shall receive the appointment of Surgeon unless he shall have served at least five years as an Assistant Surgeon in the Regular Army, and shall have been examined and approved by an Army Medical Board, consisting of not less than three Surgeons, designated as aforesaid." The act to increase the efficiency of the military establishment of the United States, recently approved, further provides "That the period during which any Assistant Surgeon shall have served as a Surgeon or Assistant Surgeon in the Volunteer Army during the war with Spain or since shall be counted as a portion of the five years' service required to entitle him to the rank of captain. All vacancies are filled by appointment to the junior grade (first lieutenant). Promotion through the intermediate grades of rank from that of captain to that of colonel is by seniority, but there is an examination for the rank of captain and another for that of major, to ascertain the fitness of the officer for promotion. Advancement to lieutenant colonel and colonel takes place without further examination. The Surgeon General is selected by the President from among the members of the corps.

Pay and Emoluments.—To each rank is attached a fixed annual salary, which is received in monthly payments, and this is increased by 10 per cent. for each period of five years' service until a maximum of 40 per cent. is reached. An Assistant Surgeon with the rank of first lieutenant, mounted, receives $1600 per annum, or $133.33 monthly. At the end of five years he is promoted to captain and receives $2000 a year, which, with the increase of 10 per cent. for five years' service, is $2200, or $183.33 per month. After ten years' service as captain the pay would be $2400 annually, or $200 per month. The pay attached to the rank of major is $2500 a year, which, with 10 per cent. added for each five years' service, becomes $3000 after 10 years' service, $3250 after fifteen years and $3500 after twenty years. The monthly pay of lieutenant colonel, colonel, and brigadier general is $333.33, $375, and $458.33 respectively. Officers in addition to their pay proper are furnished with a liberal allowance of quarters according to rank, either in kind, or, where no suitable Government building is available, by commutation. When traveling on duty an officer receives mileage for the distance traveled; the amount allowed is sufficient to cover all expenses of journey. On change of station he is entitled to transportation for professional books and papers and a reasonable amount of baggage at Government expense. Mounted officers, including all officers of the Medical Corps, are provided with forage, stabling, and transportation for horses owned and actually kept by them, not exceeding two for all ranks below a brigadier. Groceries and other articles may be purchased from the Commissary and fuel from the Quartermaster's Department at about wholesale cost price. Instruments and appliances are supplied in abundance for the use of medical officers in the performance of their duties. Well selected professional libraries are supplied to each hospital and standard modern publications on medical and surgical subjects are added from time to time; current issues of a number of representative medical journals are also furnished for use of medical officers.

Army Medical School.—In 1893 the Secretary of War authorized the establishment of an Army Medical School in the city of Washington for the purpose of instructing medical officers who have been appointed since the last preceding term of the school, and such others as may be authorized to attend.

The course of instruction is for five months, and will be given annually, when practicable, at the Army Medical Museum, in Washington City, commencing in November. Five professors are selected from among the senior medical officers of the Army, stationed in or near the city of Washington, also an instructor in first aid and ambulance drill. . . .

Duties and Privileges.—Leave of absence on full pay is allowed at the rate of one month per year, and this when not taken may accumulate to a maximum of four months, which at the end of four years is then available as one continuous leave. Beyond this an officer may still be absent with permission on half pay. Absence from duty on account of sickness involves no loss of pay.

Medical officers are entitled to the privilege of retirement at any time for disability incurred in the line of duty, or after forty years' service. On attaining the age of sixty-four they are placed upon the retired list by virtue of law. Retired officers receive three-fourths the amount of their pay proper at the time of retirement.

When medical officers with the rank of captain approach the period of their examination for promotion to a majority they are usually assigned to duty as attending surgeons in the principal medical centers of the United States, to enable them to become familiar with the practice of the leading physicians and surgeons in this country, and to attend medical lectures, meetings of medical societies, etc. These assignments are made for one year only, in order that as many medical officers as possible may be enabled to avail themselves of the advantages thereby afforded. At the end of this tour of duty they are required to make a detailed report to the Surgeon General showing how much of their time has been occupied by their official duties and to what extent they have availed themselves of the advantages offered for professional advancement. . . .

Examination.—Permission to appear before the Board is obtained by letter to the Secretary of War, which must be in the handwriting of the applicant, giving the date and place of his birth and the place and State of which he is a permanent resident, and inclosing certificates, based on personal acquaintance, from at least two reputable persons as to his citizenship, character, and habits. The candidate must be a citizen of the United States, between twenty-two and twenty-nine years of age, in the case of a candidate applying for appointment from civil life, and between twenty-two and thirty-four years of age in the case of a candidate who has served honorably in the Army of the United States, either as a commissioned medical officer of volunteers or as an Acting Assistant Surgeon during the war with Spain or since. He must be of sound health and good character, and a graduate of some regular medical college, in evidence of which his diploma will be submitted to the Board. The scope of the examination includes the morals, habits, physical and mental qualifications of a candidate, and his general aptitude for service; and the Board will report unfavorably should it have a reasonable doubt of his efficiency in any of these particulars. The physical examination comes first in order, and must be thorough. Candidates who fall below sixty-four inches in height will be rejected. Each candidate is also required to certify "that he labors under no mental or physical infirmity or disability which can interfere with the efficient discharge of any duty which may be required." Errors of refraction, when not excessive, and not accompanied by ocular disease, and when correctible by appropriate glasses, are not causes for rejection. The professional examinations are conducted by both written and oral questions, upon anatomy, physiology, chemistry, hygiene, pathology and bacteriology, therapeutics and materia medica, surgery, practice of medicine, obstetrics and the diseases of women and children. Examinations are also conducted at the bedside in clinical medicine and surgery, and operations and demonstrations are required to be made by the candidate upon the cadaver. Hospital training and practical experience in the practice of medicine, surgery, and obstetrics are essential to candidates seeking admission to the Medical Corps of the Army, who will be expected to present evidence that they have had at least one year's hospital experience, or the equivalent of this in practice. Candidates presenting a degree in arts, sciences (other than medicine) or literature, those who hold first-class teachers' certificates or who submit evidence of graduation from a reputable high school or similar institution (approved by the Board), will not usually be examined in other than the professional subjects enumerated above. Should a candidate, during his professional examination by the Board, present evidence of a deficiency in his general education in elementary subjects, he may be required to undergo an oral examination in arithmetic, history, geography, literature, and physics, and such examination, if unsatisfactory, will be cause for his rejection. Candidates claiming especial knowledge of the higher mathematics, ancient or modern languages, drawing, analytical chemistry, or branches of natural science, will be examined in those subjects as accomplishments and will receive due credit therefor according to their proficiency. To save unnecessary expense to a candidate desiring a preliminary physical examination, written authority may be given by this office for him to present himself at the nearest military post, garrison, or recruiting station for such examination. Any opinion given as to the result of such preliminary examination must, however, be considered as purely advisory and not as determining the subsequent action of an Army Medical Board in the case.—Circular of the Medical Department.

Intellectual Precocity Among Physicians.—The *Semaine Médicale*, in a recent review of this subject, has been able to collect only five instances of unusual intellectual precocity among physicians. One of these, Goethe, never completed the medical course. Cardan was an Italian physician in the sixteenth century who graduated and commenced teaching at 22. Boerhaave, the great Dutch physician, 1668-1738, was proficient in Greek and Latin when he was 11, but did not commence his medical studies until the age of 22. His famous pupil, A. von Heller, received his medical degree at 19. At 10 the latter composed a Hebrew and a Chaldean grammar for his own use, and at 15 had written several comedies, tragedies and an epic of 4000 verses. In our own day Flourens, best known for his physiologic researches, received his medical degree at 19. Oliver Wendell Holmes, while yet in his 'teens, wrote the poem "Old Ironsides," which prevented the breaking up of that historical vessel.

Societies.

Medical Society of the State of Pennsylvania, Philadelphia, Sept. 24-26, 1901.
American Electro-Therapeutic Association, Buffalo, Sept. 24-26, 1901.
Oregon State Medical Society, Portland, Sept. 25-27, 1901.
Utah State Medical Society, Provo City, Oct. 1-2, 1901.
Idaho State Medical Society, Pocatello, Oct. 3-4, 1901.
Tri-State Medical Society of Alabama, Georgia and Tennessee, Nashville, Tenn., Oct. 8-10, 1901.
Wyoming State Medical Society, Evanston, Oct. 8-9, 1901.
Vermont State Medical Society, Montpelier, Oct. 10-11, 1901.
New York State Medical Association, New York City, Oct. 21-24, 1901.

MISSISSIPPI VALLEY MEDICAL ASSOCIATION.

Twenty-seventh Annual Meeting, held at Put-in-Bay Island, Ohio, September 12-14, 1901.

Election of Officers.

The following officers were elected for the ensuing year: President, Dr. S. P. Collins, Hot Springs, Ark.; first vice-president, Dr. J. C. Culbertson, Cincinnati, Ohio; second vice-president, Dr. Paul Paquin, Asheville, N. C.; secretary, Dr. Henry E. Tuley, Louisville, Ky.; and treasurer, Dr. Thomas H. Stucky, Louisville, Ky.

Death of President McKinley.

The following resolutions were offered:

"Our President is dead. Our President, who accomplished the unification of our country; the abolition of sectional lines; the expansion which made us a world power, his last public utterance being in favor of peace, international reciprocity and sympathy, has been removed by the enemies of Society.

"We are overwhelmed with sorrow and personal grief for the death of the greatest of the world's rulers; for one who, from the standpoint of statesmanship, political foresight, sympathy with all the people, morality, the sweetest features of personal character and home-life, appealed to the appreciation of and affections of every citizen.

"A professional sorrow and disappointment taking the place of a hope that had inspired us from the first day the nation's calamity overwhelmed us.

"Joining in the personal grief and bereavement from which every true and loyal American citizen is this day suffering, we, the members of the Mississippi Valley Medical Association, in our twenty-seventh annual meeting assembled, do postpone the further presentation and consideration of special papers, in token of the love and respect with which we shall ever cherish the memory of our martyred President, William McKinley.

"(Signed.)
ANDRUS TIMBERMAN, M.D.
H. O. WALKER, M.D.,
I. N. LOVE, M.D.
Committee."

On account of the death of President McKinley, a motion was made and unanimously adopted by a rising vote, that the papers listed for the third day be read by title, referred to the Committee on Publication, and that the Association adjourn out of respect to the distinguished dead.

(To be continued.)

CALIFORNIA ACADEMY OF MEDICINE.

Regular Meeting held Aug. 27, 1901.

Dr. D. W. Montgomery, in the chair.

X-Ray Dermatitis.

DR. T. W. HUNTINGTON presented a man 35 years of age, who during last October was subjected to the *x*-rays several times, the result being an extensive dermatitis over the right rectus muscle above the umbilicus, over an area the size of a saucer. The case was presented to the Academy by Dr. Montgomery at the April meeting. At that time there was an elliptical area of skin necrosis, whose dimensions were three and a half by two and a half inches. It presented a dull mottle appearance. It was slightly moist, sluggish and parchment-like to the touch. Surrounding the ulcer there was a hyperemic zone, which faded gradually at its outer margin. The patient complained of intense itching, which at times was unbearable. At the junction of the necrotic and hyperemic areas there was marked [illegible] over the entire surface the pain was a consta [illegible] the courtesy of Dr. Montgomery the case came under the Doctor's care, May 9, 1901, and the following day entered the hospital. For two days strong antiseptic lotions were applied as a preliminary to operation.

On May 12, under chloroform anesthesia, the ulcer was circumscribed by a deep incision, extending through a thick layer of fat to the sheath of the right rectus. In dividing the layer of fat it offered so much resistance to the knife as to suggest an abnormal condition of that tissue. Accordingly the margin fat was also removed for a considerable distance from the periphery of the original incision, the overlying skin being left as a loose flap. This flap was then carefully sutured to the sheath of the rectus, and to secure a better lodgment for the grafts, the exposed sheath was removed up to the suture line. Upon the belly of the rectus, skin grafts, after the method of Thiersch, were adjusted and the wound was dressed with silver foil and dry aseptic gauze.

The patient made a quick, uninterrupted recovery, leaving the hospital. The recovery seems to have been permanent and he makes no complaint save of hypersensitiveness of a small area below the lower segment of the cicatrix. At this joint the skin is slightly reddened but there seems no tendency to necrosis, although the patient has been roughing it in the mountains for several weeks. The only feature of the case worthy of further comment is a keloidal ring encircling the grafted area following the line of cultures.

Dr. Dudley Tait said that there is a little point in the Thiersch graft that is of interest and that is the advisability of overlapping the grafts. He finds when the graft is not overlapped we get an area of granulation. If we overlap, a certain amount of skin disappears but there is a perfect line between the graft and the skin, and we do not get the cicatricial tissue that always accompanies the granulation tissue.

Dr. J. Henry Barbat said that with the *x*-ray there is no need to burn except where one treats with the *x*-ray and then you may get a burn. Even in that case there is no need to burn unless you want to. He has burnt a patient slightly on purpose to get the slight inflammatory action without severe burning, but there is no necessity now in taking a skiagraph and burning the skin.

Dr. D. W. Montgomery said that the patient came to him some time before Dr. Huntington saw it. He was then suffering excruciating pain. It was not only tender but spontaneously painful. Simple ointments such as balsam of Peru and red oxid of mercury ointment were tried with temporary benefit and then there would be a relapse. The best dressing was a 3 or 4 per cent. solution of lysol. This gave ease and comfort for some time and it looked as if the wound was going to heal, but then it became worse again. He showed it to the society and Dr. Huntington said he thought he had a plan for such a wound. The interesting part to me is that the Doctor went in under the skin and the skin was stitched to the aponeurosis of the muscle. All of the fat and a part of the aponeurosis were removed. It is very interesting to me to know that he went in, in a flaring direction, but I suppose that is the direction of the rays. The result is excellent.

Medication into the Epidural Space.

Dr. Dudley Tait read a short paper describing the anatomy and technic of puncture; he referred to the experimental work done by Cathelin, Laborde and himself. The epidural route was first described and proposed by Cathelin, an assistant of Guyon, shortly after surgeons had pointed out numerous dangers following the injection of cocain by the subarachnoid route. Sicard was the first to show its use in medical therapeutics. Up to the present time, this method has been used principally to check pain, as in sciatica, lumbago, herpes zoster, fulgurant pains, intercostal neuralgia, gastric and vesical crisis. In the domain of surgery epidural injections of cocain have not as yet given sufficient analgesia for operative work. Chipault alone has been able to perform several operations on the lower limbs by this method. The essayist tried it unsuccessfully in circumcision. Prolonged and pronounced relief has been obtained in inoperable cases of cancer of the rectum, in painful accouchements, cystitis, tuberculosis and dry arthritis. In four cases of incontinence of urine due to various causes, Albarran and Cathelin report almost complete cessation of the incontinence after two or three epidural injections of cocain. The quantity of cocain used by this route is from 3 to 4 centigrams in a solution of 1 to 200. Mauclaire recently made a series of epidural injections of iodoform emulsion in Potts' disease. His results have not yet been published. Huchard has used this route to administer various cardiac stimulants. Cathelin believes that this route may be used for the majority of soluble drugs; he strongly urges injections of cyanid or benzoate of mercury in malignant or cerebrospinal syphilis. Compared with the subarachnoid route the epidural method possesses many advantages from the medical point of view and up to the present time it has been spoken of favorably by the eminent physiologists who condemned in the strongest terms Corning's subarachnoid method.

Therapeutics.

[It is the aim of this department to aid the general practitioner by giving practical prescriptions and, in brief, methods of treatment for the diseases seen especially in every-day practice. Proper inquiries concerning general formulae and outlines of treatment will be answered in these columns.]

Treatment of Hyperchlorhydria.

Einhorn, as stated by *Phil. Med. Jour.*, recommends cold sponge baths in the morning for ten minutes before breakfast and light exercise during the day. The diet should be of that character which will most intensely excite the glands to action. Acids and spirits must be avoided and the food should be rich in albumin, and the starchy foods excluded. Three large and two small meals should be taken daily. Alkalies are indicated in the way of medication. From one-half to one dram of the sodium bicarbonate should be given three times a day about one hour after meals, with the addition of magnesia and rhubarb when there is constipation. When the nervous element is pronounced the following is recommended by Einhorn:

R.	Strontii bromidi	ʒiii	12
	Aq. menthæ pip. q. s. ad	℥ii	64

M. Sig.: One teaspoonful three times a day at meal time.

Palliative Treatment of Cancer of the Larynx.

A. Courtade, in *Laryngoscope*, gives this treatment in cancer of the larynx: The introduction of a suitable canula to produce easy respiration; check the hemorrhage by the use of perchlorid of iron or peroxid of hydrogen; diminish the quantity of secretion and the odor by instillation of mentholated oil, such as eucalyptus; prevent granulations by swabbing with pyoktannin.

Treatment of Chalazion.

The following combination has been used with success in the treatment of Meibomian cyst:

R.	Iodi puri	gr. iii	18
	Potassii iodidi	gr. vi	36
	Lanolini	ʒi	4
	Petrolati liquidi	℥iiss	80

M. Sig.: To be applied locally at night.

Treatment of Secondary Anemia.

Blackwood recommends the following combinations of iron and arsenic in the treatment of anemia:

R.	Euquininæ	ʒi	4
	Ferri lactatis	ʒii	8
	Liq. acidi arsenosi	ʒiss	6
	Tinct. lavend. comp.	℥ss	16
	Elix. aurantii	℥iv	128

M. Sig.: One teaspoonful four times a day in water.

Burns of the First Degree.

The following is recommended as a local application in burns before vesication has taken place:

R.	Acidi acetici dil	℥i	32
	Glycerini	℥i	32

Bismuthi subnit. q. s. to make paste.

M. Sig.: Apply to the affected parts.

Comparative Value of the Seed and Root of Colchicum.

It is well known that the value of the preparation of colchicum depends upon how it is prepared and from what prepared. Many preparations of this drug produce no results because of substitution of an inferior grade of the drug. The same may be said of strophanthus, gaultheria and digitalis.

These preparations, depending as they do upon their active principles for their efficiency in therapeutic use, should be selected with care and that part of plant made use of which contains the largest per cent. of the active ingredient.

Dr. L. Schulze, in *Western Druggist*, in speaking of the comparative value of the seed and root of colchicum, states that the seed contains on an average from .6 per cent. to .7 per cent. of the active principle. The root contains between .4 per cent. and .5 per cent. Consequently, he states, there should be no valid reason why the root should be retained in the pharmacopeia since the seed contains so much more of the active principle colchicine.

Sulphur in Dysentery.

Dr. G. A. Richmond, as noted in monthly *Cyc. of Med.*, recommends the following combination in the treatment of dysentery:

℞.	Sulphuris (sublimed)	gr. xx	1	33
	Pulv. opii et ipecacuanhæ	gr. v		33

M. Ft. chart. No. i. Sig.: One such powder to be taken every four hours until the diarrhea is checked.

Dr. Richmond states that in all his cases treated by the foregoing method, recovery has been rapid and the patients derived very speedy relief from pain and tenesmus. The blood and mucus were easily checked and relapses never occurred. As soon as the diarrhea becomes less it is desirable to give the powders less frequently.

Habitual Constipation.

℞.	Sulphuris loti	℥i	32	
	Potassii bitartratis	℥i	32	
	Pulv. sennæ	ʒiv	16	
	Syrupi rhei	ʒii	8	
	Ext. cascaræ sagradæ flu.	ʒii	8	

M. Ft. confectio. Sig.: One teaspoonful at night to move the bowels.

Vomiting of Acute Gastritis.

The following is recommended to suppress the vomiting in acute gastritis:

℞.	Vini ipecacuanhæ	ʒiv	16	
	Tinct. nucis vom.	ʒii	8	

M. Sig.: Take ten drops in water every two hours.

Treatment of Fissure of the Nipples.

Dombrovsky, in *Deutsche Aerzte-Zeitung*, recommends that the nipple be bathed several times a day with a 3 to 5 per cent. solution of potassium permanganate. He states that the first few applications are somewhat painful, but the pain soon disappears. Before the infant nurses the breast should be washed with warm water and the breast protected with some waterproof material having a perforation through which the nipple may project. He states that a cure will result in a week.

To Remove Dandruff.

The following combination is recommended to remove the dandruff from the hair:

℞.	Resorcin	ʒiss	6	
	Glycerini	℥i	32	
	Alcoholis	℥iss	48	
	Aq. rosæ	℥iii	96	
	Aq. destil. q. s. ad	℥viii	256	

M. Sig.: Apply locally and thoroughly rub into the scalp.

In Insomnia of Hysteria.

℞.	Pot. bromidi	ʒiv	16	
	Chloralis hydratis	ʒiii	12	
	Tinct. asafetidæ	ʒiv	16	
	Syr. simplicis	ʒvi	24	
	Aq. destil. q. s. ad	℥vi	192	

M. Sig.: One tablespoonful every three hours until sleep is produced.

Treatment of Acne in the Young.

The following is recommended by Brocq, as noted in *New York Med. Jour.*: The patient should eat of fat and butter sparingly and should abstain from the use of coffee, tea, pork, wine, pastry, cheese and spiced foods. The following preparation is advised to be taken at the beginning of each meal:

℞.	Sodii bicarb.	gr. ivss		27
	Magnesiæ (calcined)	gr. iii		18
	Pulv. cascaræ sagradæ	gr. iiss		15
	Benzonaphthol	gr. iiss		15

M. Ft. cachet No. i. Sig.: One such before each meal.

The face should be cleansed with pledgets of absorbent cotton and water as hot as can be borne, in which is boiled two teaspoonfuls of bran and a soupspoonful of sodium biborate to the quart.

At night the following ointment is to be applied to the spots:

℞.	Beta-naphthol (camphorated)	gr. ivss		27
	Resorcin	gr. iii		18
	Saponis nigri	gr. iii		18
	Cretæ preparatæ	gr. viiss		50
	Sulphuris precip.	gr. xxii	1	50
	Vaselini	gr. iii		18

M. Sig.: Apply locally at night.

In the morning the following should be applied after washing the face:

℞.	Sodii boratis	ʒiiss	10	
	Etheris sulph. camph.	ʒx	40	
	Aq. rosæ	℥iii	96	
	Aq. destil	℥ivss	144	

M. Sig.: Applied locally.

Mustard in Pneumonia.

In the *Post-Grad.*, Dr. L. Weber highly recommends the use of the mustard bath in the treatment of pneumonia, especially in children. He uses about one pound of mustard to one child's bath-tub of water. The child should remain in the bath ten minutes or until the skin becomes pinkish instead of blue. Friction must be carried on while the patient is in the bath. He should then be removed from the bath and wrapped in blankets. These should be repeated every second or third day.

Treatment of Hemorrhoids and Ulcer of Rectum.

Darche, in *Canad. Pract.*, has used with success the following applications in such cases:

℞.	Mercuralis	gr. v		30
	Chloretoni	gr. xv	1	
	Acidi boracici	ʒss	2	
	Petrolati	℥i	32	

M. Ft. unguentum. Sig.: To be applied three times daily.

In cases of ulcer of the rectum he used the following in the form of a suppository:

℞.	Mercurolis	gr. i		06
	Chloretoni	gr. ii		12
	Acidi boracici	gr. viii		5
	Olei theobromæ	gr. xxx	2	

M. Ft. suppos. No. i. Sig.: To be inserted at bedtime.

In cases of chronic gonorrhea he recommends the following in the form of a bougie:

℞.	Mercurol	1 per cent.
	Chloretoni	2 per cent.
	Acidi boracici	8 per cent.

M. Ft. bougies. Sig.: Insert night and morning.

Medicolegal.

Requiring Examination by Expert Oculist and Aurist.—The Supreme Court of the State of Washington holds, in the personal injury case of Myrberg vs. the Baltimore & Seattle Mining & Reduction Company, that the trial court has the power, within its discretion, to require a submission to an examination by an expert oculist and aurist where damages for alleged injuries to eyesight and hearing are claimed. But it does not think that an application to require a submission to such an examination was seasonably made, or that the trial court abused its discretion in not requiring it, when the application therefor was not made until in the midst of the trial when all the witnesses had been examined in chief on the one side, and several on the other, and it would involve a delay in the trial and loss of time for court and jury.

Attending Physician as Witness in Poisoning Case.—The Supreme Court of Oregon says, in the case of State vs. Simonis, that there is some conflict in the authorities as to whether a medical witness is qualified on a trial for poisoning to give an opinion that the symptoms indicate poisoning, when his knowledge was not obtained from personal experience or observation. But, whatever the rule may be in this particular, the books all agree that, before one can testify as an expert on that subject, it must first be shown that he is qualified to do so, either by actual experience, or such careful and deliberate study as enables him to form a definite opinion of his own in reference to the matter. Indeed, the definition of an expert, the court says, implies as much. It is one who has made the subject upon which he gives an opinion a matter of particular study, practice, or observation. He must have a particular and special knowledge upon the subject; and his competency, which is a question for the court, must be shown before he is permitted to testify. The mere fact of a witness being a regularly licensed and practicing physician the court does not consider sufficient of itself, as a matter of law, to qualify him to give an opinion as an expert as to the cause of the symptoms of his patients, as for example where poisoning is claimed. This conclusion it largely bases, in this case, on the fact of the act of 1889 regulating the practice of medicine providing that it did not apply to persons then practicing in the state, who, within a certain time, should register in the proper county office, while by the acts of 1891 and 1895 such persons were to be taken and considered as licensed physicians. It can not be assumed, it holds, that such a witness is entitled to testify as expert on the subject referred to. Furthermore, the court holds that a medical witness can not be asked to give his opinion, as a physician, as to what the general symptoms of a case indicated, the question not being so framed as to confine his opinion to facts previously testified to, but being intended to call for his opinion, based upon all the facts within his knowledge, whether stated or not. He must first detail the symptoms; then, if qualified, may be allowed to express an opinion based thereon.

Powers of Secretary of County Board of Health.—The Indiana statute makes the board of commissioners of each county a board of health ex-officio for the county. It then makes it the duty of the board to protect the public health by the removal of causes of disease, when known, and in all cases to take prompt action to arrest the spread of contagious diseases, to abate and remove nuisances dangerous to the public health, and perform such other duties as may from time to time be required by the State Board of Health, pertaining to the health of the people. Annually, the board is required to elect a secretary, who shall be its executive officer and shall serve as health officer for one year. Under this statute, the Appellate Court of Indiana says, in the case of Martin vs. the Board of Commissioners of Montgomery County, the county board of health has authority to protect the public health, and such expenses as are authorized by the board for the public benefit should be borne by the public. But this case presented the question of whether the secretary of the county board of health, irrespective of any action of the board of health, has authority to incur an indebtedness for which the county can be held liable. The court practically holds that he has not. It says that the statute makes the secretary the executive officer of the board, but it does not give him the powers the board itself has. If he has all the powers of the board itself, then the board is a useless body, and the only necessity for its existence is to elect a secretary each year. This was not the intention of the legislature. When the statute says that he shall be the executive officer of the board, it means that he shall carry out such orders and regulations as the board may make. If he has power, for example, to hire a pond of stagnant water drained and thereby abate a nuisance dangerous to the public health, he may do any act without authority from the board. There is no statute giving him authority to bind the county for such services. The statute creates a board of health, says who shall constitute the board, prescribes the duties of the board, and makes the secretary simply the executive officer of the board. If a nuisance is to be abated, that fact must be determined by the board of health, and not by the secretary. Whether, however, in a given case, an emergency might arise requiring immediate action by the secretary, the court says was not presented.

3. **Resections and Exsections.**—Henrotin favors radical operations in diseases of the ovary and tubes. He says he has performed at least 250 operations and can safely say that 40 per cent. may be termed delayed or partial cures or failures. Of this 40 per cent. the heaviest proportion by far comes from such patients as have had salpingotomy or tubal resection performed. The next most complaining class includes those patients in whom ovaries alone were resected, and the best results were obtained in those in whom the tubes were entirely exsected, and the whole or portion of the ovaries removed. The argument in favor of tubal resection that it saves reproductive power is not to be considered very valid, and he says that

when such an operation is performed for every baby born there will be 40 uncured or only partially cured patients. He does not wish to be classed among the ultra-radical operators, however, and the question how much of an operation should be done at each time arises even in these cases.

5.—See abstract in The Journal, xxxvi, p. 1493.

8. Gall-Stones.—The treatment of a case of gall-stone is discussed by Richardson, who favors early operation. As a rule the operation is easy, safe, rapid and effectual and remote dangers are avoided and lessened. If the diagnosis turns out to be wrong other lesions may be discovered, perhaps even more serious. The difficulties of determination between lesions in this locality causing pain is very great and the more appreciated by the surgeon the greater his experience. Late operations for gall-stones are difficult and dangerous. The *objections to the operation* are, first, the danger which, though slight, is worth considering and should be emphasized, though he does not believe that it equals the dangers that attend the passage of a single stone from the gall-bladder to the duodenum. The diagnosis is frequently wrong, but he does not believe that this necessarily prohibits exploratory operation. For one case of needless or hopeless intervention there may be many permanent cures. Hernia may result though it is not liable to be serious in the upper abdomen. It is, nevertheless, a disadvantage. The possibility of recurrence is considered, but he has never seen or had reason to suspect it after cholecystotomy and drainage. This argument, therefore, seems to have little weight. As regards the possibilities of spontaneous cure he considers the chances so remote and the dangers so great that it may be safely neglected. We have on the one hand slow and painful ulceration lasting for years and on the other, safe, rapid, intelligent and scientific work of a few minutes with absolute demonstration of a permanent cure which is impossible in other cases. The possibility that after offending enough to prove the diagnosis, gall-stones may give no further trouble should be little considered, unless where there are distinct contra-indications to operation; the other possibility that the last decisive attack of biliary colic may have been caused by the last remaining gall-stone is not of sufficient force to prevent exploratory operation. If one gall-stone begins to give trouble there is no telling where the process will end, except that the chances are that it will end in permanent disability or death, if let alone.

9. Obstruction of the Lower Bowel.—The various conditions in cases of obstruction are noted by Marcy with the therapeutic indications in each. The most important are those due to malignant growths, which unfortunately, however, come to the surgeon as a rule too late to hope for cure by complete removal. When the case has so advanced as to come within the strict limitation of his subject, that is, obstructive disease of the lower bowel, little can be hoped except palliation by colostomy. In his surgical experience he finds he has steadily enlarged the class of cases considered operable; he is governed much more by the evidences that the disease is absolutely local than by its precise location. Any circumscribed growth limited to the portion of the bowel within reach of the finger in either sex is operable. If there is distinct evidence of glandular infiltration it is doubtful whether operation is advisable, and here relief is experienced and life prolonged by colostomy. He speaks well of the Kraske operation in some of these cases as giving an enlarged field of operation and affording the possibility of removal of many of the pelvic glands. Abdominal section in the Trendelenburg position is also noticed; resection of the lower bowel for cancer by approaching it from above in many instances is a very great advantage in modern technique for a variety of reasons. The lymphatic glands of the pelvis can be examined and removed as by no other route. Resection may be made much more accurately, and in many instances the function of the lower bowel preserved and restored.

10. Malignant Disease of the Stomach.—Cumston sums up that the surgical treatment of carcinoma of the stomach is indicated not only when the stenosis is present, but *also* as a radical cure of cancerous disease. If it has radically cured a few patients only, it has at least given, in more than 33 per cent. of those operated on, a new lease of life of from one to eight years, while the mortality has been reduced to 20, 15 and even 10 per cent. In every case of suspected carcinoma an immediate exploratory laparotomy should be advised and every new growth that can be removed should be taken out no matter what its nature may be. A confirmed diagnosis of cancer of the stomach should not be waited for as exploratory laparotomy is justified in every case where the patient is affected with gastric troubles when: 1. An analysis of the gastric juice shows absence of pepsin, or the presence of lactic acid. 2. When medical treatment carefully conducted does not increase the body weight and keep it there. The indications are those drawn from the general condition of the patient and the presence of visceral metastases demonstrated by palpation or exploratory incision as well as from the immobility and adhesions of the tumor and the propagation of the neoplasms beyond the movable portions of the duodenum or esophagus. The age of the patient, presence of some enlarged glands, size, position and extent of the new growth in no way contraindicate operation.

12. Leucocytes.—Williams suggests a change of name for Ewing's classification of leucocytes, using the terms acid, neutral and alkaline instead of basophile, neutrophile and oxyphile. In all three classes the nuclei, like the bodies of the normal single-nucleated leucocytes, take the alkaline dyes. The normal, many-nucleated leucocytes are neutral to dyes as are also the neutral myelocytes, which are found only in disease. The bodies of the so-called eosinophile leucocytes and myelocytes take only the acid dyes. They are, therefore, alkaline. The alkaline leucocytes, he thinks, occur chiefly in disease and any marked increase in their number is sure to be a pathologic symptom. He suggests that the presence or absence of nuclei is a condition on which the taking up of acid dyes depends and that the alkaline leucocytes are the dyeing forms. He therefore includes all alkaline leucocytes under the designation of necrotic cells. This opinion is supported not only by their presence in disease, but by their association with xanthine and spermin, which are the products of decomposition of nuclein.

13. Yellow Fever in Havana.—The methods of sanitation adopted in Havana are described by Gorgas. Since the demonstration of the mosquito origin of the disease, a complete change has been made in the system of quarantine. A certain number of rooms selected by the physician and patient's family are quarantined, completely isolated by nets made mosquito proof, and *all mosquitoes in adjoining rooms* and even in adjoining houses are destroyed as far as possible, and the insecticide methods adopted. The results are very striking. The disease seems to have been almost absent during the present year, at a time when it should be most prevalent. The city is divided into eight districts for the purpose of destroying mosquitoes by the use of oil, mosquito-proof receptacles for water, etc. He says in conclusion, there being a very large non-immune population in the city, and yellow fever having been introduced into the city on a dozen different occasions, they have so far managed to keep it out later than has ever been done before. Even if it should occur later in the season, he feels confident the destruction of mosquitoes is the proper method for fighting the disease and that we shall be eventually successful on these lines.

15. Nasal Catarrh.—The importance of finding the source of infection in cases of nasal catarrh is emphasized by Cobb, who reports several cases demonstrating his points. Each case, he thinks, must be carefully studied, and it may be a question of weeks and even months before we can be certain of the cause, but if we bear in mind that chronic discharge in the throat is caused in the same way as chronic discharge in other parts of the body, and study the cases in this light, we should be able to treat it intelligently. His experience has led him to believe that the disease is curable. Some of the cases were cured by the treatment of antral disease, others by removal of portions of the turbinate and in one case the diseased root of a tooth was the cause of the condition.

17. **New Continued Fever.**—In the spring and early summer of this year Spratling has observed what is to him a new fever in his part of Georgia. It begins with malaise, muscular pain, especially in the neck, slight chilly sensations, temperature rising at once to 102 F. sometimes, pulse from 112 to 120, respiration to 30 or 40; nausea was present, a hacking cough and mental depression; later the pains were more pronounced, and headache severe, with photophobia and dizziness on rising; the temperature was 104 to 106 F., pulse 120 to 140, respiration 40 to 60; the abdomen was sore and tympanitis, there was anorexia, and scanty, offensive and highly-colored urine. The mind was periodically clouded, often actively delirious, according to the temperature, which changed rapidly, sometimes four or five fluctuations in twenty-four hours; the slightest noise, disturbance, or exertion, mental or physical, causing rapid exacerbations. The cases differ from dengue in the very widely varying symptoms. In several cases the temperature reached 106.5 F., and the influence of environment was very marked, which also differed from dengue. There was also no involvement of whole families; the cases were isolated. The symptoms lasted from two to five days, then gave way rapidly, but the fever and scant urine persisted for several days longer, and there were frequently profuse sweats. We have here, he thinks, a close relative, if not actually the same thing as Malta or Mediterranean fever. In about one-half of the 60 cases the disease was mild. The longest course was twenty-three days. The prognosis was good when no organic heart lesion existed. The kidneys were stimulated with alkaline diuretics and depressant medication avoided; strength preserved and quiet maintained. Tests for malaria and typhoid fever failed to give any reactions; and these diseases are rare in that locality.

18.—This article has appeared elsewhere. See THE JOURNAL of August 31, ¶68, p. 603.

19. **Light Treatment.**—Hopkins describes his methods of using light and the *x*-ray. In cancerous growths he prefers soft tubes and has found the static machine worked by an electric motor preferable to the alternating current. For the protection of the parts not to be treated he uses several layers of lead foil, glued to pasteboard or more flexible material, making an opening where the rays are desired to act. The theory on which he advocates the use of the soft *x*-ray tube in the treatment of carcinoma is that the power to produce changes in the tissues must be proportionate to the resistance which the cells of the tissue to be acted on offers to any destroying agent. Theoretically, the longer wave of the soft tube, as compared with the harder tube, has more destroying and disintegrating effect. He reports a case which he thinks was cured by this method. The first effect in all the cases is decrease in the density of the tumor. This change in consistency governs very largely the time of exposure. If the time is too long necrosis would occur, which should be avoided.

20. **Epilepsy.**—The temperature in epilepsy has been carefully studied by Spratling, who notices Bourneville's conclusion that isolated attacks augment the central temperature. His own observations agree in part only with Bourneville, who does not classify the types of seizures studied or make due allowance for certain physiologic conditions. After making due allowance for diurnal variation, he finds that 40 per cent. would be the lowest of such cases showing increased temperature after seizures, and 70 per cent. the highest, making the general grand average of cases showing increased temperature after seizures 55 per cent. The part played by muscular activity in creating heat is noted and its action in these cases wholly irrespective of any influence exerted on the cerebral heat centers. In many petit mal and psychic attacks in which muscular activity plays a small part and in which the temperature is increased after seizures, such increase is due to disturbance either of the cortical heat center or centers, or of centers that observers believe have been located in the corpus striatum and optic thalamus. He finds that subnormal temperatures follow epileptic seizures after grand mal more than after petit mal or psychic seizures, the proportion being 15 per cent. of the former to 10 per cent. of the latter types; and while he agrees in the main with Lemoine in considering such cases as anomalous in having abnormally low temperature in health, he does not consider this explanation quite sufficient. There will usually be found in these cases some chronic disease or general asthenic condition of long standing that lowers the stamina and vitality of the individual. All that has been said by Bourneville, Lemoine and others in reference to the high temperature in status epilepticus is confirmed by his observations. The temperature in serial attacks runs uniformly higher than in isolated attacks, but not so high as in status, serial attacks occupying a middle ground, between the two. As a possible factor in establishing the presence of toxins or other agencies in the body prior to and possibly causing the convulsion, an effort was made to take the temperature in some cases when the aura was of sufficient length, before the attack, but was successful in only one case where the heat began two hours before the fit, when it ran steadily up to 102 F. and the patient passed into convulsion.

26. **Typhoid.**—The details of hospital treatment are given at length by Bellamy with special reference to the nursing, dieting, bathing methods, etc. He has not had much success with the ice tub, but believes that systematic tubbing on modern lines is the most advantageous. The methods used in the Johns Hopkins Hospital are described and illustrated by plates, as is also the author's bathing apparatus. As regards other methods he mentions the use of saline baths, which he thinks are of practical advantage in many cases, also olive oil inunctions following these to relieve the irritation caused by the salt. He believes in the use of turpentine if tympanites exists and sweet spirits of niter and digitalis in small doses, strychnin sulphate, etc. When convalescence occurs he insists on the necessity of care as regards diet, etc.; as much care and consideration should be given the patient as during the stage of pyrexia.

29. **Whooping Cough.**—The treatment suggested here by Mays is the use of counter-irritants over the pneumogastric nerves, which he says is the only method that has ever given him good results. The practical way of applying the remedy is as follows: Trace the pulsating carotid artery from behind the angle of the lower jaw to the clavicle on both sides of the neck. This will be a landmark for finding the pneumogastric nerves which lie in close proximity and slightly behind the carotids. Gentle massage and kneading of this region of the neck, every hour or two, yield beneficial effects in many cases of this disease. The application of a strip of mustard plaster, about two inches wide, from the angle of the lower jaw to the clavicles on each side of the neck, two or three times a day, until the full effects of the mustard are evident, is almost sure to cause amelioration of the spasmodic cough. Equal parts of gum camphor, chloral hydrate, and menthol, applied over this region, are also very useful. Painting the same area with tincture of iodin, twice a day, until irritation of the skin is produced, is a beneficial procedure. Finally, in very stubborn cases the hypodermic injection of silver nitrate over the vagi must be resorted to in accordance with the following plan: Lift the skin over the vagus between the thumb and the forefinger of the left hand, introduce the hypodermic needle just under the elevated skin, and inject five minims of a two-and-a-half-per-cent. solution of cocain hydrochlorid. Detach the syringe from the needle and allow the latter to remain in the puncture. Wash out the syringe with water, draw a two-and-a-half-per-cent. solution of silver nitrate into the syringe, attach the latter to the needle, and throw in from three to six minims of the silver solution. Under this treatment he says the child becomes more comfortable, the paroxysms less frequent and the severity of the cough decreases. The affection assumes a different character even in a day or two.

FOREIGN.

Revue Hebd. de Laryngologie (Bordeaux), July 27.

Acute Inflammatory Edema and Abscess of the Larynx. LUBET-BARBON.—The principal indication is to gain time. The edema will become stationary in forty-eight to sixty hours and subside after three to four days. Antiphlogistic measures internally and externally, possibly leeches, hot fumigations, wet packs around the neck, a 1 to 1000 carbolized spray and insufflations of morphin are some of the measures recommended. If the abscess points, incise immediately. In 3 cases observed by the writer this intervention revealed pus and relieved the patients. Intubation or tracheotomy is the last resort. Nineteen cases are reported, including several of personal observation. Only one patient was a child. The edema may be due to irritation from a foreign body, to a chill or other cause favoring infection, which is produced by various germs. The dyspnea may be the first symptom and appear suddenly. Inspiration is difficult and whistling. Expiration is protracted and croupy. The patient is unable to cough or expectorate as the dyspnea is increased by the slightest effort of the kind. He can not sleep for fear of suffocation, and the waking coma is due not only to the fatigue from sleeplessness but to the slow anoxhemia, the consequence of the dyspnea. Dysphagia is so pronounced that the patient feels as if a sharp instrument were in his throat at every effort to swallow. There may be fever and chills. Two cases are on record in which the removal of the obstacle by tracheotomy failed to prevent the fatal termination.

August 10.

Aberrant Mastoid Cellulitis. J. Toubert.—Osteitis from an otitis of the middle ear developing at a distance, beyond the antrum, is a rare affection. The aberrant abnormal cell in which it occurs is always retro-antral or mastoido-occipital. This cellulitis in Moure's case proved fatal. In Richard's it caused hemicrania, nausea and vomiting. The lymphatic or venous route was evidently the source of contagion, as there was no direct connection between the middle ear and the aberrant cells in the four cases on record. Recovery was remarkably rapid after evacuation. The abundance and the persistence of the suppuration indicate its origin in the bone.

Revue Mensuelle des Maladies l'Enfance (Paris), August.

Treatment of Old Forward Luxation of the Radius. Broca.—The technique advocated is the resection of the head of the radius if it will not stay under the condyle after reposition on account of the rupture of the ligament in front. After the head is removed, the stumps of the ligament can be brought across the small neck and sutured, thus holding the radius in its normal position. The functional results in a case described were perfectly satisfactory. The patient was a lad of 7 and the luxation had occurred eight months previously.

Heart Disease in Children. Marfan.—Mitral insufficiency from endocarditis, without other lesions, in children is sometimes curable. When it persists, it causes little if any functional disturbance while childhood lasts. If asystolia, *that is*, symptoms of insufficient contraction of the left ventricle occur, some other lesion must be present, probably congenital. An idiopathic endocarditis sometimes develops in children. It is more severe before 4 or 5 than after this age, and most frequently affects children with some congenital lesion. Acquired lesions of the aorta are very rare in children. Marfan has observed 3 cases and been able to find only 24 in the literature. They are of a rheumatismal or atheromatous type. The former includes pure aortic insufficiency, with the same manifestations as in the adult, although the functional disorders are less pronounced. This tolerance diminishes with age. Aortic insufficiency associated with aortitis, is a second variety. True stenosis of the orifice of the aorta is exceptional in children unless congenital. This variety, with its double souffle at the base, is more serious than the first. The lesions are diffuse instead of circumscribed. There may not be angina pectoris, but pain occurs frequently in the sternum, without distress or irradiation. The attacks of suffocation sometimes suggest asthma, sometimes dyspnea with pallor and vomiting, but they last only a few seconds. In the third variety, the lesions are associated with some alteration of the mitral orifice, and in the fourth and last, with pericardial adhesion. The latter causes, in children, recurring asystolia with brief intermissions. Only a few instances of atheromatous lesions in children are on record. They usually appear under the form of a chronic aortitis with a systolic souffle at the base, usually erroneously attributed to stenosis. If isolated, it causes little trouble. In one case, neuralgia of the phrenic nerve was the only symptom, but it may lead to an actual aneurysm or induce fatal asystolia. This insufficient contraction of the left ventricle, in children, is usually due to pericardial adhesion, but occasionally to an acquired endocarditis complicating a congenital cardiac lesion. After 6 years of age it is almost invariably due to pericardial adhesion. In children, the heart rhythm is usually preserved. Tricuspid insufficiency is very rare, as is also apoplexy of the lungs, while the hepatic phenomena predominate. The liver remains comparatively enlarged even during the intermissions. In rheumatismal pericardial adhesion, the heart is hypertrophied, while in the tubercular variety it is of normal size or even smaller than normal. Edema, cyanosis and the cardiac liver are common to both. The cardiac liver in these cases tends to cirrhosis, and the exaggeration of the symptoms may simulate a tubercular peritonitis or alcoholic cirrhosis, and perihepatitis may obscure the picture still more. Digitalis must be given at the slightest suspicion of insufficient contraction of the left ventricle. Marfan prefers a maceration of 20 to 40 cg. of the pulverized leaves in 60 to 100 gm. of cold water, strained after twenty-four hours and administered at one dose in the morning before breakfast, for five or six days to a child of 5 or 6. He then substitutes .75 gm. of theobromin for a child under 6 and 1 gm. after this age. This stimulates the renal function. Digitalis again after ten days if necessary. Caffein may advantageously supplement these measures, one subcutaneous injection of 10 to 20 cg. of caffein for two or three days. A purgative should not be given before the digitalis, as it may start a diarrhea hard to control. Sometimes the diuresis is not established until ascites has been relieved by puncture. Absolute rest in bed is essential, and a milk diet, with possibly revulsion over the heart with methyl chlorid, etc. By these measures an impending attack of asystolia may sometimes be averted. To forestall the tendency of the cardiac liver to cirrhosis, Marfan gives calomel every fifteen to twenty days, 5 cg. in five doses at half-hour intervals in the morning.

Archiv f. Kinderheilkunde (Stuttgart), xxxii, 1 and 2.

Radioscopy of the Chest in Children. G. Variot.—Radioscopy of the chest in pneumonia in the adult is difficult, but children can be wrapped up warmly and carried to the apparatus in another room without discomfort or danger. The results of radioscopy in genuine croupous pneumonia confirm those obtained by percussion and auscultation and frequently afford information when the latter fail. It is possible thus to differentiate pneumonia from meningitis, especially when the solidification is taking place and the slightest difference in the transparency of the lung is plainly perceptible. It reveals centrally located pneumonic foci which have hitherto baffled all diagnostic measures. It is more difficult of interpretation in case of bilateral bronchopneumonia on account of the lack of the sound lung for comparison. There is merely a slight decrease in the transparency of the parenchyma, most pronounced with confluent foci, especially the pseudo-lobar forms. The edge of the heart shadow is vague as it blends with the opacity of the parenchyma.

Atresia of Larynx After Intubation. G. v. Ritter.—A child of 16 months exhibited suddenly symptoms of laryngeal stenosis, requiring intubation, suffocating as soon as the tube was removed. Tracheotomy was therefore done after a few days; four days later the larynx was found to be completely occluded just above. The child died from intercurrent measles and autopsy confirmed the complete obstruction of the larynx just above the tracheal wound, corroborating *O'Dwyer's* assertions in regard to the possibility of this occurrence after tracheotomy during inflammation. Since then Ritter has made a practice of continuing the intubation indefinitely if necessary, gradually substituting smaller and shorter tubes until in his five cases he found that the children—all between 15 months and 3 years—were cured without the necessity of further intervention. The intubation was continued for twelve to thirty-two days. The tube was coughed out sixteen times in one case.

Iron in Mother's Milk. J. K. Friedjung.—One of the disadvantages of the artificial feeding of infants is probably the lack of the iron which is always found in the normal milk of healthy women—in a proportion of 3.52 to 7.21 mg. to the liter in twenty-one cases investigated. The women were 19 and 27 years old, the infants 10 days to nearly 10 months. When nurslings do not thrive on apparently normal milk, the proportion of iron is usually found to be subnormal.
